According to the data sheet for the Votrax SC-01 speech-synthesizer IC, only 70 bits per second of data are required for continuous speech production. If you can prepare what you want to say in advance, this provides a way to have "speech" over extremely narrow bandwidths. It would also provide a way for a visually impaired person to communicate with RTTY.

As I mentioned before, a synthesizer based around SC-01 is programmed using phonemes—the basic speech *sounds* of English. There are 64 phonemes—this means that only 6 bits need to be transmitted for each sound (since any digital code is now legal, within band limitations, there is nothing wrong with using 6-bit "words"). Votrax has symbols associated with each phoneme to make transcription easier. For example, "catalog" would be K AE2 EH3 DT UH3 L AW2 AW2 G, and "empty" would be EH2 EH3 M P T Y. The phoneme symbols that end in a number (EH2, EH3, etc.) are for vowel durations. Phonemes that end in a higher number are for short-duration vowel sounds.

With a bit of practice, one can encode text into phonemes very quickly. A text-to-speech program, such as the one available from MicroMint (917 Midway, Woodmere NY 11598) for the Apple II computer, permits the user to simply type the text in English and let the computer worry about the conversion.

Receiving phoneme-encoded data over the air is a simple process. Just feed the received data, through a buffer, into the speech synthesizer. All the buffering and controlling can be handled easily with a short machine-language program.

Since this "mode" is not a true speech mode, in that one must type one's transmission rather than speak it, it is not suited for conversational communications. An appropriate application would be for radio bulletins and similar one-way communications, where the transmitting station has prepared the message far in advance.

A novel use of this technique might be to have a "subcarrier" voice channel on an FM repeater. By FSKing the repeater's output, a few stations can receive the data using the discriminator output on their FM receivers. Any station using the repeater for conventional voice communications would not be able to notice the small frequency shift on the repeater. Such a subcarrier channel could be used to transmit repeater-status information, club bulletins, weather reports, etc.

Other Speech-Synthesis Techniques

There are a number of speech-synthesis techniques available. Phoneme synthesis, the technique just described, requires a very low data rate (70 bps). Speech quality, however, is not that good. It is understandable but requires a bit of getting used to. (An analogy is the "monkey chatter" of SSB. It sounds strange to people who have never heard SSB before.)

If one wants better speech quality, there are two choices: linear predictive coding and speech digitization. Linear predictive coding (LPC) is what Texas Instruments uses in its "Speak and Spell" talking toys. The technique involves analyzing human speech with computer and breaking it down into sound components. To reproduce these sound data, they are fed into a circuit which, by simulating a human vocal tract, reconstitutes the data into fairly natural sounding speech. Unfortunately, to encode LPC data, time-consuming algorithms are needed. Because of this, the calculations are usually done on mainframe computers or large minicomputers. The encoded data take up more room than phoneme-encoded speech, per second.

Speech digitization is much like using the computer's memory as a tape recorder. Speech is analyzed with an analog-to-digital converter—samples are taken at a rate of 12,000 per second. The data from

the A/D converter are stored in memory. To recreate the sound, the data are played back into a digital-to-analog converter, which is connected to an amplifier. Digitization uses a lot of memory—64 kilobytes can only hold a few *seconds* of speech. The quality, however, is extremely natural sounding.

As you can see, there is no "best" way. Each method has distinct advantages and disadvantages. After working with phoneme synthesizers for a number of years, I tend to favor them. The speech sounds much like one would expect a computer to talk—with a heavy monotone "robot" accent—but considering the memory efficiency that a phoneme synthesizer offers, it is one of the best methods around. It's also the only method that can provide an unlimited vocabulary without extensive preparation.

Phoneme-synthesized speech can be a useful and practical part of a digital communications system. In addition to using it as a narrowband speech technique, it is useful in providing voice output on a RTTY mailbox—stations without RTTY (or mobile stations) can hear what messages are in memory. I will update speech-synthesis technology as more hardware becomes available.

REVIEW

NOVICE GUIDE FROM BASH

Bash has done it again! The all-new *Novice Class Amateur Radio Operator Guide* is now available, and it's a beauty.

No, don't expect the old *Final Exam* book, and don't expect to get the exact answers to every question on the Novice examination, because the *Guide* is not that kind of a book. This time, due perhaps to the new FCC requirements (which are covered by the *Guide*), the format is tutorial, but not pedantic or dull. It is light, easy to read, and *fun*! Virtually everything the prospective Novice will need to know to pass the theory portion of the exam is included.

Let's take a look at some specific features covered by the guide, as well as the mechanical specifications. The book itself has a soft cover with a glossy finish in light blue and black, measures 6" × 9" × ¼", and weighs only a few ounces... exactly the neat, easy-to-carry size that you will find convenient to take with you but not so small that it will be hidden under the piles of things on your desk, table, or bench. Of course, you can't judge a book by its cover, size, or weight... you have to look inside.

Divided into 26 convenient chapters or sections with such titles as "In the Beginning," "The Rules Jewels," "Zip Zap: About Lightning," "Shorties," "So What Do I Say Now?", and the like, the *Guide* tells you neither too much nor too little, but gives you exactly what you need to know to pass the exam.

As many of you know, the FCC has now followed a long-time practice of the FAA with respect to exam questions—that is, the questions that will be asked on examinations are published. That's right, THE questions! So, what's the trick, you ask? Well, the trick is that they choose only one question out of a possible ten or twenty in each of twenty categories covering the subject matter you are supposed to know. Therefore, it doesn't do any good to memorize specific answers to particular questions... you have to know the basic material. Knowing that, you will be able to answer any questions asked, and that's the way it should be. If you read the *Guide* and understand what it teaches and are able to answer the practice questions, then you will be able to take the Novice examination with full confidence that you will pass. You'll be able to answer any question in any category.

The *Guide* provides a catch-all chapter covering many miscellaneous questions that don't fall conveniently into any of the twenty categories. Dick Bash doesn't want you to be caught by any surprise questions.

A very helpful chapter is "So What Do I Say Now?" It covers the Novice version of mike fright—a condition that often occurs when you are making your first half-dozen or so contacts. Let's say you call CQ and suddenly, magically, receive an answer. Maybe it's a more experienced Novice on the other end, and he seems to be sending so fast that even your call (much less his call) is barely recognizable. Before you know it, he has signed over to you... and there's a great dead spot on the band, waiting for your answer. You shake, you sweat, your fingers cramp, and you are scarcely able to send your call. You think, "Oh my gosh, he's waiting for me to say something, and I don't know what to say!" Enter Bash, stage left, to help you out of the dilemma. He gives you sample exchanges, things that are said by both sides in a typical CW exchange. You could almost copy the information verbatim, or you can vary it to suit your own special case by merely changing a word or two here and there. It does get you over those first few critical moments when everything goes blank.

There's much, much more, of course, to the *Guide*, but we don't want to spoil it for you by telling you everything that Dick Bash has up his sleeve. Join in the fun. Give the *Guide* to a son or daughter, a friend, or anyone who might be thinking of taking a Novice exam. Here's a thought: Maybe you will be giving the Novice exam yourself to some potential hams in the club or neighborhood, and you're saddled with teaching the course. If you need a syllabus and text to work from, you could use the Bash book for this purpose, too. In fact, I'll bet that you will find things there that even you have forgotten. Heck, it'll cost you only a well-spent $9.95 (cover price) from *Bash Educational Services, PO Box 2115, San Leandro CA 94577.* Reader Service number 476.

THE COMPLETE DXER

Few enjoyments surpass the comfortable pleasure of settling in for an evening's reading of a good book in a snug and cozy environment. For best results, the book should be interesting—which could mean entertainingly written or instructive, preferably both. It should be fact-filled, yet exciting enough to move the reader quickly through the action, never permitting boredom. Most of all, a good book should fascinate the reader and, when possible, place him or her right in the middle of the action. The reader then becomes immersed and is no longer aware of being a reader; instead, he becomes a participant... involved in the story. Time loses meaning, and the story is all. You will find Bob Locher W9KNI's *The Complete DXer* such a book.

Written by an experienced DX chaser, yet clear and simple enough for the beginner, the book tantalizes and teaches at the same time. It recognizes that we all start as beginners, but, more than that, it helps us learn to do things the right way, to avoid the traps and pitfalls waiting to turn a neophyte into a lid, until the goal is in sight—the DX Honor Roll. If you're not on your way to Honor Roll after reading and practicing Bob's brand of DXing magic, then the fault will be yours, not his.

The Complete DXer can be a reference and a guide... a welcome companion to be savored at leisure. Most assuredly, it represents a solid-gold treasure trove of information amassed by a skilled operator during a lifetime of DX chasing. After reading the brief foreward and acknowledgements, you are plunged into Chapter 1, "A Night on the Bands," a foray into the DX jungle of twenty meters on an evening when the band is open. You're there when Bob stalks—and bags—a rare A71 station on Qatar, beating out the rest of the world for this big-game trophy. Then, almost before you can recover your breath, you happen upon the trail of a T55 but don't manage to track him to his lair before he disappears. Bob has managed to decipher his wily habits, however, and you know that next time, Somalia will be yours. This chapter creates the desire to know more, to become a patient and skillful hunter, so you can go out on your own and capture your own DX prizes. You learn that listening and patience and skill mean more than raw power, setting the stage for Chapter 2, "Basic Listening."

The first section of the book deals with basic and intermediate skills and equipment. What to use, where to find it, how to use it... a primer of great and lasting value. The second section of the book builds upon the first, adding refinements of technique, special tricks of the trade, and how to be a sportsman in the truest sense of the word. It teaches you about "Winning, Losing, and Playing the Game." Finally, Bob teaches you his "Last Secret" before turning you loose on the unsuspecting world. In "Conclusion," you are left with a philosophy and a new beginning.

Just the other day when I was talking with Bob about his book, he asked me how I liked it. I gave this answer: "I wish I had written it"—the ultimate accolade... and the truth. *The Complete DXer* is bound to be a smash hit, so you had better get out the checkbook right away and put in your order before they're gone. The price is $10.95 plus $2.00 postage and handling. VISA and Mastercard are accepted. It's available from *Idiom Press, Box 583, Deerfield IL 60015.* Reader service number 477.

AWARDS

DAVY CROCKETT

On April 28, 1984, the Bryan Amateur Radio Club will run a special-event station in the Crockett National Forest to commemorate the contributions of Davy Crockett to the fight for Texas independence. The club will operate W5RAS from 1800 UTC Saturday to 0600 UTC Sunday on 80–2 meters on the phone bands. Certificate for $1 and an SASE to QSL manager KA5OIT, 2203 Franklin, Bryan TX 77801.

TATER DAY

The Marshall County ARA will be operating a special-event station from 1800Z April 1 to 2400Z April 2 to commemorate the 141st Tater Day Celebration. Operation will be on CW, 7120. Operation 20 kHz up from lower 40-15-meter General phone-band edges and 146.55 simplex. Certificate will be given. Send QSL and large SASE to WG4U, Route 2, Benton KY 42025.

X-WARN

X-WARN (Xenia Weather Amateur Radio Net) announces the planned operation of special-event radio station WB8QZZ on March 31 and April 1, 1984. Our operation commemorates the rebuilding of the Xenia community on the 10th anniversary of the killer tornado of April 3, 1974. This triple twister damaged half of the homes and businesses in a city of 25,000 and killed 33 persons. Amateur radio contributed immensely with emergency communications in the hours and days after the storm. X-WARN was organized subsequent to the tornado as a means of providing prompt local weather observations during National Weather Service alerts.

The special event will operate two HF transceivers from 1500 to 0300 UTC on Saturday and 1500 to 2300 UTC on Sunday. Frequencies will be SSB: 7.275, 14.275, and 21.375 (± 10 kHz). We will also have a third rig on 2-meter FM: 146.52 simplex or the X-WARN repeater 147.165/765. Please send QSL and SASE to N8CYS (per *Callbook*) for special commemorative QSL.

ARBOR DAY

A special-events station will be operating from the Nebraska State Arbor Lodge, former home of J. Sterling Morton (founder of Arbor Day), in Nebraska City, Nebraska, during the annual Arbor Day celebration. This station, in addition to other club-member stations, will be operating in the General portion of the phone and CW bands on 80 through 10 meters from 2400 UTC April 27 to 0600 UTC April 29. In addition, other club-member stations will be operating from their own QTHs from 2400 hours UTC April 23 to 0600 hours UTC April 29. All amateurs contacting this station, K0TIK, or any other club-member stations during these times will be eligible to receive an Arbor Day commemorative certificate from the Nebraska City Amateur Radio Club. Please send one dollar and a business-size self-addressed envelope to John K. Nihart KA0OKI, 7731 Holdredge, Lincoln NE 68505.

HAM HELP

I have recently purchased a Radio Shack TRS-80 model 100 and would like to know if there is any ham software available for it commercially. I am particularly interested in any CW send/receive and RTTY software and would appreciate having the names of any companies that might have such systems. Information about software for other computers that run Basic would even be helpful, as I think that I could adapt it for the model 100.

David C. Eanes N4AZI
4866 Drusilla Lane
Baton Rouge LA 70809

I want someone to have a sked with me to increase my CW speed. Must use keyboard and start at 25 wpm. For more info, call (304)-983-2157.

Roger Vankirk KX8Y
Rt. 2, Box 388X
Morgantown WV 26505

I would like to hear from anyone who has modifications to put the Ten-Tec Omni on 10-meter FM.

Stephen J. O'Malley N2CLE
140-26 Poplar Ave.
Flushing NY 11355

I need a service manual or schematic or copy of same for a Yaesu FM FT-202R handie-talkie. Also need crystals for 2 meters or charger.

Spokane WA 99204

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

TV-10 to see if I've guessed right about hand TV sets.

Speaking of Sinclair, the absence of Timex from The Winter Consumer Electronics Show was most obvious. Last year they made a big fuss about introducing the Sinclair Spectrum, only to change their minds when the Model 1000 was bombed out by the VIC-20.

Timex, which has been quite stand-offish to firms interested in supporting their computers with a magazine or software, is paying the piper for this bit of folly—to the tune of hundreds of millions of dollars. They fired the people who engineered the disaster, but it is probably far too late now to recoup. Texas Instruments pulled the same stunt, with even greater losses.

Despite the dead and badly wounded microcomputer manufacturers, the industry itself is still growing at about the same 250% per year rate. It's just that Timex, Texas Instruments, Atari, and so on are not getting big chunks of it. Radio Shack has been holding on. Apple is at the crossroads, gambling everything on their Macintosh.

All of this has been a bonanza for hams who early on got interested in computers and who have jumped aboard the industry. The micro industry is rife with hams, as I see when I'm stopped by hundreds of old *73* subscribers at the Comdex and CES shows. Many claim that it was my editorials and articles in *73* that got 'em into computers—and rich.

The next big field, as I've written before, is going to be communications. Some ham is going to design a simple radio system to automatically send messages and parlay that into a $500 message communications system for private aircraft which will eliminate the need for voice communications between pilots and towers. This chap could easily get extremely wealthy. The nice thing about this is that everything needed for the system has already been invented. All it takes is an experimenter to put it together, test it, and find a venture capitalist to back him. Eureka! Millions. And, you know, a kid of 15 could do it.

Let's get some work done and get some articles in *73* to spur more experimenting. It's possible for hams to again get up front in developments and regain some of the prestige we once had. The FCC is off our backs now, so we can experiment.

COME FLY WITH ME

Are you looking for some small electronic or ham product from Asia which you might import and sell by mail order? Quite a few big businesses have been built in the last few years doing this—JS&A, the Sharper Image, Markline, and so forth. The best time to see the smaller Asian firms is in October during a series of consumer electronics shows.

These shows are set up so you can attend four of them in the four key Asian electronics manufacturing countries—Japan, Korea, Taiwan, and Hong Kong—one after the other, all in two weeks. This could be two weeks which might change your life—if you have some entrepreneurial spirit.

Commerce Tours has been arranging trips to Asia which bring people to these four shows for several years now. I've been going on them for five years and have been very impressed by the fine hotels, the number of special events and meals, and the planning of every detail by the firm. And the price—I don't see how they provide so much so reasonably.

I've encouraged hams to accompany me on these trips in the past and every one of them has had a great time—often meeting with Tim Chen BV2A in Taipei, shopping for electronic equipment in Hong Kong at incredibly low prices (I have my shopping list already made out), loading up on dirt-cheap Apple boards, and so on.

The tour is timed to get you to all four of the shows, complete with all transportation. This is about the only real way for you to meet and talk business with the hundreds upon hundreds of small manufacturers in Asia. This is where you may find some brand-new products which haven't yet migrated to the US—or perhaps some lower-cost versions of popular items.

The whole trip costs $2,000. That includes all transportation, first-class hotels, lavish breakfasts, a number of other meals, show admissions, several optional shopping tours, and so on. Bob Chang and his family, who organize electronics and computer tours, are at home in Asia and thus have everything under superb control.

We've always had a group of hams on these tours, which usually run from 150 to 250 in number. This year we're going to be joined by a group of Australian amateurs, so we should have even more fun. And wait until you see the price of Japanese ham rigs in Hong Kong!

The trip leaves California October 2 and returns October 16. You can leave from either San Francisco or Los Angeles. Further, if you want to take some extra time at the end of the tour, you can come back for a small additional fare any number of ways. I've made low-cost side trips to China, Macao, down to Borneo, stopping off at Sarawak, Brunei, Sabah, and Manila, or via Bangkok and Singapore, Hawaii, and so on. Why not add a couple unusual shopping stops and visit some rare DX hams? They'll love it and so will you.

Please let me know as soon as you can if you are planning to join me this year. But watch out, I'll be looking for things to import, too. Drop me a line for details: Wayne Green—Asia!, *73*, Peterborough NH 03458.

Operating? Japan is still tough, but we might be able to make it in Korea if you ask ahead. Taiwan is still tight. Hong Kong is a song—just bring a copy of your license. Yep, they have two-meter repeaters there.

73 INTERNATIONAL

from page 96

DX from 7:00 am to 9:00 am at first, and then later perhaps for another hour. Later, it is expected that there will be a new repeater for the 10m-FM band (which I understand has already been purchased) so that daily DX contacts can be made continuously, especially with friends in the United States. Question: Would you be able to recommend a frequency that we could set our repeater on for 10m-FM use? If so, please contact me immediately with the information and I will have it relayed to the proper authorities. We need to have an idea of a frequency that would be preferred to our fellow hams in the USA as well.

REPEATERS IN MEXICO CITY

As you may know, Mexico City is said to be the largest city in the world (population-wise). Some have said that there are more than 16 million people (taking into account the metropolitan area as well as the surrounding areas that are practically part of the city itself). Well, if you come to visit us someday, you'll know what I mean! Better freeways and overpasses are constantly being constructed, adapted, and changed. To illustrate the point, I was driving along with my father-in-law one day (he's a native from Mexico City). Well, we got lost for about 2½ hours! So you can imagine what it's like, even when you think you know what you're doing! (Unfortunately we did not have our 2-meter equipment with us at the time. Last time I'll make that mistake!)

So, where you have a big city, you have a larger ham population as well, and even a few repeaters and radio clubs who own them. (See Fig. 1 for a list of clubs and their repeaters in Mexico City.) Of course, you have to be authorized by the Mexican Communications Department in order to use your equipment here in Mexico. Be sure your papers are in order before vacation time unless you just want to go "all ears." The local operators here are very friendly and sociable and enjoy having foreign visitors drop in. And it's nice also if they have personally been in contact (QSO) with you beforehand, which makes it all that more interesting.

With most radio clubs that I have known in different parts of the country, it's a custom to get a few of the members together for a cup of coffee and maybe a small meal (tacos anyone?) whenever foreign colleagues show up. It's a real social occasion and sometimes very interesting. At one celebration that the Satellite Radio Club sponsored, Marciano XE1GIY flew his jet overhead a couple of times as we made contact on two meters with him before his departure. I'm sure you'd enjoy good-old Mexican hospitality! And your friends would enjoy sharing it with you!

THE VRZA

This month I would like to write something about the VRZA (the Vereniging van Radio Zendamateurs). As you may already know, there are three amateur-radio societies in Holland and one of them is the VRZA. Translated into English, these letters stand for Union of Ham Radio Amateurs.

The VRZA was founded in 1951, about 33 years ago. The number of members is enormous for a small country like ours. As far as I know, they have 4500 members, but by the time you read this the number will no doubt be much higher. Well, as you see, amateur radio is a fast-growing style of life in Holland.

The VRZA has also its own magazine which is sent out to members once a week. It is full of news and technical articles concerning ham radio. Many of the build-it-yourself projects that are published in this magazine (called *CQ-PA*) are from VRZA members. Often the VRZA has circuit boards available for these build-it-yourself projects, for cost price. Another service is the selling of hard-to-come-by parts, such as special coils, filters, transistors, etc.

PA0VRZ/A is the callsign of the VRZA club station. This station is on the air every Saturday morning on the 80- and 2-meter bands with news on phone, CW, and RTTY. Also a code course is given.

AWARDS

Although the VRZA has a large number of awards, there is one that deserves special attention, namely the WAP Award (Worked All Provinces). This award is available to hams who have worked all Dutch provinces or to SWLs who have received amateur stations from all provinces. For those who wish to know more about VRZA awards or about the VRZA itself, I'll give you the address: VRZA, Postbus 61420, 2506 Ak Den Haag, The Netherlands.

Don't forget some IRCs to cover the expense of answering and mailing your letter.

DUTCH QRP ACTIVITY

For the QRP enthusiast in Belgium, Holland, and Luxembourg, we have the Benelux QRP club (BQC). This club is especially for amateurs who like to work with low power. An output of 5 Watts for CW and 13.4 Watts for SSB is the maximum power that can be considered as QRP.

The Benelux QRP club gives advice to its members, organizes QRP contests, and has its own low-power network every Saturday morning at 0930 UTC. Members of the club use the international QRP frequencies: 3,560, 3,690, 7,030, 21,060, 21,285, 28,060, and 28,885 MHz. The BQC is also a member of the World QRP Federation. The address of the BQC is: PO Box 15, 2100 Heemstede, The Netherlands.

NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

As this column is being prepared during December, while our northern-hemisphere confreres are celebrating the Christmas festive season in true form with the traditional winter scenes and trappings, we here down under celebrate under somewhat different conditions. There is no snow, and a large part of the populace heads for beach and lakeside resorts to celebrate Christmas in temperatures of 20° C plus, depending upon the location.

But no matter where we are in the world, as far as seasons are concerned, Christmas will always consist of a Christmas tree trimmed with lights and artificial snow, Santa Claus in his heavy red uniform, complete with white beard and hat (always a very hot job), with his sleigh full of presents for all, and a huge dinner on Christmas day of roast turkey, chicken, pork, or lamb (depending upon choice) plus vegetables, followed by Christmas plum pudding and complemented with the usual beverages.

Although it is somewhat out of season for us here in ZL-land to have a huge hot midday meal when the weather would indicate a cold-cuts-and-salad-type meal, followed by cold sweets, most New Zealand families still stick to the traditional dinner and celebrations, following the traditions of our forebears who, in most cases, came from the northern hemisphere. Christmas in ZL is also the main holiday season, most of the commercial concerns closing from Christmas Eve until about January 10th for their annual holiday, with the exception of small staffs to handle urgent business. The retail section of the business community goes on as usual, although almost everything closes down completely on Christmas Day.

BITS 'N' PIECES

Recently NZART obtained permission for radio amateurs to play chess against other radio amateurs on the air. This is another step in the expanding international group: Chess Amateur Radio International (CARI), whose headquarters are at PO Box 682, Cologne NJ 08213, USA. This group is encouraging participation in on-air chess games between radio amateurs, and the group has interested members from W, VE, HH, I, OH, VK, ZL, DA, KH6, and KL7. Write to the address stated for further information.

The first CARI Oceania tournament was held in August, 1983, with stations from KH6, VK, and ZL participating. Now in its second year, CARI has 160 members, has regular weekly and daily schedules, and a special "contact wheel" for finding chess QSOs. A rating system has been established and regional tournament directors appointed in seven areas worldwide. The founder and first president of CARI is Vince Luciani K2VJ. It is interesting to note that amateurs in New Zealand were playing chess over the air prior to 1932, and an article in *Break-In*, the NZART official journal, in August, 1932, covered the activity. In the intervening years, the activity went into recess until it was revived by the formation of CARI.

Morse code is alive and well—so goes a report from ZL4FC in *Break-In* on the use of Morse code in commercial communications, particularly marine communications, here in ZL. There are still professional brass pounders here, employed by the New Zealand Post Office at three of the four Marine Coast Stations operated by the NZPO, and many of them are amateur-radio operators, too. Morse is the main mode of long-distance high-frequency communication and still proves reliable when all else fails.

Morse is the main mode of communications at Awarua Radio, situated at the southern end of the South Island and, to a lesser extent, at Auckland and Wellington Radio Stations. The New Zealand Post Office still trains operators at their school in Wellington, where the trainees have to attain proficiency in the code at 25 wpm both sending and receiving, over a 10-minute test period, with only two errors allowed. This high standard of proficiency in Morse has been unchanged since the days of the telegraph landline circuits, when the Post Office employed hundreds of Morse operators on circuits throughout the country.

Morse is on the decline in the commercial communications area, with the inroads made into Morse traffic by Telex (SITOR) and satellite traffic, but the biggest impact on marine traffic has been the decline in the number of ships now in world fleets. Two vessels now do the job of 10 ships since the concept of carrying cargo in containers was introduced, and this has had more impact on Morse traffic than anything else. But as the writer of the *Break-In* article says, "Morse is alive and well, and the skills of the brain and fingers of the Morse operator still play a part in modern technology."

The historic space-shuttle flight of Owen Garriott W5LFL during the latter part of November was followed with great interest in ZL, but as far as can be ascertained to the date of this writing, no ZL was able to record a QSO with W5LFL, and I don't think any ZL was successful in copying him, either. But I am awaiting confirmation of this from the VHF and satellite experts elsewhere in the country.

An extract from a lecture sponsored by the Auckland University Foundation, given by the distinguished space scientist and ZL, Sir William Pickering, congratulated New Zealand communications engineers on the development of a hand-held radiometer, produced as a joint venture by the government Department of Scientific and Industrial Research and an Auckland electronics firm, Delphi Industries. It proved that local New Zealand industry and engineers are capable of competing with the world's best. The newly developed radiometer is to be tested on a forthcoming space-shuttle flight.

In a recent issue of one of the popular US amateur magazines, I noted in the DX column that some concern was expressed by a prominent DXer about the Kermadec Islands and the possibility of them being the likely subject of a DXpedition in the

near future. I was somewhat dismayed to read this report when there is at present a resident amateur on Raoul Island at the weather station who was active for short periods during the latter part of 1983 and who intends to be more active during 1984. He is Warwick ZL3AFH/ZL8AFH (new callsign of the Kermadecs), and according to my information, after the settling-in period just before Christmas, he was to get antennas up and be as active as his duties permit on most bands during 1984. *(Editor's note: See the Australia column, this issue.)*

The Rose City NZART Conference will be held in Palmerston North from June 1 to 4, 1984. Details of the conference venue are as follows: The Rose City Conference will be held at the Awapuni Racecourse and will commence with a reception, registration, and a wine and cheese evening on Friday night. The formal business of the NZART will be conducted on Saturday, followed by the Grand Dinner and Dance in the evening. On Sunday, the AREC, OTC, WARO, and other meetings will take place, as well as other activities including the transmitter hunt (fox hunt) and a mobile rally. An informal social and prize-giving session will conclude Sunday's activities. Enquiries for accommodation, etc., to PO Box 1718, Palmerston North, as soon as possible.

NEZCHEQ 83, the second biannual North American/New Zealand County Hunters Eyeball QSO Party mentioned in a previous column was a great success. It was held over the US Labor Day weekend at Shelton, 50 miles west of Seattle, Washington, and finished with a banquet at the Alderbrook Resort Hotel on Sunday night. In all, 17 ZL hams and YLs were amongst the 40 US and ZLs at the QSO Party. In the US group were some from as far away as Oklahoma and Alaska. The weekend activities were mainly social with a little "hamming" at the official County Hunters station and plenty of eyeballing with those so often heard and worked on 10 and 15 meters. The festivities were continuous fun from dswn until almost dawn.

It is reported that one station which worked the Convention station said he believed that the whole gathering was in the state of intoxication, but he was informed that no, the station was in the State of Washington. At the banquet, after the obligatory short speeches, the fun climaxed with awards presentations. Special awards were made to Jsy W7KBC, the first-ever North American County Hunters W7KBC Award, in honor of Jay being the first North American amateur to work all 112 New Zealand counties for the NZART Counties Award.

A special gift was made by the attending ZLs to the host, Tom KB7MT, and all other members present exchanged souvenirs and gifts. The next convention (NEZCHEQ 85) will be in Houston, Texas, and most of the ZLs and North Americans present at the 1983 convention plan to be present again.

Another member of the Old Timers Club has joined that elite band of 60-year Jubilee Certificate holders. He is Frank Bell ZL4AA, the first licensed amateur in ZL, who received his license in January, 1923. Frank is a life member of the OTC and is its Immediate Past Patron. 50-year certificates have also been issued to J. (Rollo) Schofield ZL1JK, Arthur Allen ZL1JQ, and Arthur Lyes ZL3JD.

Silent Keys recorded recently were John Palmer ZL1KV, Norman Walding ZL2GZ, Sam Hopkins ZL2AGX, Stan French ZL2JB, and Eric Pool ZL2MZ.

SCOUT RADIO AMATEURS

Scout radio club activity was suspended after martial law was declared in Poland, but even before a reinstatement of individual ham activity, 30 Scout radio clubs got licenses. Two contests, "Scout's Wave" and "Silesia-Polish Scouts' Association," were organized this year. Among individual stations, the other contest was won by SP9EMI. The best club station was SP7KTE, and the best monitor was SP7-8801/K. Regularly on Mondays and Fridays at 1700 GMT on 3700 kHz, the so-called Scouts' Circles take place. An exchange of training radio telegrams on 3550 kHz CW on Mondays, Wednesdays, Thursdays, and Saturdays, and on 3700 kHz SSB on Tuesdays and Fridays begins, always at 1600 GMT.

Scout radio stations working on 3.5 MHz revived the activity of Polish hams this summer. Many young hams in Scout uniforms practiced their skills in camps competing for the certificate, "Scout's Camps." One of these camps was organized by the Communication Committee of the Polish Scouts Association (PSA) together with the Konin Troop of PSA in Mikorzyn, near Konin. 15 Scouts and 2 instructors from the Korin, Leszno, and Poznan troops were to take part in a school of Scout communication and amateur-radio location. Finally, 49 participants for the communications course and 10 candidates for referees of amateur-radio location gathered in this beautiful spot.

Participants at the Mikorzyn camp were taught all kinds of Scout walking, telephone, and radio communication. Shortwave instructions, treated at this camp as an introduction, will be continued at a winter camp in Kiekrz. Instructors were confronted with the problem of teaching communications courses to budding novices of the communication art, 13 to 18 years old. In spite of nearly 10 compulsory lessons daily, these Scouts elected to have supplementary sessions. Radio station SP3ZCU/3 was establishing contacts during the time of the camp. Films on principles of electrical engineering and electronics rounded out theoretical and practical courses.

A final session took place on August 8th. Candidates for referees of amateur-radio location prepared and carried out the final contest on 3.5 MHz and 144 MHz by themselves. Other participants at the school acted as competitors and proved their skills before the coming Radiolocation Contest of Poland. Skilled staff and the lovely neighborhood of Slesinskie Lake contributed to a nice atmosphere at the camp. Many Polish and foreign visitors (these last from Germany and Bulgaria) went and saw their friends.

Some months ago I mentioned the SPDX Contest 1983 that was doubtful then. Among individual stations taking part in this contest were SP7AW, leading with 809 points and 232 certificates, SP9DH (573 and 138), and SP9ADU (557 and 182). The best club station of the contest was SP7KTE (660 and 201), and among monitoring stations, SP9-3354-KA (132 and 40).

Sweden

SSA ANNUAL MEETING

The Swedish amateur radio league, SSA, is holding its annual membership meeting this year in the city of Falun in the province of Dalarna (Dalecarlia). The meeting is taking place during the weekend of April 14-15. The hosting Falu Radioclub is celebrating its 60th anniversary.

The province of Dalarna has played an important role in Swedish history. The farmers were willing to fight for their freedom and, among other kings, Gustav Wasa managed to get them to uprise against the Danish intruders in 1521. To celebrate this, every year over 10,000 skiers compete in the world's oldest and largest cross-country ski race from Salen to Mora, a distance of close to 90 kilometers (65 miles). Besides the regular meeting on Sunday, there will be exhibitions, speakers, women's activities, and the Saturday night banquet. Dalarna is in the SM4 call area.

PACKET RADIO

The Softnet User Group at the University of Linkoping is inviting everybody interested in experimental packet radio for both ground and satellite systems to EXPRAN 84, this year's Softnet workshop.

The Experimental Packet Radio Network Symposium is taking place in the city of Linkoping (SM5 call area) on May 26 and 27, 1984. Planned subjects for seminars are packet radio, network control and routing, distributed processing, proposals for standards, and Softnet. The Swedish high-technology aeroplane and computer industry, SAAB, is located in Linkoping.

TELEPHONE INTERFERENCE

Televerket is the National Swedish Telecommunications Administration and has the monopoly for telephone communications distribution in Sweden as well as being the licensing authority for radio communications. Televerket is also a manufacturer of telecommunications equipment as wall as the approving authority for equipment manufactured by others that is designed to be connected to their systems.

Only a couple of years ago the telephone system in Sweden allowed modem push-button telephones. These have, of course, turned out to become very popular and are replacing the old rotary-dial phones. Televerket manufactures a push-button phone called Diavox, about the only one, for the time being, approved for their own system, i.e., the only system in Sweden.

These new telephones made by Televerket and spreading very rapidly are of great concern to us active radio amateurs. The Diavox telephone is extremely susceptible to rf. Televerket is now very well aware of this fact and is trying to take care of problems when interference complaints are filed. Before then, however, the innocent ham operator has had another confrontation with his neighbors. Everyone that has had such an experience can tell that there are more pleasant meetings than these. I had one fellow from Televerket working on my Diavox telephone for 2½ hours without complete success. The interference was there either when operating on 14 MHz or 28 MHz. Considering the low sunspot cycle we are in now, I chose to have the interference on 28 MHz!

It is very unfortunate to have this unnecessary interference problem, especially now with the growing popularity of video recorders that may become our worst RFI problem to date. The video recorders seem to be more susceptible to rf than any of the other home electronic equipment we have fought so far.

WINTER CONDITIONS

In this arctic region, aurora borealis is very common during the winter season. This dark time of the year favors the low-band DXers propagationwise. It is even possible to work the 160-meter band 24 hours a day during several weeks around Christmas.

As a rule, you can say that "the closer to the equator you are, the better short-wave propagation you have." Being a DXer, living this far north as we Scandinavians do is sometimes tough. About the only time we have a more favorable situation than the south Europeans is when propagation to the Pacific is over the North Pole. This is common during early morning local time in the summer.

During the deep winter season, our most stable DX band, 20 meters, closes down completely in the evening around 1800 hours and opens up when it is time to leave for work in the morning. If you do not like the very noisy low bands, there is not much hamming to do these dark winter nights. It is hard for non-Europeans to imagine how crowded the low bands are here at night. The broadcast and other commercial intruders on the 40-meter band that you may be bothered with are much stronger here than anywhere else!

RECEIVER SHORTCOMINGS

In the late 60s and early 70s, many hams here lost interest in the 40-meter band. I think this was primarily because of the cross-modulation problems the new transistorized receivers were impaired by. One major importer of Japanese ham equipment once told me that he could not convince the manufacturer how severe this problem was here is Europe until they got to experience this on the spot. The receivers certainly have improved in this respect, but the intruders are still pounding their hundreds of kilowatts within the ham-exclusive 100 kHz of the 40-meter band.

80 METERS SHARED

The 80-meter band is shared with other services in Region 1. In the evening it is hard to find a spot where the S-meter drops below the S9 level. With good antennas, sharp filters, and a great deal of stamina, some avid DXers manage to break through the noise level and to work distant stations even on eighty.

AURORA AND TWENTY METERS

When there is aurora, which happens quite often, the 2-meter buffs are happy. However, it also favors very short skip QSOs on 20 meters. Normally, you cannot work within Scandinavia on twenty, but in aurora conditions LA, SM, OH, and UA1 are workable. Very seldom we can reach as far south as OZ Denmark. In aurora a totally dead band suddenly becomes alive.

STRANGE OPENINGS FROM LAPLAND

I grew up in Lapland, northern Sweden, just north of the Arctic Circle, which is the call area SM2. My QTH was located further north than Fairbanks in Alaska, which might be of some reference help to

you. In the wintertime from up there I usually could work the west coast of the North American continent at night. VE8, VE7, KL7, W7, and all the way down to W6 was (and, of course, still is) workable. The signals crossing the North Pole are characterized by a very rapid flutter. In those openings you may not hear too many stations from here. The reason is simple. The population is small in those arctic areas of Sweden, Norway, Finland, and the Soviet Union.

Now summer is quickly approaching. The conditions are changing. With the midnight sun and daylight 24 hours a day, the change is not entirely to the better, but it surely is different!

John L. Webster 9Y4JW/8P6KX.

TRINIDAD AND TOBAGO

John L. Webster 9Y4JW
c/o Department of Soil Science
University of the West Indies
St. Augustine
Trinidad
West Indies

The Trinidad and Tobago Amateur Radio Society (TTARS), formed in 1951 and incorporated by an Act of Parliament 30 years later in 1981, has a membership of 140, from a total population of 1.2 million persons on the two islands. There are also about 100 associate members in the society. Only about fifty percent of the 140 hams are active, some on VHF, some on HF, and others on both.

The TTARS has been a member of the IARU for about 10 years and is an affiliate of the Radio Society of Great Britain (RSGB).

The British City and Guilds Radio Amateur's Examination (RAE) is the certification required by the Government of Trinidad and Tobago, along with Morse code proficiency at 13 wpm, for the issue of a 9Y license. The code test is administered by the Director of Telecommunications after the successful completion of the RAE exam. In 1982, the TTARS stepped up its training program in an effort to encourage more persons to become hams, and weekly classes are conducted to prepare its associate members for both.

Unfortunately, the exam is offered only once a year as it is an external examination. It is written in May and the results are not known until the end of August or about three months later! The successful candidate then applies for the code test.

The 1982/83 training classes were conducted at two centers, one in the north of the island, in the captial city of Port of-Spain, and the other in the south, in San Fernando, the industrial center. There is now a third center for the 1983/84 classes, in the center of the island, at Chaguanas.

At each center, classes are conducted twice weekly, one session for theory and the other for CW.

The TTARS normally charges a small fee, the main objective being to encourage those who started the course to complete it. Any funds raised in this way are available to assist in acquiring equipment and materials needed in running the course. However, as 1983 was World Communications Year, the TTARS decided on an "open-house" policy for the 1983/84 training classes and there is no charge for the course this time.

Good results have been achieved by the TTARS in the RAE examinations. In the 1982/83 examination, 90 percent of the candidates prepared by the TTARS were successful. In actual numbers this means that there are 22 potential new 9Y hams if they complete their code tests. One of the successful candidates, Mark Massiah, obtained a double distinction in the exam and provided a very good showing in his code test. Mark, who has been assigned the callsign 9Y4M, favors CW operating and should be providing a new country to many of you still needing 9Y on this mode.

The TTARS does not have a clubhouse but is allowed the use of Boy Scout Headquarters in Cascade, north Trinidad. Meetings are held on the first Monday of each month at 7:30 pm. The meetings alternate between north and south Trinidad, those in the south being held at Presentation College in San Fernando. The Annual General Meeting, at which new officers are elected, is always held in north Trinidad during the month of March.

In my next column I will present part I of a two-part review of the activities of the TTARS during 1983, World Communications Year.

CODE OR NO CODE?

The FCC's lengthy release reporting on their turning down of the no-code proposal indicated that there was a great unanimity of thought by the hams and clubs who where interested enough to comment on this subject. Morse code must be kept as a fundamental skill for being an amateur—that was the edict. Presumably this was not merely an emotional response but a well-reasoned one—and thus one which all of us should expect to live with and honor.

There was a high degree of agreement that when the chips are down—perhaps referring to EMP and its destructive effect on ICs—CW can always get through. Well, heck, yes, if we have a key at hand to send CW. But more and more rigs are being made without even a key jack! I'd say that in view of this statement of amateur sentiments, we should quickly bring a halt to that and make sure that every new rig has a key jack.

Perhaps two out of three of the transceivers being sold these days are for VHF and designed for phone-only operation. Obviously we are contributing to serious future problems by moving away from the code in this way. I suggest that our first response to this unanimity on the code be to put pressure on the manufacturers not only to put a key jack on every hand transceiver, but to insist that they build a small key right into them and include a tone modulator.

If you remind the manufacturers that you are serious about Morse code—that you really believe it is important (you were being truthful in your comments to the FCC, right?)—they'll have to build CW into their rigs. And if they don't respond, I might follow up with a proposal to the FCC to make it illegal to sell a transmitter without a key jack. All hand rigs should have the complete key built in, obviously, since there is no practical way to hold the rig in one hand, the key in the other, and then try to send.

It will be easy to build a small paddle key into our HTs. With that you will be able to send with one paddle as a straight key or with both as a speed key. And, of course, speed is the only way to go for emergency communications.

Speed. Hmmm. That brings up a major problem. With CW now recognized by the FCC via your comments on the no-code proposal as being of far more importance than previously thought, we have a grave responsibility. When The Chips Are Down (WTCAD) and hams are the only means of communications in an emergency—and we have to use CW—code speed is going to be of incalculable importance. Even relatively small emergencies seem to generate enormous amounts of message traffic, so we will be in one hell of a mess if some turkey in the chain that we are depending on can't handle the code at a reasonable speed. One lazy jerk could bog everything down, bringing discredit to our entire fraternity.

Well, then, granted that your comments are right and CW is our number one means of communications, what code speed should we accept as adequate? In the commercial world, back when they used the code instead of digital communications a couple generations ago, 35 words per minute was the accepted code speed. That was average. Is there any reason why we should be any less than average? Of course not. We should be better than the old average commercial ops, right?

This means that we really

To enter your QSL, put it in an envelope along with your choice of a book from *73*'s Radio Bookshop and mail it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries not in envelopes or without a book choice will not be accepted.

From Base to Beams

Home-brew from the ground up! Here's how to build a tower and top it off with performance-proven antennas.

Harry D. Hooton W6TYH
1420 Shamrock Lane
Lincoln CA 95648

During my 53 years as a licensed radio amateur, I have owned a number of masts and towers ranging from the old-time A-frame wooden mast to a modern 80-foot commercial steel tower. At the age of three score and ten plus two, I am no longer enthusiastic about climbing and working on top of a high tower of standard design and construction.

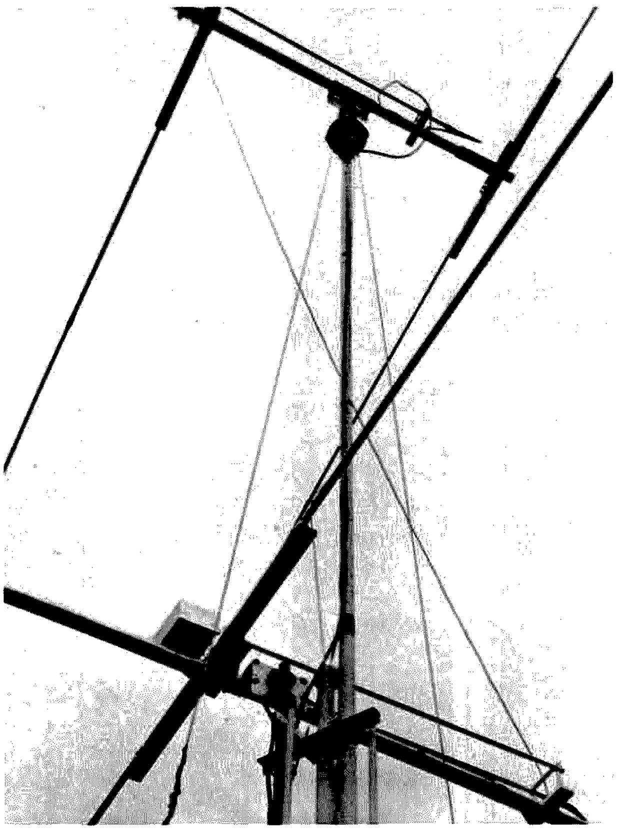

Photo A. The two monobander arrays mounted on the tower. The upper array is a 2-element, 15-meter yagi using a line-bazooka matching system. The 15-meter array is rotatable over 360 degrees. The 10-meter, 3-element yagi also used a modified line-bazooka matching system. The 10-meter array is rotatable over a 60-degree arc. The 10-meter array is used strictly for communication with the South Pacific area, VK, ZL, etc.

Since 1978, I have been experimenting with multi-mode arrays, some of which are physically large and electrically complex. These antenna systems require many measurements and adjustments necessitating removal of the array from the tower and reinstalling it after the adjustments or changes are completed. To further complicate matters, W6TYH is located in the country, far away from other hams. Most non-ham neighbors are less than enthusiastic when it comes to raising and lowering the usual amateur array that goes up or down perhaps once a year. When an array must be raised, lowered, and raised again every day over a period of perhaps two weeks, helping-hand neighbors or friends are conspicuous by their absence. Long ago, I found that the dyed-in-the-wool antenna experimenter is regarded by his neighbors (and by some fellow hams) as a kind of nutty individual to be avoided at all times when arrays are to be installed or removed from the tower.

Obviously, what is needed is an antenna support structure that can be easily installed at minimum cost and will permit one man to install or remove arrays safely and easily. The tower to be described is designed to fulfill these requirements.

Tower Design and Construction

The multi-mode array, because of its large size, requires a strong tower. Also, the tower, if possible, should be made free-standing since guys and other support devices make the raising or lowering of an array difficult. When matching or phasing adjustments are made, it is essential that the array be at least 15 to 20 feet above the ground. Otherwise, there will be an excessive amount of "cut and try," resulting in much labor and a waste of time. In the interests of economy, it is desirable to design the tower so that readily available accessories such as extension ladders, hoists, etc., can be used when required. All of the materials should be available locally; scrap or surplus iron pipe and angle-iron cross members can be used. The tower can be constructed without welding or brazing techniques (usually

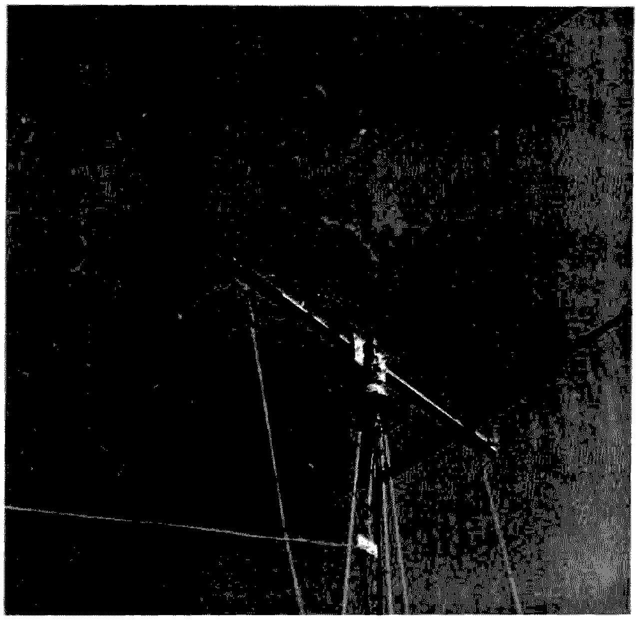

Photo B. *The tower top section showing the rotator and the 15-meter array. The matching stub, made from two copper tubes, is mounted on insulators above the boom. Note the ⅜-inch stabilizing ropes attached to the bottom of the rotator unit. Also note the trailing ⅜-inch nylon ropes attached to the ends of the boom. These are used to secure the array during windstorms. This tower and array have survived winds of over 60 mph. The tower also supports a 40-meter inverted-V dipole.*

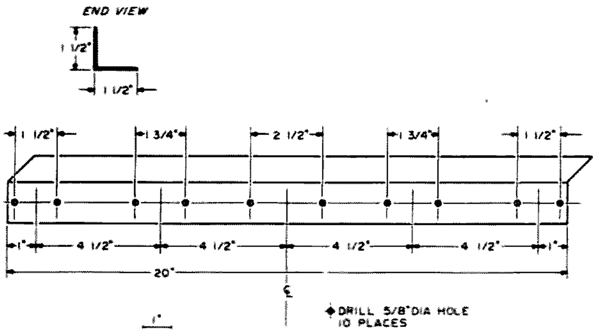

Fig. 1. Cross-member dimensions. Sixteen pieces of angle iron required—1½" wide each side.

not available to the average ham).

As shown in the photos and drawings, the tower is constructed as a cage of four ½-inch-diameter iron pipes arranged around a 1¾-inch central pipe core. The tower shown here is made up from black, non-galvanized iron pipe which was obtained from a scrap-metal dealer. To prevent rusting out with time, the black iron pipe must be painted, first with a primer coat and then with two coats of implement enamel. If you use galvanized pipe, it is not necessary to paint the tower unless this is desirable for aesthetic purposes. The four ½-inch pipes are firmly attached, by means of angle-iron cross members and U-bolts, to the large-diameter center pipe. The center pipe extends upward 20 feet above the ground. The ½-inch pipe is manufactured in 21-foot lengths. For ease in handling, each 21-foot length is cut into two 10-foot, 6-inch lengths. The shorter lengths are threaded at each end so that two or more sections can be connected together with standard ½-inch pipe couplings. The tower is extended upward by adding the 10-foot, 6-inch lengths to the desired height. Although the cage structure of this particular tower extends upward only 20 feet, it should be possible to construct a free-standing tower to a height of at least 35 to 40 feet above the ground.

If a higher cage structure is desired, the use of appropriate guys is recommended. With a 20-foot-high cage, an array can be raised to about 35 feet above the ground. With a 40-foot-high cage, an array can be raised to at least 50 to 55 feet above the ground provided, of course, that the tower structure is properly guyed. The 20-foot cage height was selected so that a standard 20-foot aluminum extension ladder can be placed against the tower, making it easier to climb.

The array is mounted on the top of a 21-foot-long, 1½-inch iron pipe placed vertically against the cage section. By means of winch and ratchet, this pipe can be extended about 16 to 18 feet above the top of the cage section for a total height of about 36 to 38 feet. This feature will be described in more detail later. The angle-iron cross members are spaced at about 2½-foot intervals up the central pipe. The tower is erected in exactly the same manner as that of a commercial radio- or TV-station tower—by adding on sections until the desired height is obtained.

Tower Installation

First, select a suitable site for the tower. If you expect to be taking arrays up and down the tower frequently, do not erect the tower against the side of a building. Make certain that the array, when mounted on the tower, can rotate freely without coming near other antennas, trees, power lines, metal roofs, or buildings. Trees and other non-metallic objects will have no effect, for all practical purposes, on the tuning or operation of an array, provided that the element tips do not approach closer than 15 or 20 feet during operation. If the array is mounted within 20 to 25 feet of a metallic object, such as a metal roof or power line, the line swr will usually vary as the array is rotated. Arrays mounted close to any object, metallic or not, are often noisy on reception.

Once the site is selected, dig a hole in the ground as shown in Fig. 2. The hole should be about 18 inches across. The depth will depend upon the type of soil at the selected site. For clay or similar hard-packed soils, a depth of about 4 feet will be sufficient. If the soil is sandy or gravelly in nature, the hole should be made deeper, to perhaps 5 or 6 feet. At the W6TYH antenna site, the soil is decomposed granite which packs solid in dry weather but becomes very soft during the rainy season. The hole for the tower base was dug to a depth of about 5 feet and side brace supports were added to the tower at a height of about 8 feet above the ground. The ends of the side supports (½-inch pipe) extend into the ground for about 3 feet and are held firmly in place by "deadmen" made by pouring concrete in each hole.

Fill the bottom of the hole to a depth of about 4 inches with egg-size gravel. Stand the large center pipe on its end on the gravel and guy or brace it in an upright position. Pour another 2 or 3 inches of gravel around the center pipe. This allows it to extend below the base of the concrete and also permits moisture from inside the center pipe to drain into

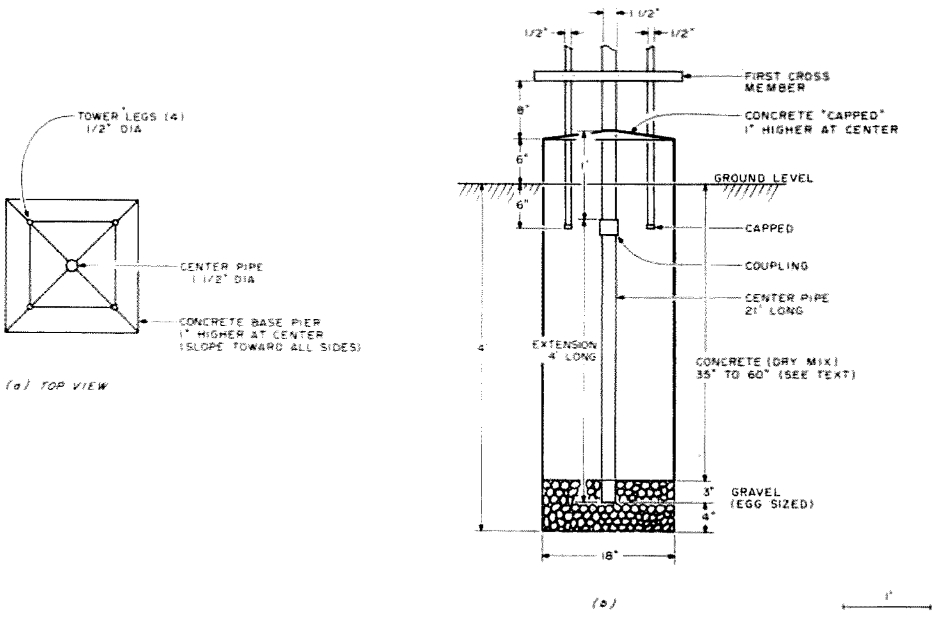

Fig. 2. Tower base.

the gravel. Before pouring the concrete mix, coat the center pipe, about 3 inches above and below the space where the top of the concrete base is to be located, with waterproof asphalt roof-patching material. Check with a carpenter's plumb and level to make sure that the center pipe is plumb before pouring the concrete, then repeat the process afterward. While plumbing the center pipe, do not pull it up into the liquid concrete or push it down into the ground. The lower two or three angle-iron cross members should be attached to the center pipe before it is placed in the hole. With the hole filled to within three or four inches below the surface of the ground, allow the concrete to "set" for about 48 hours.

After the concrete base has solidified, attach the first four ½-inch iron-pipe cage uprights as shown in Fig. 3. The bottom ends of the ½-inch pipes are capped and will extend downward about four inches below the space where the top of the concrete base will be located. It is not necessary to provide for drainage of the side pipes provided that each member is sealed by the caps at the top and bottom. When the side pipes are securely fastened to the angle-iron cross members, using the smaller U-bolts, finish pouring the concrete and crown the top of the base, as shown in Fig. 4, to prevent water from accumulating at the point where the upright

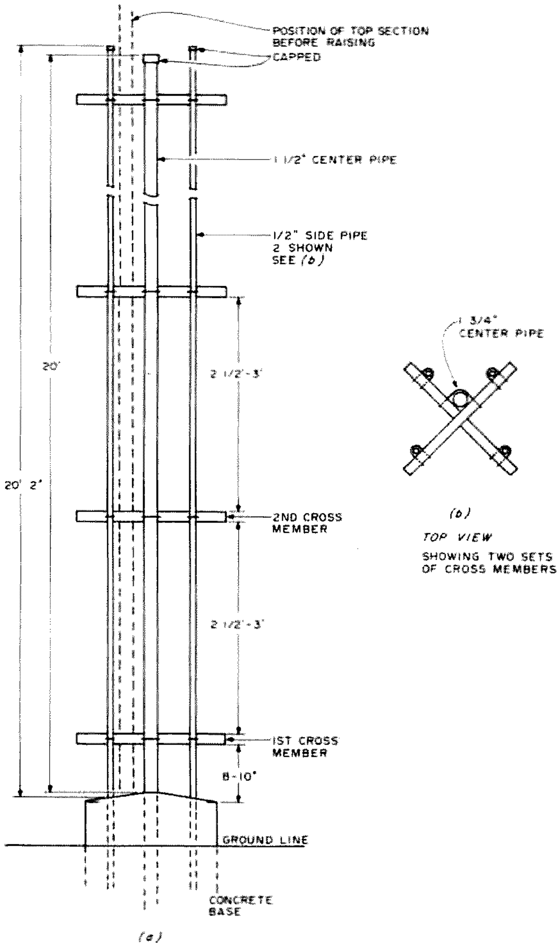

Fig. 3. How ½" pipes are attached to vertical center pipe.

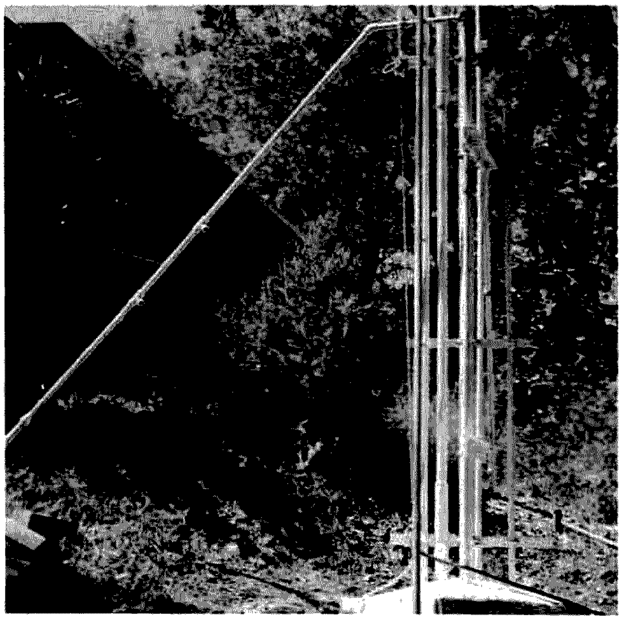

Photo C. Lower section of tower showing construction. The tower has two braces (½" pipe) attached 8 feet above ground. The lower cage section extends upward 20 feet above the concrete base.

members enter the base. Again allow the concrete base to harden for about 48 hours before assembling the remainder of the tower.

After the base section has been installed, mount the angle-iron cross members at intervals of about four feet, all the way up to the top of the center pipe, and secure the four ½-inch pipes in place with their U-bolts. The U-bolt nuts should be drawn tight so that the joint is rigidly secure.

Although this tower is sufficiently strong to be self-supporting at heights of up to 40 feet, for safety's sake, while working on the tower, it is advisable to attach at least three guys at the 20-foot level, space them around the tower 120° apart, and secure them to iron stakes driven into the ground. There is always the possibility when working on a new tower that the concrete is not completely set and the tower may fall when it is unbalanced by the weight of a man climbing it.

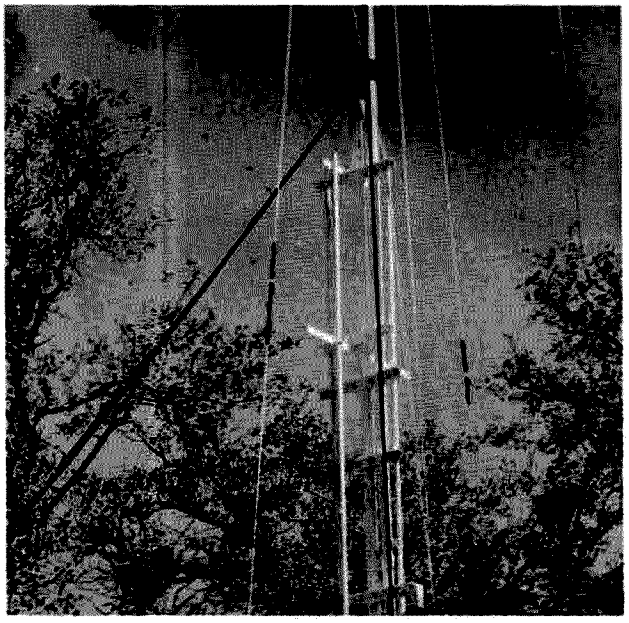

Photo D. Midsection of tower showing how top section of pipe is mounted. The top section can be extended 18 feet above the 22-foot bottom section—a total height of 40 feet. Note that the 52-Ohm coaxial cable and the rotator control cable are dressed away from the tower while the top section is being raised.

The Adjustable Upper Section

After the 20-foot cage (lower) section has been installed, the adjustable upper section, a 1½-inch-diameter, 21-foot-long iron pipe, is placed vertically against the cage section, parallel with the 1¾-inch center pipe. The lower end of the adjustable section rests on top of the concrete base. With a rope or wire, temporarily tie the 1½-inch pipe to the center pipe at the top, center, and bottom of the cage section to keep it upright. Prepare four 1¾-inch U-bolts as shown in Fig. 5. The two standoff nuts on each U-bolt will allow the U-bolt to be rigidly mounted on the angle-iron cross members and keep the 1½-inch pipe upright while permitting it to be raised.

This method is probably the simplest means of allowing the upper section to be raised or lowered while still maintaining a safe and strong mount. If the upper section is to be left permanently in the raised position, when it is in its final position, each of the 1¾-inch U-bolts is removed, one at a time, and the two standoff nuts are removed. The U-bolt is now reinserted through the two holes in the angle-iron cross member and its two remaining nuts are drawn down tightly. If the upper section is to be raised and lowered frequently, leave the U-bolts as originally installed and secure the top section as will be described later.

Depending on the height of the lower cage section (20 feet in the prototype tower), the 1½-inch pipe will extend about 1 or 2 feet above the top of the cage section. Thus, it can be reached easily from a 20-foot aluminum extension ladder placed at an angle against the side of the tower. In the photos and drawings you will notice that the last angle-iron cross member, at the top of the cage section, extends outward about 6 inches from each ½-inch side pipe. My 20-foot extension ladder is fitted with two bicycle-hanger hooks at the top. When the ladder is extended, the two hooks fit over the ends of the angle-iron cross members, keeping the ladder securely in place. The lower end of the ladder rests on the ground but is held in place by tie wires to two iron stakes driven into the ground. Since the ladder is placed against the tower at an angle, it is much easier to stand on and more comfortable than trying to hang on to the tower with one hand and work with the other. A strong web safety harness attached to the tower enables me to work in comfort and with safety.

Installation of the Rotator Unit

The array shown in the photos is a 2-element beam antenna similar to that described in the May, 1980, issue of *73*. The rotator unit used with this antenna is the CDE AR-22 which is de-

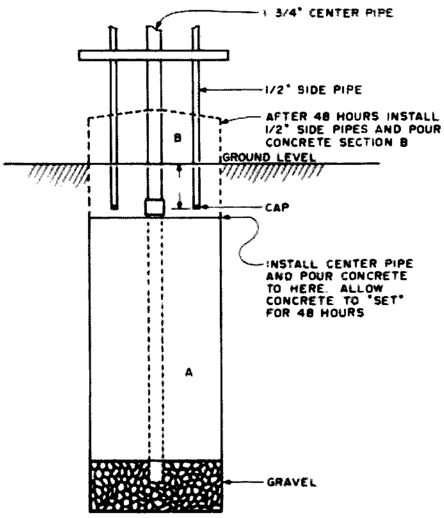

Fig 4. Second step in pouring concrete base.

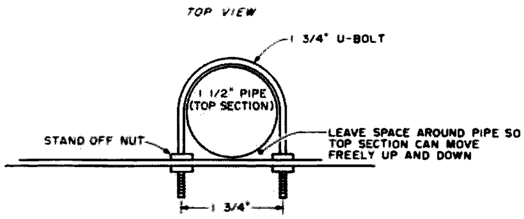

Fig. 5. U-bolts for supporting top section.

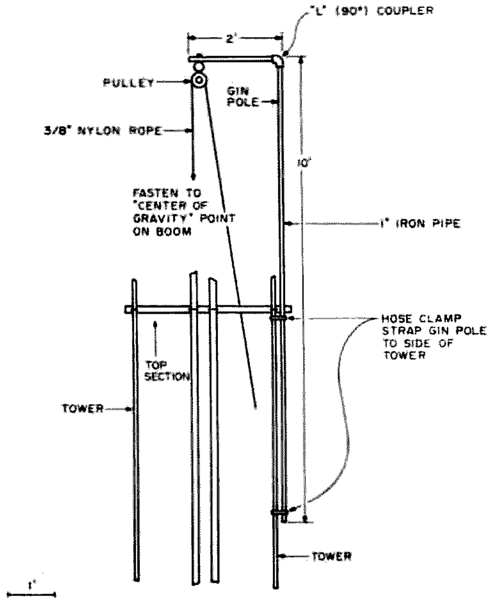

Fig. 6. Gin-pole assembly for raising array.

signed for use with large TV receiving antennas. This rotator is perfectly suitable for short-boom, 2- or 3-element beam antennas designed for operation on 10 or 15 meters. For long-boom arrays, use the Ham rotator which is designed to support and rotate a much heavier load. When the AR-22 or any similar unit is used with long-boom arrays, the up and down rocking motion of the boom in a windstorm will damage the gears of the rotator unit.

If you look closely at the photograph, you will notice a trailing ¼-inch nylon rope attached to each end of the boom. In normal use, the ropes simply hang down and rotate with the antenna. During windstorms, however, they are used to lash down the array to prevent the rocking of the boom referred to above. Two other ¼-inch nylon ropes are attached to the guying loops on the bottom edge of the rotator unit and serve to stabilize the upper section and the array during severe windstorms. Using these precautions, the tower and array have been subjected to a 70-mph wind without damage.

The 4-wire control cable should be attached to the rotator before it is installed on the tower. The terminal boards on both the rotator and control units are marked 1, 2, 3, and 4, left to right. The flat 4-wire rotor cable has one bright (tinned) conductor and three plain copper wires. The tinned (bright) lead connects to terminal 1 on both the rotor and control units. The second conductor is then connected to terminal 2, etc. If the terminal boards are wired in this manner, either unit may be disconnected and reconnected without wiring errors.

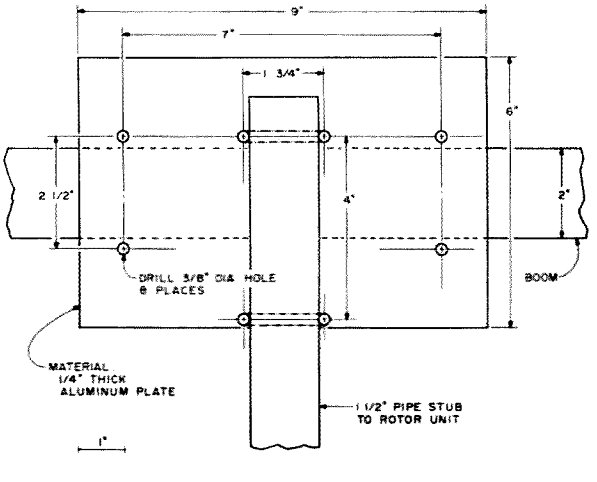

Fig. 7. Boom-to-stub mounting.

After the rotator and control units are electrically connected together, plug the control unit into the 110-V-ac source and turn the indicator pointer to NORTH. When the rotator has stopped turning, mark one side of the upper section with chalk or a spot of white paint. When the rotator is installed on the top section, turn the marked side of the unit toward the north. Tighten the mounting U-bolts until the saw teeth of the clamps bite into the metal pipe. The easiest way to lift the rotator unit to the top of the cage section is to raise it with a rope and pulley. With the safety belt or rope attached to the tower, lift the rotator unit over the top end of the 1½-inch pipe, turn the white spot toward the north, and tighten the U-bolt nuts.

Installing the Array

For an easy installation of the array, make up a gin pole as shown in Fig. 6. The 12-inch L arm has an attached rope and pulley as shown. If the array weighs 40 pounds or less, the rope can be a length of ¼-inch nylon. For heavier arrays, a ½-inch nylon rope is recommended. Make sure that you have the proper size pulley for the rope in use and that the rope runs freely through the pulley opening.

One end of the rope is tied to the center-of-gravity point on the boom. Have someone hold the other end of the rope, taking up the slack as you climb the ladder guiding the array up the tower. When you reach the top of the ladder, have the assistant pull on the rope to raise the array to a point about a foot or so above the top of the rotator. Carefully lower and guide the array mounting stub into the rotator mount. Tighten the U-bolt nuts until the teeth of the clamps firmly dig into the metal pipe stub. The boom-to-stub mounting assembly is illustrated in Fig. 7.

Raising the Top Section

After the rotator and the array are installed as outlined above, we are ready to raise the top section to maximum height. The coaxial transmission line is connected to the array feedpoint before the top section is raised. The junction of the line and the feedpoint must be wrapped with several layers of plastic tape to prevent the entry of moisture. If the coaxial line is made a multiple of a half wavelength, the swr bridge can be inserted in series with the line at *any* half-wave point and the swr or impedance value indicated will be the same as that at the array feedpoint. The coaxial line and the control cable should be dressed away from the tower while the top section is being raised. Use plenty of slack in these lines to prevent them binding or snagging on the tower cross members.

As mentioned previously, the 1½-inch pipe top section is held in the vertical position by the U-bolts acting as slip rings. If you intend to raise or lower the top section frequently, it is worthwhile to install a low-cost winch and cable assembly, such as that used on trailers for small boats, to allow the section to be cranked up or down with little effort. Since W6TYH is located on a ranch, we have available several devices

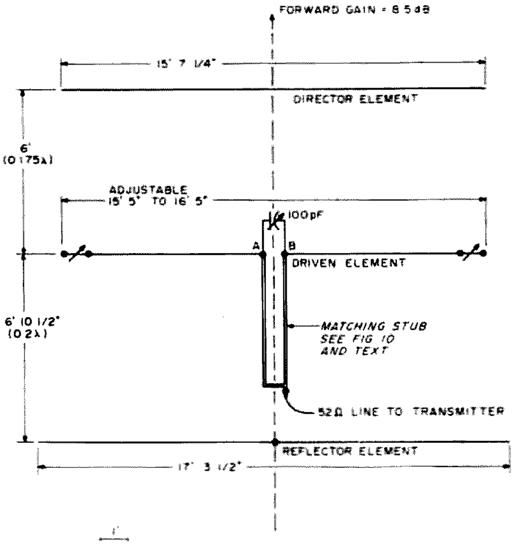

Fig. 8. Dimensions of 3-element 10-meter array.

that are useful for lifting or hoisting heavy objects such as the tower top section. The device that we used is generally referred to as a "come-along" and has a ratchet operated by a long handle. To raise a load, the handle is pumped in the same manner as that of an automobile jack. A small-size hoist that sells for about fifteen dollars at auto parts stores will lift an 800-pound load to about 20 feet.

Guys

This tower is free-standing and is not guyed in the usual sense of the term. However, a pulley with about 100 feet of ⅜-inch nylon rope is attached to the lower section of the rotator unit, primarily for the installation of a 40-meter inverted-V dipole antenna. In addition, two 60-foot, ⅜-inch nylon ropes are tied to the guying loops at the bottom of the rotator. During normal weather conditions, these ropes are simply dressed down one side of the tower and secured to the lowest cross member. During high winds, however, the ropes can be played out as guys and used to stabilize the tower. Also, you will notice that each array has a length of ⅜-inch nylon rope trailing from each end of the boom. During normal operation, these ropes simply hang down and rotate with the array. When the weather is bad, with strong winds, the trailing ropes are secured to the tower to prevent the arrays from rocking up and down which might damage the gears of the rotator unit.

The Arrays

This tower has supported many arrays during the past several years. Photo A shows the tower with the two arrays in use at present. The upper array is a 2-element, 15-meter beam antenna which was described in the May, 1980, issue of *73*. This array, the LB-2, has been in use for about 7 years and has proved to be an excellent DX antenna for both transmitting and receiving. The forward gain is 5.3 dB over a dipole under similar operating conditions. For constructional and adjustment data, refer to the article in the above-named issue.

The second array (at the lower level) is a 3-element, 10-meter array designed for maximum forward gain consistent with optimum front-to-back ratio. The forward gain is 8.5 dB over a dipole. The spacings of the elements and the element lengths, together with the dimensions of the matching system, combine to produce a perfect impedance match between the array feedpoint and the 52-Ohm coaxial transmission line. The dimensions of the 3-element array are given in Fig. 8.

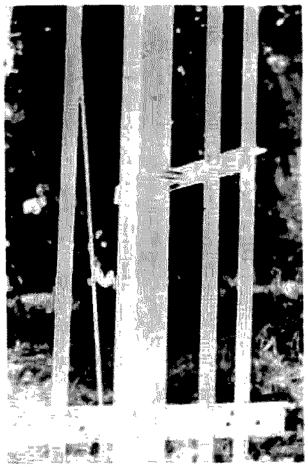

Photo E. Cross-member constructional details.

The driven and parasitic elements are made up from the popular "hobby" aluminum tubing sold at many hardware stores and building-supply houses. The center sections are 8-foot lengths of ¾-inch-diameter tubes (0.055-inch wall thickness). With the 0.055-inch wall thickness, a ⅝-inch o.d. tube will telescope snugly within the ¾-inch o.d. tube.

The inside and outside surfaces of these tubes have an oxidized finish which must be removed from the two surfaces that make electrical contact. To remove the oxidized finish from the telescoping portion of the smaller tube, sand its outside surface with 00 sandpaper and then polish it with steel wool until the surface is bright and shiny. The finish may be removed from the inside surface of the larger tube by wrapping a smaller diameter wooden dowel with a strip of sandpaper or emery cloth and moving it up and down inside the tube until the inner surface is bright and clean. Before the elements are finally assembled, the telescoping contact surfaces should be coated with an antioxidizing compound, available at most electrical-supply stores.

After the reflector and director elements are assembled and adjusted to the correct lengths, the electrical connection may be made secure by four or five self-tapping stainless-steel sheet-metal screws arranged in a spiral around the tube. After the joint is made secure electrically, wrap it with several layers of plastic tape to keep out air and moisture. If each end of each element is sealed with a wooden plug and waterproof cement, the joints will not corrode and will maintain good electrical contact for several years.

The Driven Element and Matching-Stub Adjustments

In the stub-matching system, the dimensions of the stub and the overall length of the driven element are critical. The stub acts as an inductive reactance (X_L) and the antenna is adjusted to act as a capacitive reactance (X_C). The correct combination of the two reactances will resonate the driven element at the desired frequency, 28.6 MHz in this case. The stub also acts as a balun, converting the 52-Ohm unbalanced impedance at test point A to a balanced 17- to 20-Ohm impedance at the center of the driven element. The impedance stepdown ratio (about 3 to 1) is determined by the ratio of the stub, X_L, and the antenna, X_C. With stubs of the specified dimensions, the length of the driven element, tip to tip, will be about 5 inches shorter than the length required for resonance with the common gamma match. The bandwidth of the array, each side of the center frequency, is dependent upon the correct ratio of the two reactances and the spacing of the two stub conductors. Extensive experimental work has

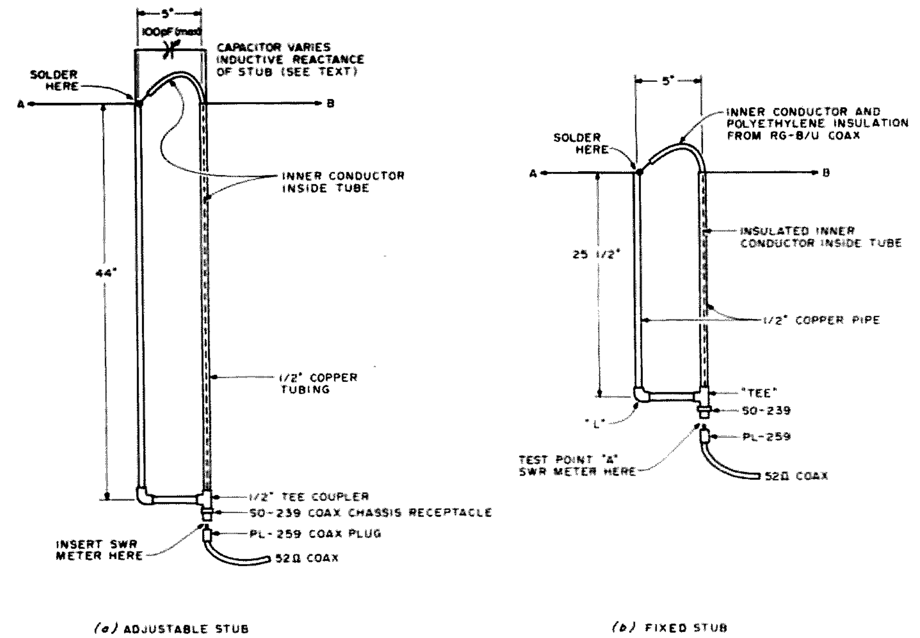

Fig. 9. Matching stubs for 10-meter array.

shown that best results on the 15-meter band are obtained with the two ½-inch tubes spaced 3½ inches, center to center. This spacing corresponds to a surge impedance of about 360 Ohms. With a shorted stub 45 inches long and spaced 3½ inches, the bandwidth of the LB-2 array is flat (1 to 1 swr) from 21.050 MHz to 21.400 MHz. At 21.0 MHz and 21.450 MHz, the swr is about 1.3 to 1. The forward gain is virtually constant across the entire 15-meter band. With the array shown in the photos, no antenna tuner or matching device is used even with solid-state output circuitry in the transmitter.

For the 10-meter array, the stub tubes are spaced 5 inches apart, center to center. Either of two stub types may be used. For the simplest possible adjustments, use the short stub with the fixed-position shorting bar. The 25½-inch length is correct for the center frequency of 28.6 MHz. For a center frequency of 28.4 MHz, the stub should be made 26 inches long. For a center frequency of 28.8 MHz, the stub length should be made 24 inches long. With this stub, it is only necessary to carefully adjust the length of each half of the driven element until a zero reflected-power indication is obtained at test point A or at any half-wave point along the transmission line away from the antenna. To maintain electrical balance in the array, each half of the driven element should be lengthened or shortened by the same amount. The electrical balance of the array can be checked by touching each end of the driven element, in turn, with a fingertip. The swr indicator deflection from zero should be the same when touching either end of the element. The electrical balance of the parasitic elements can be checked in the same manner. It will be found that the director-element tips are

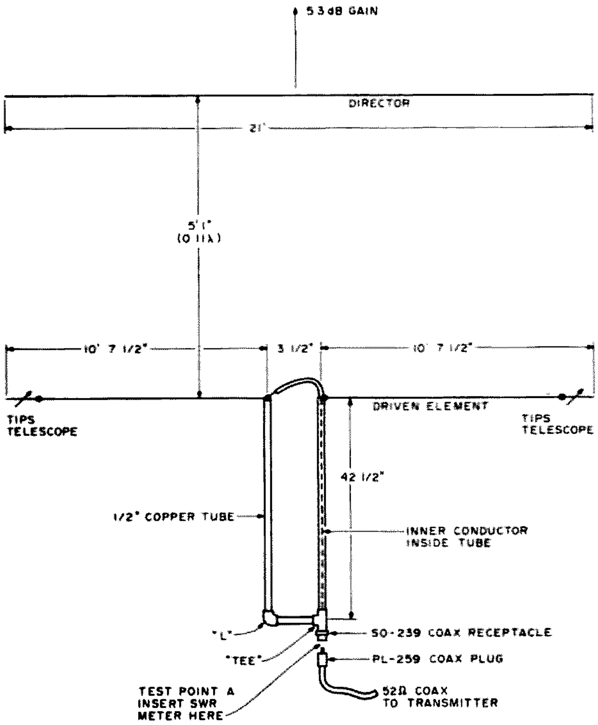

Fig. 10. 15-meter array.

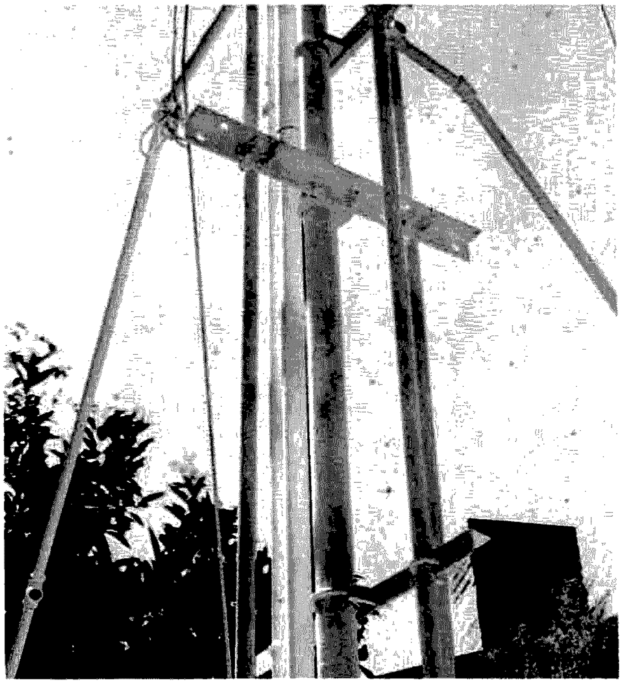

Photo F. Bracing details.

very sensitive to any conductive object while the reflector-element tips are relatively insensitive.

The long-stub conductors are each 44 inches long and spaced 5 inches apart. The stub alone has an inductance value greater than that required to match the 52-Ohm line to the balanced driven-element feedpoint. The inductance value can be reduced by shunting a 100-pF air-dielectric variable capacitor across the open end of the stub. In this application, the variable capacitor action is similar to that of an adjustable shorting bar, allowing the stub inductance to be adjusted as required.

To start the matching procedure using the long stub, adjust the variable capacitor to about one-half maximum capacitance (about 50 pF). Adjust the driven-element length, tip to tip, to about 16 feet, 5 inches. Make sure each half of the driven element is the same length. Connect the swr meter (bridge) in series with the 52-Ohm line at test point A or at any half-wave point along the line away from the array. To the transmitter end of the 52-Ohm line, apply an unmodulated carrier of 28.6 MHz and about a 5-Watt power level. Adjust the swr meter indicator for exactly full-scale indication in the forward selector-switch position. Change the switch to indicate reflected power. Carefully adjust the length of each half of the driven element until zero reflected power is indicated on the swr meter. After the array has been installed on the tower, the variable capacitor is adjusted to correct any detuning of the driven element when it is removed from the vicinity of the ground. The electrical balance of the array is checked as outlined above. ■

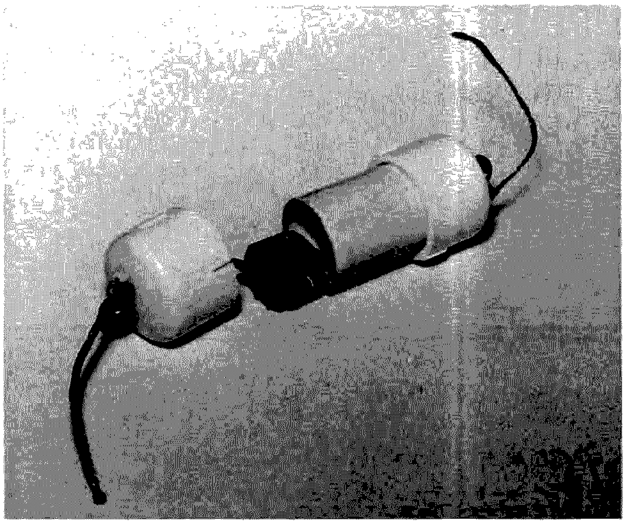
A Little Gem for QRP

The T2FD antenna thinks it's a full-size rhombic. Feeding is believing.

W. Brandon Randolph W8VFT
895 Clifton Road
Xenia OH 45385

While much has been written about antennas in general, little has been published about outstanding radiators for serious QRP work. From reading some of the journals, one would think that QRP is illegitimate unless transmitted from a dipole buried in the basement. Since I do not subscribe to the premise that a second-rate antenna is required to operate QRP, I constructed a QRP version of W3HH's T2FD antenna. This little gem is a real performer, and I would like to share with you the plans for its construction.

For those not familiar with the antenna, a little history is in order. T2FD means terminated folded dipole. This antenna reminds me of a folded-back terminated rhombic. The initial data appeared in *QST* in June, 1949. The next article appeared in *CQ* in November, 1951. *CQ* also published a book called *Antenna Roundup* in 1963. It contained two very informative articles on this antenna.



The terminating-resistor assembly.

I constructed one of these antennas prior to the Xenia, Ohio, tornado in April, 1974. I was using a custom-made high-power terminating resistor, and since it could not be replaced, I did not consider rebuilding this antenna after it was destroyed. By the time we moved to the country, I had forgotten how well this antenna performed.

After moving to the country, we installed a wind-powered electric system, and QRP seemed very appropriate. After optimizing our electric system, I was not willing to operate with a second-rate antenna.

After looking through several antenna books, I ran across my old friend T2FD. The terminating resistor has always been the difficult item to obtain. Since I wanted to operate with five Watts, I figured it should be easy to parallel two-Watt carbon resistors for any value I needed. This was the birth of my QRP T2FD.

The antenna is configured as a sloping folded dipole. One end of the antenna is attached at an appropriate height on a tower or pole and the other end can be tied to a fence post or what have you. In the drawing, you will notice that it is fed with 300-Ohm TV-type ribbon. This antenna can be fed with other impedance lines, but it is beyond the scope of this article to cover all possible designs. If 300-Ohm feedline is not acceptable, I would suggest you research the previously-mentioned articles for complete design information. I chose 300-Ohm feedline because it was cheap and readily available.

Constructing the Terminating Resistor

For 300-Ohm feedline, the terminating resistor is a rather critical 390 Ohms. It just so happens that ten 3900-Ohm, two-Watt resistors in parallel will give us 390 Ohms at a 20-Watt rating. So far, so good. A 1-1/8-inch hole saw will cut two circles in a piece of circuit board faster than I can describe it. These two circles will form the end plates for a resistor cluster pack. Holes are drilled through the board so that three resistors are centered around the middle of the circle. Then the remaining seven resistors are equally distributed around the circumference. This procedure is repeated on the other end plate. When all the resistors are properly aligned with the copper side of the circuit board facing away from the

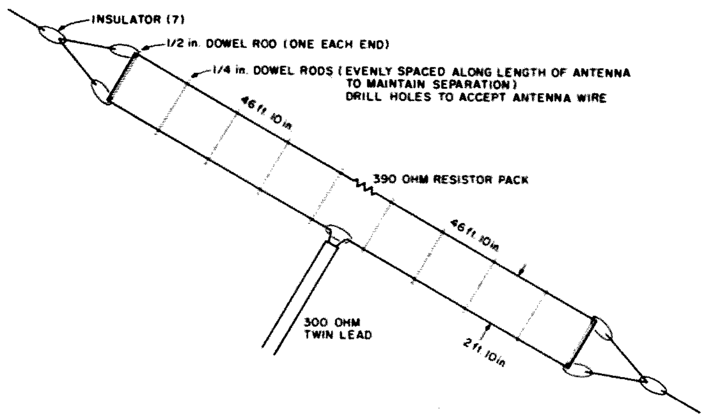


Fig. 1. 80-meter version of the T2FD antenna.

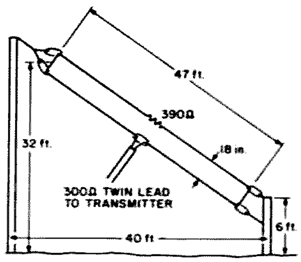

Fig. 2. 40-meter version of the T2FD antenna.

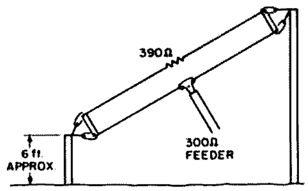

Fig. 3. Erect the antenna so that the angle of tilt is from 20 to 40 degrees for omnidirectional operation.

resistors, the assembly may be soldered. The result will be ten resistors wired in parallel.

This resistor pack will now have to be weatherproofed. The following materials will be needed: one piece of PVC pipe 3½" long and 1¼" in diameter; two 1¼" PVC end caps; two screw eyes with lock washers and nuts; two large flat washers that will just fit inside the end caps; two nine-inch-long pieces of ¼" tinned braid; one tube of GE silicone rubber cement; and a small can of PVC pipe cement.

Drill a hole through the center of the pipe caps. Drill a second hole next to this center hole. This second hole is where the braid will come through. Thread the braid halfway through the second hole. Insert the eyebolt through the center hole. Now put the large flat washer inside the pipe cap, bringing the braid out around the inside. Slip on the lock washer and nut and tighten down the assembly. A little silicone rubber cement will waterproof the hole where the eyebolt and braid come through the end cap. Repeat the procedure for the other end cap and allow both ends to dry.

The next step is to trim the braid on the inside of the end caps to the shortest length that can be readily soldered to the copper foil of the resistor pack. Solder the braid of the other end cap to the other end of the resistor pack. Cement both ends of the PVC pipe liberally and shove the assembly together. Allow it to dry while you work on the remainder of the antenna.

Sticks and Stuff

Since the antenna is for 80 meters, the total length is a little over 90 feet. Separators must be used to keep the antenna aligned. Eight wooden dowel rods 3 feet long and ¼ inch in diameter will fill the bill. For the end separators, we will need two dowels 3 feet in length but ½ inch in diameter. Five small porcelain insulators will be needed, one for the center and two at each end. Plastic separators would be preferable but wooden dowel rods that have been soaked in oil will weather reasonably well.

The two sides of the dipole must be separated by 2 feet 10 inches. This makes it easy using the 3-foot rods. Measure back one inch from each end and drill your holes. These holes should be drilled before the rods are soaked in oil.

Bits and Pieces

The assembly of the wire part of the antenna should be apparent from the drawing. The wire should be cut to the correct length each side of center, and the separators should be threaded on the wire. When this is completed, the center insulator and terminating resistor can be installed. The braid coming through the end caps should be soldered to the antenna wire connected to the eyebolts. This will make a good electrical connection from the resistor pack to the antenna while the eyebolt will take the weight of the antenna off the internal resistors. The 300-Ohm lead-in wire should now be soldered to the center insulator feedpoint.

We are now ready to pull the antenna up into position. It does not matter how the antenna is oriented with reference to the ground. It will probably lie horizontally. This is not important to its operation, but it should slope toward the ground at about a 30-degree angle. This antenna does not require much real estate and should be popular with those living in the city.

Basic design information is included on the drawing in case you may want to scale down this 80-meter version to 40 meters. If constructed as shown, this antenna will operate on all bands from 80 through 10 meters, including the new 30-meter band.

Feeding the Baby

The T2FD is best fed with an antenna tuner. Any balanced-output tuner that will match 300 Ohms to 52 Ohms should do fine. I am using a very uncomplicated home-brew tuner with excellent results. QRP can be very challenging and a lot of fun. This antenna will give good results with a minimum of space needed. Good luck, and I'll be looking for you on QRP CW. ■

T2FD Basic Design Data

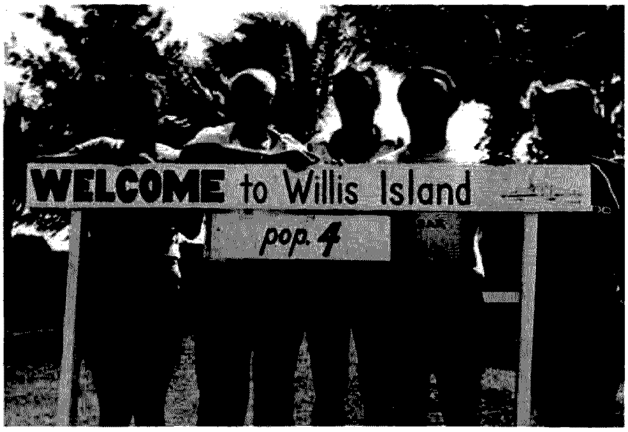
1. The length of each leg from the center is equal to 50,000 divided by the lowest desired operating frequency (in kHz) and then multiplied by 3.28. The answer is in feet.
2. The spacing between radiating wires is equal to 3000 divided by the lowest desired operating frequency (in kHz) and then multiplied by 3.28. The answer is in feet.
3. The sloping angle for a nondirectional pattern should be of the order of 30 degrees.
4. The terminating resistor should be noninductive and have a rating equal to 35% of the transmitter input power.

"The Tops of the Palm Trees"

20,000 QSOs. Coral Sea. Banyandah.

Harry Mead VK2BJL
PO Box 85, Round Corner
2158 N.S.W., Australia

Within the compass of Oceania there are a few DX locations that are rarely visited because of sheer inaccessibility, and they rate highly on the most-wanted lists of amateurs around the world. Mellish Reef is in that category. It is an isolated volcanic peak rising a few meters above sea level from the depths of the Coral Sea, far removed from any shipping lanes and about 600 miles from any habitation—with the sole exception of the small weather crew on Willis Island. Few people have trod the coarse coral sand that hides the volcanic ash and supports vast numbers of gannets and frigate birds who annually nest and raise their young amongst its sparse vegetation. Nor can it be found on any but the most comprehensive maps since it has little significance in any of man's activities.



The team on Willis Island, with Tony VK9ZH, center.

Discovered by the British survey vessel *HMS Herald* in 1827 and charted for the admiralty, the major cay inside the lagoon was named Herald's Beacon. The minor cay about four miles north of it remains uncharted to this day, and it is probable that no human foot has ever been set upon its shores.

The late John Martin VK3JW led an expedition of Australian amateurs there in 1973, and I headed an international group of amateurs in 1978 for a second postwar activation of the reef, but by late 1981, Mellish Reef had once more climbed into the top 50 of the world's most-wanted DX locations. After our 1980 expedition to ZM7, Jack Binder KB7NW had gone down to New Zealand for a refit to his ketch *Banyandah* and was due to return to Australia early in 1982. We had been discussing another DXpedition, and one to Mellish Reef was the logical choice after our hopes for a trip to the Kermadecs had been frustrated.

Jack and I held a weekly sked which now was taken up with detailed planning. First, we established a time slot for the operation: It had to be later than the hurricane season and early enough to take advantage of favorable winds. It was also important that we be there during or near the peak of the equinoctial propagation since the sunspot cycle was rapidly on the decline. The cyclones traditionally move north during April and it would be unlikely that we would have one in the Coral Sea after that date, but on the other hand, the equinox was then five weeks past. The favorable wind would continue for several months, so a compromise was made between the two former criteria and we settled on sailing from the mainland during the first week in May. Allowing for a three-day stopover at Willis Island for some CW operation, Jack calculated that the round trip could be accomplished in three to four weeks.

Our next task was to re-

cruit a crew to man the expedition. There are many factors that influence the success or otherwise of an expedition, but none more than the caliber of the team involved. In this respect, it would be hard to find a better group that had all the vital elements necessary to achieve success. Franz Langner DJ9ZB with Bruce Johnson VK3DHT would concentrate on handling the phone section while Fernando Fernandez EA8AK and I would devote most of our operating to CW.

Once the team was established, the logistics were tackled and sponsorship sought. Jack had purchased two Onan generators, two tents, and many of the vital supplies in Hawaii prior to the Kingman Reef and Palmyra Island expedition. They had been purchased after considerable debate as to the most suitable for use under extreme conditions and had served well on KH5 and ZM7. Rigs and antennas would come from our own resources.

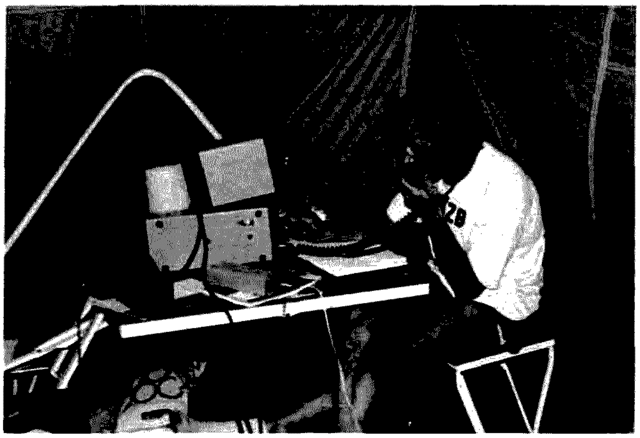
Like all other enterprises, inflation has affected the cost of DXpeditions. Major expeditions are becoming less and less viable; therefore, a substantial donation from the North California DX Foundation was of great assistance to our venture. Nevertheless, the dream of a major annual DXpedition has often gone under from the sheer weight of escalating costs.

We arranged to assemble in Sydney and drive up to Queensland to our point of departure. Fernando had left the Canary Islands early to visit the conventions at Fresno and Dayton and was the first to arrive in Sydney, followed by Bruce a few hours later with Franz arriving the following morning. Jack had taken *Banyandah* up to Bundaberg, and on our final sked before departure asked us to be alongside the dock around noon of the following day so that we could sail on that afternoon tide. He took on fuel, gasoline for the generators, and fresh supplies as we drove north 1500 kms with 25 hours before sailing time (Bruce and I sharing the driving). We gave Franz and Fernando a memorable ride through some of Australia's outback and managed a few hours sleep just north of Brisbane at Caboolture, to arrive almost to the hour alongside *Banyandah* at Bundaberg. With the rigs and antennas stowed aboard, the auto was handed over to be stored in Brisbane awaiting our return. With our personal gear stowed and sleeping quarters allocated, we were ready to sail.

Two hours later we were at the mouth of the river. As the sun began to set and the lights on the shore slowly dropped astern, with sail set and a stiffening breeze we headed out to the edge of the Barrier Reef and the open seas ahead.

The morning of May 3rd saw us clear of the reef on a northeasterly course for Frederick Reef. *Banyandah* was making a steady seven knots in moderate seas, with whitecapped waves rolling along with us, an occasional porpoise rushing across our bows, and flying fish skimming across the troughs of the waves. With only a few puffy white clouds scudding across the sky, star sightings at night and sun shots during the day gave us continual navigation checks and confirmed that we were making excellent time.

Because of the whitecaps, we stood well clear of Samauriz Reef. We looked for the wreck which we had clearly seen on our previous trip, but as we could see the heavy breakers along the reef as we passed along its length, we surmised that she had broken up and disappeared in the intervening years.



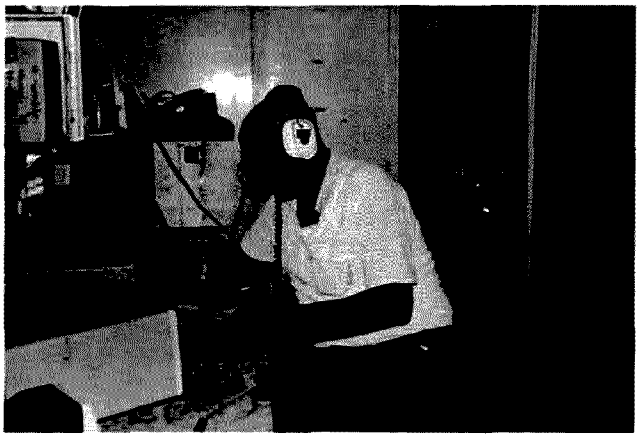
Franz DJ9ZB operating with the TS-520.

On the third night we saw the loom of the unattended light on Frederick Reef and made a running fix as we passed; it would be our last terrestrial fix before we reached Mellish Reef.

The fourth day out the winds slackened, and by nightfall the sails were flapping idly in the soft breeze. Jack started the engines and took the sail in. With less than sixty miles to go, we felt a little disappointed that the wind had not held to see us right in, even though it would have made little difference. The sun would need to be high in the sky to help us to see our way through the reef, and sailing or motoring, we had time in hand.

At daybreak on May 7th, Jack waited for the sun to get high enough in the sky to get a fix and, having done so, climbed the mast, scanning the horizon for a sign of the reef. That we were not far away was evident by the large number of sea birds wheeling around. Another sun shot, a recheck of the calculation, and we were certain that we were on the correct latitude. Were we east or west of our destination? It was an even chance. We could not wait until nightfall to take star sights; a decision must be made. If it was wrong, we stood to lose a day; if it was correct, we would find the reef while the sun was high and we could go in.

The birds appeared to be coming from the west. If that were so, then the reef lay to the west. We turned westward and once more

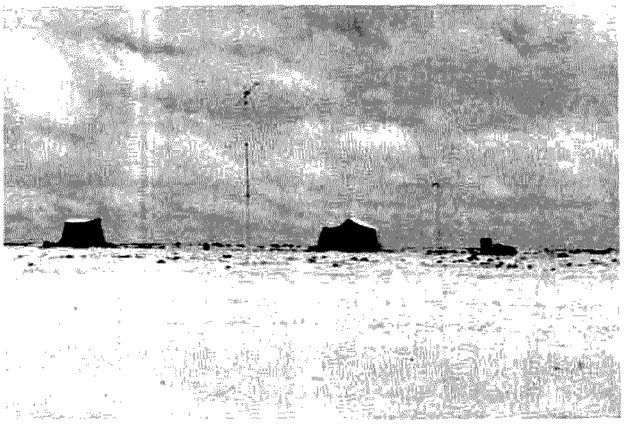


The author operating from the weather station on Willis Island.

Jack climbed the mast and scanned the horizon; in less than an hour he saw breakers to the northwest about five miles away. A new course was set, hands were shaken, backs were slapped, and smiles wreathed our faces as we peered ahead waiting for the breakers to be visible from deck level.

Judith took the wheel; Jack once again climbed to the masthead and guided *Banyandah* closer to the outer reef, carefully threading the ship between the jagged coral heads, black and menacing just below the surface, until we found the charted boat passage inside the reef. The thin edge of white sand was now clearly visible, and slowly we inched *Banyandah* through the gaps in the coral heads, some of which were now just awash, waving their long fronds like cheerleaders at a ballgame. We steadily closed the distance between *Banyandah* and the shore until, 300 yards out, the coral heads surrounded us on three sides. Engines were stopped, the bow anchor dropped, and we halted. A stern anchor went down, the slack was taken up, and we had arrived.

It was still before noon, so we had many hours of daylight left to get ashore and set up. Jack got the dinghy launched and the outboard fitted, and he set off for the shore with Franz whilst Judith and the rest of the crew brought the rigs and equipment on deck. We followed closely our prearranged plan: I joined Franz ashore and we proceeded to assemble one of the beams. Fernando and Bruce followed and, with Jack, erected the first tent. Very soon we were ready to put the first station on the air. The generator started on the first pull; a quick check of the bands showed 15m and 20m wide open, with a few signals evident on 10m. I tuned up the 901DM, called CQ on 14195, and was answered by VK2DJE; within a minute, a pileup had started. I handed over to Fernando, joined the others in getting the second antenna up, and we got Franz away on 21 MHz. VK9ZR was away to a good start.



The operating site on Herald's Beacon.

With everything squared away, Fernando and Franz settled down to a steady rate of QSOs; Bruce, Jack, and I straightened our backs and took stock of the island. Jack and I were dismayed at the devastation of the island now compared to how it had been during our previous visit. The cay had been swept recently by Cyclone Bernie and most of the hardy foliage that had once spread thinly over the surface of the island had vanished. So had most of the coral sand, leaving the fragmented volcanic ash exposed, littered everywhere with dead and rotting carcasses of birds. We counted over 700 carcasses—probably twice as many had been swept into the sea. Those birds which had survived were still distraught and startled, and as the sun set and for long after, they wheeled and screamed over and around the island like a swarm of starlings scattered by a farmer's gunshot. Where previously it would have been difficult to pick a way between the nesting birds, only the occasional hermit crab disturbed the scene. We were later to learn that wind velocities of 180 mph had been recorded in the area as the cyclone passed through.

The standby rig was set up in the sleeping tent, and to enable the expedition to satisfy prior requests to join some of the DX nets, checks were run to see if two stations running on the same band would cause any problems. Using the 18AVT vertical, results were as we had found in the pre-expedition tests: no cross-modulation or breakthrough was experienced on either station that was sufficient to interrupt the QSO rate of any of the stations, and from that time on three stations were running any time conditions allowed.

We had agreed that the cardinal aim of the expedition would be that every amateur who wanted to work VK9ZR would have equal opportunity, and while the beams were turned in the direction of optimum propagation, directional calls would be made only when the sheer size of the pileups made it impossible to do otherwise. An analysis of the 1978 logs had shown which areas had lost out during that expedition, and all operators were alerted to keep a special ear for those areas. The only dead period, when no propagation was possible on any band, occurred between 1600Z and 2000Z, and although a listening watch was maintained throughout those hours, only a CW rag-chew with ZK1VU resulted.

During our stay on Mellish Reef, Fernando had a bereavement in his family, and I would like to record our thanks to the operators, worldwide, who kept the channel clear while he was passing and receiving traffic back home. When the chips are down, the vast majority of amateurs prove that they are the gentlemen we assume them to be.

By the second day, we had passed the 8000 QSO mark, equipment and generators performed perfectly, the sun shone, and a swim in the lagoon was a welcome refresher. My recollection of previous expeditions gave the impression that the pileups were bigger this time than I had previously experienced, but I could be wrong. Bruce, who was taking part in his first DXpedition, handled his share like a seasoned DXer. 80- and 40-meter propagation was not as good as we had hoped; the number of QSOs on those bands was disappointingly low. Even so, every station we heard made a contact.

On the third day, we received the news that weather conditions were deteriorating; a number of dark clouds appeared in the sky, and in the evening freshening winds blew down one of the beams. No damage was done and it was quickly reerected. In the process, we discovered metal stakes buried in the sand that were from our 1978 expedition, and one of them served a second term of duty.

We passed our target of 15,000 QSOs on the fourth day and decided, in view of the rising winds and the knowledge that a cyclone was developing to the west of us, that we would close down on the following day. At daybreak we started to dismantle the sleeping tent

and gradually move the equipment back to *Banyandah*. As the day progressed, we continued to pack up until only the vertical antenna, one generator, and one rig remained. The pileup was still wide and deep as we waited for the last run from *Banyandah* to take us off. A final QSO with WA6ZWE at 0423Z, and the Mellish Reef 1982 expedition was over. Back aboard, the gear was again stowed away securely, anchors were weighed, and *Banyandah* once more picked her way through coral heads towards the open sea. Almost one hour after our final QSO, Herald's Beacon slipped below the horizon and we were setting course for Willis Island.

The team: L to R, Fernando EA8AK, Franz DJ9ZB, Harry VK2BJL, Bruce VK3DHT, and Jack KB7NW.

The second leg of our Coral Sea DXpedition was to provide the excitement of the voyage, for whilst the trip to and the operation on Mellish Reef had gone according to plan and our best expectations were realized, the homeward leg via Willis Island was menaced by Cyclone Domenic and the aftermath right up until we reached the lee of the Australian coast close to Cairns.

The course to Willis Island from Mellish Reef took us close to Magdalene Reef from whence we set a course to approach Willis Island from the southeast. To reach Willis in the forenoon, Magdalene Reef had to be passed during the hours of darkness and spot-on navigation was essential. Many anxious hours had been spent on the previous expedition peering through the darkness for breakers on a moonless night whilst listening for a 2m signal from Bill VK9ZM on which we could take a bearing. This time we had no 2m signal, but there was a waning moon.

The winds had risen to almost 40 knots after we left Mellish, *Banyandah* was lively in the rising swell, and wet tails were the order of the day as the lee rail dipped under and green seas swept into the cockpit. We were running under a reefed mainsail and peaking to 9 knots; Cyclone Domenic was only 400 miles to the east of us and we were getting the edge of its fury. At that stage it was stationary and we anxiously waited to see which way it would move.

We did not sight Magdalene Reef; Jack calculated that we had passed it 12 miles to our south when we altered course for Willis Island, and he took in more sail to make sure we did not run down on the reef in the early hours of the morning. The weather crew had promised to put on a navigation light at the top of their radio mast, but we did not see it, and Jack hove to until daylight before continuing on our course.

It was around seven in the morning when we saw the tops of the palm trees on Willis Island. As we came closer, we saw heavy seas pounding on the reef and rolling into the lagoon, and as we moved round the island to find a lee shore in which to make our approach, we could see the weather crew against the white building watching our progress as we cautiously approached the anchorage.

Jack put down two anchors for safety, unshipped the dinghy, and one by one we were transported ashore. Tony VK9ZH welcomed us on landing and introduced us to the rest of the weather-station crew: Arthur the skipper, Athol, and Jerry. We had brought mail and some urgently needed supplies, not the least of which was a replenishment of the beer and cigarette supplies for Jerry, who, in a moment of bravado, had quit smoking and consigned the remainder of his six-months supply to the ocean only to change his mind the following morning. He had spent nearly two months regretting his action whilst he waited for our arrival.

After a hearty breakfast, we each indulged in the luxury of a hot shower (the first since leaving the mainland) before we were offered a space in the operations room to set up our station. The vertical was set up on the lawn outside the main building and the beam used by Tony was put at our disposal. I opened up on 20m CW at 2316Z, several hours earlier than our anticipated arrival. Our original plan had been to stay for 48 hours, but the winds from Domenic remained steady at 40 knots and the seas were even heavier than when we arrived. The tops of the palm trees, bent over in the wind, conveyed the force of the gale.

Conditions on the air had deteriorated, too. Propagation to the east coast of the USA was poor on all bands, and to most of the USA it was only moderately good. There were a couple of short openings to Japan on six meters and a few European contacts on 80m. We explored the island while away from the rig, observing the birds nesting in the same manner we had expected to find on Mellish Reef. Willis Island is also a breeding ground of the large turtles, and the eggs that they had laid on the island were now hatching so that baby turtles were seen scuttling down to the ocean, so small that they nestled cozily in the palm of a hand.

Good rains over the past six months had made the grasses and wild flowers lush and verdant and the buttons of the yellow and violet wild flowers formed garlands around the nests of the sea birds, with their eggs or chicks. They showed no fear of us as we quietly observed them in their habitat. The rains also had replenished the weather station's water supply and the storage tanks were full.

We were impressed by the routine of the weather-station crew in their collection of weather data and dedication to the maintenance of station buildings and environs; the remoteness of their isolation was brought home even more when we saw by the visitors list that fewer than 70 people had called in the past 60 years since the station was established!

As the time of our scheduled departure approached, we watched the weather pattern over the area, hoping for a change. Domenic appeared to be weakening and moving slowly away from us, but the winds still remained a steady 40 knots and the sea was still heavy enough to make the run out to *Banyandah* a hazard.

Added to this, the run from Willis to the mainland was an obstacle course with more reefs and the narrow Grafton Passage through the Outer Barrier Reef. Flights out of Australia had already been booked, however, and Franz and Fernando would incur a heavy financial penalty if they were missed, adding to the burden of an already costly expedition. Naturally, they were anxious to leave according to schedule.

Jack, aware of our predicament, left the decision to us but nonetheless counselled caution and advised us to delay our departure by 24 hours. Arthur, with his access to so much data, consulted the meteorological center in Townsville and added his weight to Jack's advice. A delay of 24 hours would still allow flight connections to be made, but there was no guarantee that the weather would improve; it was at best a 50/50 chance. We bowed to their superior wisdom and settled down to another day of operating.

Banyandah had shifted anchorage several times during our stay when anchors dragged or the shelter of the land proved inadequate to the safety of the vessel. Once she lost an anchor which had to be dived for the next day.

When the sun rose on the morning of the 17th of May, the wind was still maintaining its velocity and we decided that we could delay no longer. All the gear was carefully sealed in plastic bags and taken down to the beach. The dinghy raced through the surf and was almost on end as it crashed through the crest of the breakers. Jack had insisted that we wear life jackets, so we were relieved when all of the crew and gear were safely aboard *Banyandah* without damage or a dunking. It took most of the day before everything was stowed away and then, when we were ready to leave, Jack discovered a fouled anchor which required a further hour to clear from the coral shelf under which it had wedged. The sun was setting when we got under way, and with a farewell wave to the group watching us from the shore, we turned our bow away from the island and into the wild seas beyond.

To clear the dangerous areas in daylight, Jack calculated the speed we should make to come up to Swain Reefs during mid-morning, but the winds pushed us along well in excess of that requirement and the light sail was shortened still further to slow us down. Sleep was difficult, but the securest way to be in those high seas was horizontally polarized in our bunks. Calmer seas brought us on deck soon after daybreak, however, and we were in the lee of Swain Reefs. Inside the line of breakers to our north and extending to the horizon, the coral heads loomed dark beneath the surface, picked out by the sandy bottom reflecting through emerald water. On our last trip, there had been a Taiwanese fishing boat high on the submerged coral, her bottom ripped out by the jagged spurs, but like the wreck on Samauriz, there was no trace of her either.

In the calm lee of the reef we dropped anchor and had a hearty breakfast. We had gained several hours on the run from Willis Island and the wind had still not abated. Weather reports were coming in that a change was on the way—that Cyclone Domenic had moved still further east and was dying out. By delaying our departure from Swain Reefs for several hours, *Banyandah* would see the lighthouse on Euston Reef (marking the southern side of the Grafton Passage through the Barrier Reef) in the early morning of the 19th.

Leaving Swain Reefs, we were now moving into the lanes of north- and southbound shipping along the Australian coast, standing well clear of the mighty Great Barrier Reef. Several ships were sighted as we continued our homeward leg and, as Jack had predicted, we sailed past the Grafton light early in the morning. We were awed by the fearsome seas that pounded over the reef, which stretched away to the south as far as the eye could see. We were six hours away from Cairns now; soon Green Island was clearly visible on our starboard bow, and then came the outline of the coastal mountains and the channel leading to Cairns harbor. The harbor master allocated us a berth alongside the main cargo quay; lines went ashore, and with *Banyandah* secured, we relaxed into an emotional scene of mutual congratulations.

Several hours later we saw Franz and Fernando off to the airport; Ray VK2BKD was to meet them in Sydney and entertain them until their homeward flights. Bruce and I stayed on another day unloading the equipment and arranging its shipment down to Sydney, and the following day we flew down to Brisbane, collected our car, and began the long drive back to Sydney. A sack full of QSL cards had preceded us, and now began the long task of checking logs and preparing a QSL card suitable to the occasion.

Between Mellish Reef and Willis Island we had made over 20,000 QSOs to 132 countries on all continents, we had enjoyed the comradeship of a team of operators under difficult and hazardous conditions, and we resolved to undertake another expedition together sometime in the future. ■

How to Gain with PVC

This could be history's cheapest quad. Try water pipe on 2m.

To find out why I need a very portable, high-gain 2-meter antenna, first you must understand a bit of both ancient and recent California history.

About 15 million years ago (an extremely short while, geologically speaking), the Earth groaned and shuddered; huge rock plates cracked together, and the spiny hills known as the Sierra Nevada started to rise 20 to 30 thousand feet into the air. Huge volcanoes resulted from this immense pressure and uplifting, and these 30,000-foot peaks belched smoke and lava, breaking themselves into smaller hills (like Mt. Whitney, "only" 14,000 feet high) and deep valleys, which in time became huge lakes. Lake Tahoe, 6000 feet high and unknown thousands of feet deep, is the result of one of these huge cindercones blowing its top and then collapsing back in upon itself, a classic case of a mountain lake surrounded by peaks many thousands of feet high.

At about this time, Tehama, one of the minor volcanoes of the range, also ex-

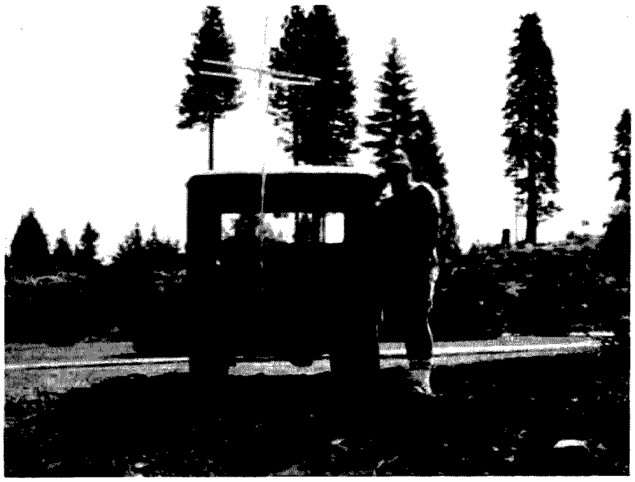

Photo A. The author, with quad mounted on the jeep.

Photo C. The balun attached to the quad driven element.

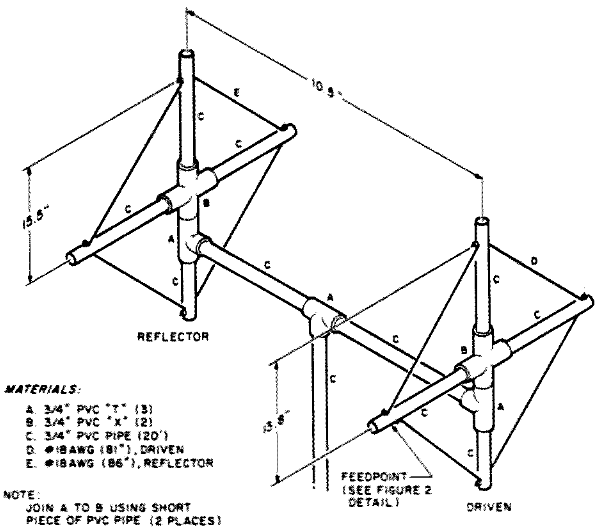

Fig. 1(a). PVC quad.

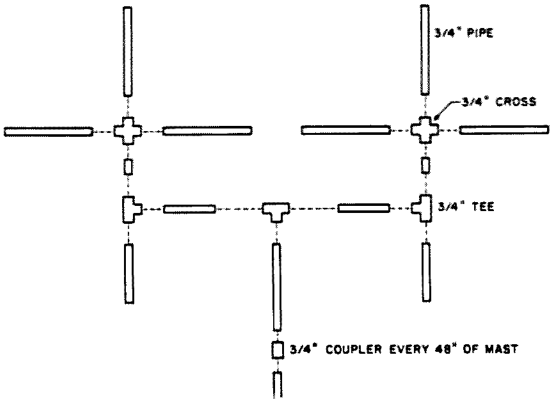

Fig. 1(b). PVC assembly.

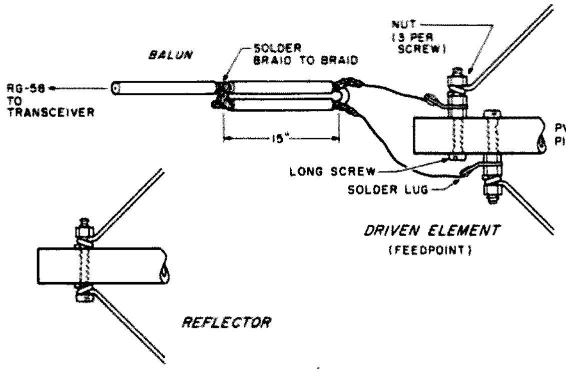

Fig. 2. Feedpoint and balun detail.

ploded, creating a secondary volcano called Mt. Lassen. In the process, a deep lake surrounded by peaks, called Lake Almanor, was formed. Later, about a million or so years ago, an earthquake created a crack in the hills surrounding Almanor. The escaping water created the Feather River and its deep canyon.

Now for more recent history. A couple of years ago, a local group of pilots decided to hold a rather unique air race. Instead of merely the fastest being the best, this group decided to award a trophy to the airplane that hauled the biggest load on the least fuel the fastest. They called this 400-mile race the "Competition for Aircraft Fuel Efficiency," since shortened to the CAFE 400.

All of which brings us to the present day. One of the checkpoints in the race is an island in Lake Almanor, and the race folks wanted reports from Almanor back to race headquarters in the Sonoma Valley, some one hundred fifty miles away, preferably on 2 meters. In case you don't get the picture yet, let me paint it in vivid colors: Here I sit on an island in the middle of a lake, surrounded by hills 3 to 4 thousand feet high in every direction, with no ac power, no telephone, and a mission to communicate via 2 meters to another station 150 miles away, which is further tucked into another valley blocked by another mountain range 4500 feet high!

Fortunately, this deck has 3 aces and I drew them all. First, there is a little knoll on this island that will get me up 500 feet above the lake. Second, the Feather River Canyon, although only half a mile wide, is 3000 feet deep, 40 miles long, and pointed directly at Sonoma. Third, Sonoma has a 2-meter repeater on one of those 4500-foot peaks just outside of town.

And the ace up my sleeve (without which we would have lost the game) is my portable quad antenna. 50 Watts and a vertical dipole bought us absolutely nothing, but with the quad antenna described below, signals were Q5 both to and from the lake. See Photo A.

There were some specifications on this quad, though, that made it rather unique. First of all, the entire antenna and mast needed to be disassembled and packed into a bundle of sticks no longer than a meter and a quarter (48"), a size suitable for backpacking (if necessary) a considerable distance. Second, it needed to be put together in 15 minutes or less. Third, of course, it needed to be cheap, cheap, cheap. See Photo E.

I decided to make the entire antenna-supporting structure from 2-cm (3/4") polyvinylchloride (PVC) water pipe and fittings. Photo B shows the general construction details, and Figs. 1 and 2 show construction details of the quad. In working with PVC fittings, I found that the fittings were all tapered, with the result that if the pipe was inserted firmly into the fitting, the assembly was rigid enough to stay together without the use of pins, glue, or keepers of any sort. Furthermore, the joint so made is rotatable with a bit of elbow grease. This allows the quad to go from horizontal to vertical polarization (and anywhere in between to allow for polarization-rotation bounce off the canyon walls) in a few seconds time.

For those of you who have never done any aviation antenna work, the balun shown in Photo C and Fig. 2 may appear strange. Note that the center conductor of the coax does not attach to *anything* at the antenna end, and that the antenna is connected to only the shield braid of the coax. The loss, though, is about 0.1 dB, the balance is near perfect, and the transformation ratio is 1:1. (Note also that this scheme grounds both elements when this balun is used on a dipole—affording cheap and automatic lightning protection.) The balun fastens to the quad element by means of solder lugs. Photo D also shows that the balun is firmly laced to the PVC frame; if the balun is not supported, the coax braid will break at the solder lugs.

The quad elements themselves are AWG 18 wire.

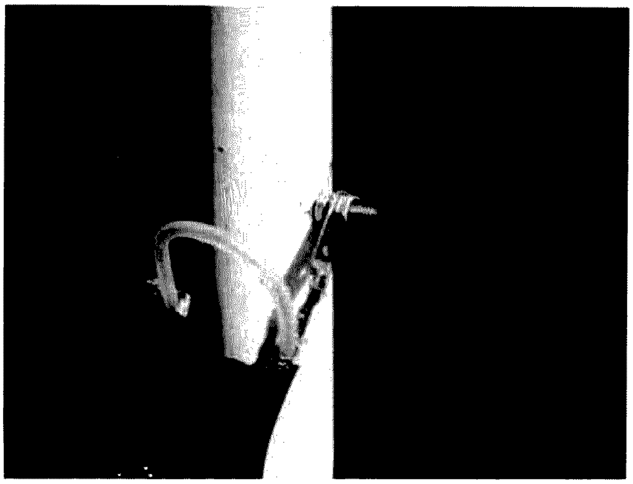

Photo D. A closeup of the balun attach point.

Photo E. The quad disassembled into a box of fittings and a pack of sticks.

There is nothing sacred about this size; my company uses rolls and rolls of the stuff, so I got it off the shelf. AWG 18 gave us a 1.5:1 vswr bandwidth of about 3 MHz. If you need more bandwidth, use heavier wire.

The proof of any antenna is its gain. While I have not been able to sniggle any free time on the company antenna range for this product, a bit of field testing using a calibrated Kenwood TR-7400 shows the gain of this quad to be between 6 and 8 dB above a reference dipole. The most repeatable measurement indicates a gain of 6.5 dBd. There are many narrow, deep nulls on the backside of the quad, so that a true front-back ratio is hard to define. I *can* comment that a machine in Reno that was giving me fits at Almanor completely disappeared into a null that was measured later in excess of 30 dB. The main beam is fairly wide; eyeball measurements show the 3-dB forward beamwidth to be about 30 degrees wide.

Many thanks to Ron N6AUB and Grover KC7IW for their help in field testing. Also many thanks to the ghost of Mt. Tehama, whose explosion created the need for this antenna. ■

Helicoids

Few people understand how to build these versatile whips. This article takes care of all the ifs, ends, and butts.

When first employed as a tech rep, I found myself on the move quite often and had a definite need for a portable antenna. I figured that I could kill two birds with one stone and rig up something that I could use in both my job and my hobby, amateur radio.

Sometime in the past, I experimented with a ground-plane antenna utilizing expandable and retractable whips which when simply adjusted to the correct lengths permitted operation on the frequency of choice. Some of you ex-bush monkeys from Southeast Asia ought to remember the 292 ground-plane antenna—a beast to lug around the boonies. Well, at the time, I was trying to come up with a smaller package.

In any case, with that old idea in mind, I decided to try out the same principle in conjunction with helicoidal-type antennas. The main problem was in obtaining a quick disconnect to join the heli form to the whips.

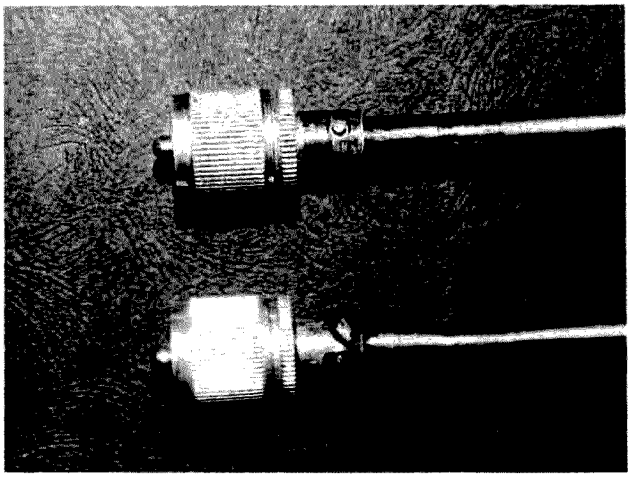
After much fooling around and wasted effort, I decided to use the UHF-type connectors with a barrel in the heli forms and a PL-259/U-type connector on the whip. This called for a much larger heli form which resulted in the antenna being able to handle 500 Watts or more for power with the connectors providing a good solid rf connection.

All in all, it resulted in an antenna that was capable of being used on 21 MHz through 30 MHz with a 500-Watt capability. With the heli form being the largest element in the package (25½ inches), the antenna was what I called suitcase compatible.

Basic Fundamentals

The use of expandable and retractable whips as capacitance hats helps prove the saying that every little bit helps. The elements also radiate and by virtue of their length provide more capture area for the received signal.

According to the formula for resonance, the frequency is inversely proportional to the square root of either L or C; changing either one would result in a frequency shift. If an inductance value could be found that was compatible with the capaci-



Harada whips joined with the UG-273/U connectors.

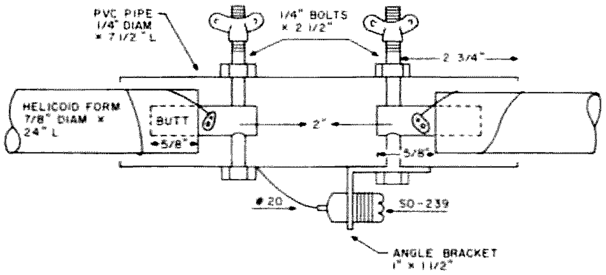


Fig. 1. Both helicoids mounted within the PVC pipe mount. The two wing nuts are used for mounting to the phenolic mast mount.

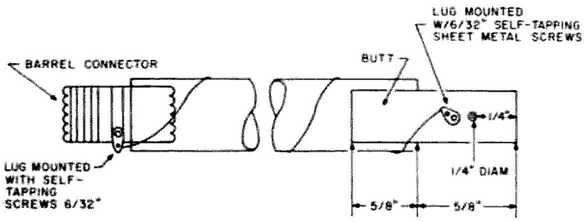

Fig. 2. The tip and end of the helicoid with the barrel and butt epoxied in place.

tance value of the whips, then tuning over a specified range of frequencies would be possible.

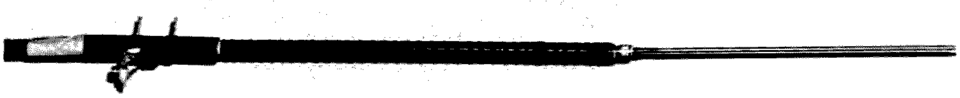
Armed with that basic research, a suitable induction value was determined by empirical design and found to be compatible with the formulas for induction and the number of turns for a closely-wound coil.

With this, I now had a base frequency to start with. Simply expanding or retracting the whip elements should permit me to tune up to the next highest frequency; a grid-dip meter told me my base frequency was 21 MHz and (much to my surprise and delight) informed me that I could tune on up through 30 MHz.

In any case, before you start construction, let's be realistic: This antenna is not going to compete with any beam or dipole 100 feet up in the air, although I have given some reasonable competition (by logging in 48 countries with these antennas). There is one thing that is certain: You will be able to get a good signal out in what I term a hostile environment.

You will need two sets of whips; I purchased mine from Harada Industries of America for \$3.95 each. They are perfect for this application in that they are solidly constructed, are of stainless material, and expand out to approximately 50½ inches. The model number is ST-13 (3TS-1300F) and they are available at most auto supply houses.

I needed two additional sets of whips for the 28-MHz-through-30-MHz band, as I didn't want to cut the Haradas—their full length was needed when using the antenna in the vertical configuration. So I used two sets of the conventional type used for FM radio (consisting of three sections, each section 7¾ inches long); these are good as they make good electrical connections when expanded and shortened and give you the frequencies needed if you are concerned with any commercial activities. In any case, I picked up a couple of them in a shopping mall for two bucks.



Antenna used as a vertical with the ground side of the helicoid replaced with a radial.

Assembly

Take the two barrel connectors prepared as in Fig. 2 and mount a terminal lug over the 6/32-inch hole; tighten down with a metal screw. Do the same thing with the brass butts.

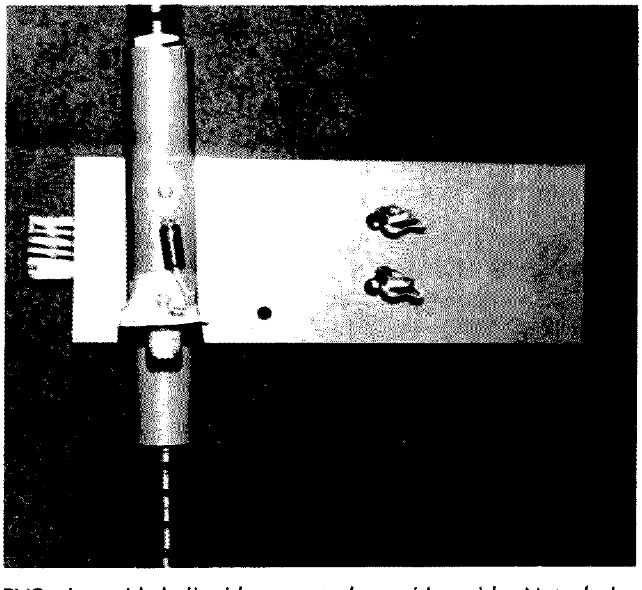
Obtain the two helicoid forms (7/8-inch diameter × 24 inches long); insert the barrel connectors into the form right up to the lug. Using 5-minute epoxy, seal the connectors to the form; repeat with the butts, making sure that their ¼-inch hole is left on the outside.

If the butts and connectors do not conform to the inner diameter of your form, you may have to file the connectors down or wedge them in place. Make sure that you have good solid straight connections.

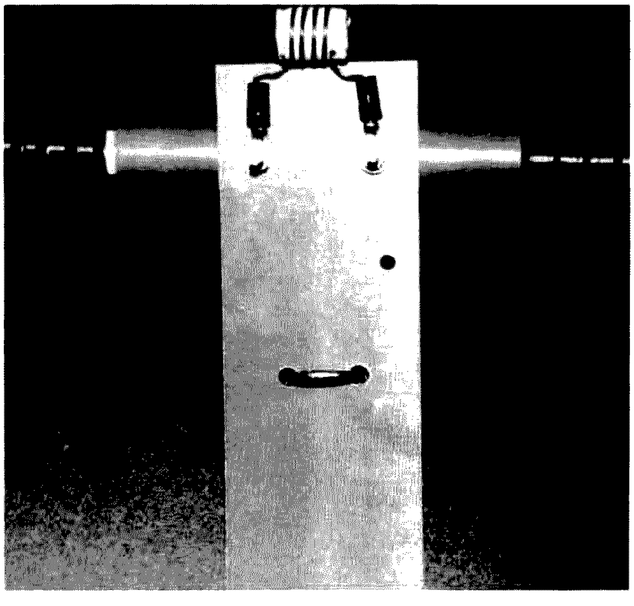
Measure down from the lip of the form on the barrel connector side 4-3/8 inches and scribe a mark; this will be the beginning of the loading coil winding which is simply an extension of the helicoid wire.

Take 133 inches of #20 enameled wire and solder one end to one of the butts. Begin your winding right on the edge of the form, maintaining a ½-inch pitch winding for 16 turns and then a ¾-inch winding pitch until you reach the loading coil mark.

At this point, I suggest taping the winding to keep it in place. Start winding 7 turns close-wound as tightly as possible; on the last turn, I would again use tape to maintain the coils' integrity. Continue the windings up the rest of the form with ½-inch spacing and solder in place.



PVC pipe with helicoids mounted on either side. Note hole used for tilted dipole.



Matching coil mounted on the butt bolts.

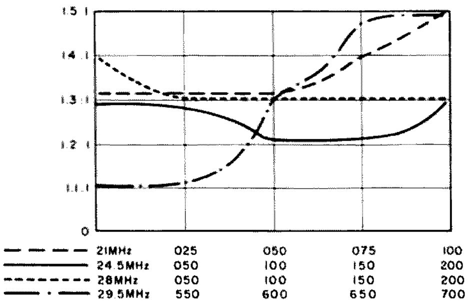


Fig. 3. Swr curve for antenna used in the dipole configuration and set up 15 feet above ground. Refer to the text for whip lengths.

You will have to do exactly the same thing with the second heli form, taking care that the winding follows the same axis as the winding of the first form (see Fig. 1).

At this time, I had to prepare the UG-273/U connectors, 4 for each of the whips. I had to break away and remove the plastic that was around the center pin to ensure that when I filled the BNC side with solder, the center pin would be shorted to the main or ground side of the connector's housing.

You should at this time make sure that the inside of the BNC side of the UHF connector is completely clean, as well as the end of the whip which will be inserted into it. Fill the BNC side with hot solder and insert the whip end into it, making sure that you have a good straight connection. When it is cooled, check with an ohmmeter and make sure that the whip, the main housing of the connector, and the center pin are one connection, as this will mate with the barrel connector on the helicoid form.

When I was trying to match up the 50-Ohm coax with the heli dipole, I experienced some problems. At first, I simply hooked the coax directly to the dipole; this would have worked, but I was not entirely satisfied with the swr. I then went to a 7-turn coil shunted directly across the two bolts that held the helicoids to the mast plate. This brought me into an acceptable range, but when I put the swr meter directly into the antenna, my swr was something other than what it should have been. Back to the drawing board.

I finally ended up with a coil with the exact same dimensions as the helicoid; in fact, I used a leftover piece from it. The form is 1 inch long. Approximately 1/8 inch in from each end, I drilled a 3/32-inch-diameter hole. I then wound 4 turns of #20 enameled wire (same that is used on the heli form) and left 2-inch pigtails. (Before I forget, the windings are spaced 1/8 inch apart; the two pigtails are then terminated with ¼-inch spade lugs and the whole affair is smeared with 5-minute epoxy to keep the coils in place and give protection from the elements.) This brought the swr at the antenna input practically down to a flat response with good power output; also, the coil seems to alleviate somewhat the problems of nearby objects having an effect on resonance.

I used a phenolic plate for my mast mount. I took a piece 3½ inches wide by 8 inches long by ¼ inch in thickness. Two inches in from one end, I drilled two holes to match the two bolts that come out of the PVC pipe mount. When the plate is mounted over the bolts, it makes an ideal place in which to mount the coil. About 3 inches down from that, I drilled two more holes for the single U-bolt that would hold the whole affair to some kind of mast.

Last but not least was the PVC pipe mount to hold the helicoid forms. I experienced some problems with this because with the wire on the heli forms there was not sufficient room to insert them into the pipe. I simply took a rasp file and filed down the inner diameter on each side of the pipe to provide a secure fit for the heli forms. When you drill the two 2-inch-spaced holes in the pipe, make sure that they are exactly parallel so as to properly align the butts of the heli.

Take one heli form and insert it into the PVC pipe, aligning the butt hole with the hole in the pipe. Take the SO-239 mounted on the bracket and insert the ¼-inch bolt through it into the PVC pipe, on through the butt, and out the other side of the pipe. Tighten it down with a nut and mount the other heli form on the other side in the same manner. Solder a 2-inch piece of #20 wire to the center pin of the SO-239 and terminate the wire with a ¼-inch spade lug. Take the lug and insert it beneath the second heli bolt and tighten it down. This completes the construction of the antenna.

I would recommend tapping the holes for the butts. I didn't have any taps available at the time and I force-fitted the bolts through the brass butts, making my own threads with little difficulty.

At this point, you should have the phenolic plate mounted and the coil secured with the two wing nuts; connect the two Harada whips to the ends of the helicoid.

Testing

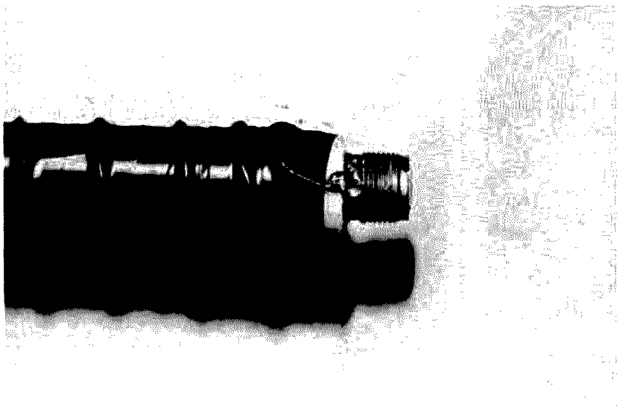
We will not refer to the first section of the whip for adjustments—only the 2nd and the tip "end."

Connect the RG-8/U mini coax; I used 32 feet because that was all I had left and I found it sufficient for my needs.

Adjust the 2nd section for 9½ inches, the tip extended. You can start your checking at a height of 5 feet or 15 feet, whichever is practical for you.

Apply just enough power from the transmitter to establish an swr ratio. It should be rather small. Apply power and the swr should approximate the one in Fig. 3. I used 100 Watts into the antenna. If the swr isn't satisfactory, check the dial of the transmitter and test at a high and low end to determine the whip length.

For instance, if your swr is minimum at 300 kHz and you want, say 50 kHz, extend the whip length about one inch at a time and recheck. I used high-voltage fuse pullers 16 inches long. With a companion for safety and much reduced power, I simply adjusted right in for



Barrel connector mounted on the end of the helicoid.

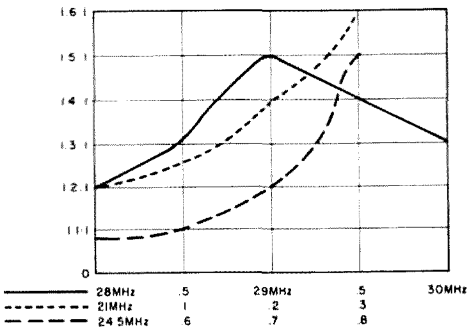


Fig. 4. Swr curve for one section used as a vertical. Readings were taken at a height of 10 feet. Refer to the text for whip and radial lengths.

minimum swr. I wouldn't use this method unless highly-trained personnel who know how to react in the event of an emergency are present.

For the 24.5-MHz band, adjust the whip's 2nd section to 3 inches and the tip to 7½ inches; apply the same technique.

For 28 MHz on up, use the FM whips. On 28 MHz, the whip is adjusted for a total length of 19½ inches, using each section.

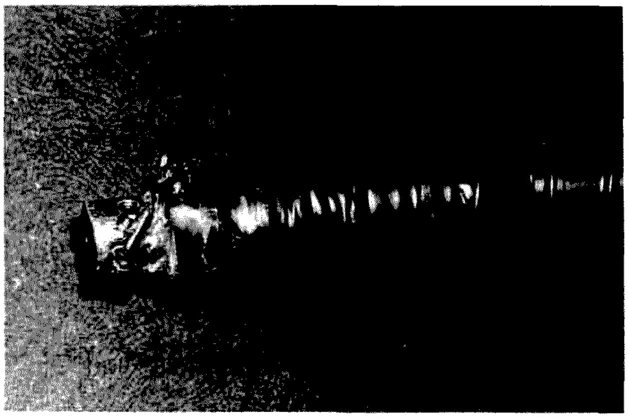
For 29.5 MHz, adjust the whip for a length of 15 inches.

Testing for the Vertical Mode

If you say that you don't have enough room to get a heli dipole up in the air, how about a short vertical with one radial ("Great shades of Marconi!"), perhaps mounted on a camera tripod about 3 or 4 feet high, in the living room, out in the yard, or perhaps up in the air about 40 feet?

Well, just remove one heli form from the ground side and make sure to replace the bracket with connector, bolt, and wing nut which will be used to secure the radial.

Hook up the RG-59/U coax (I used 50 feet) and don't forget one Harada whip extended all the way. Connect one radial (10 feet long, about #14 vinyl-jacketed wire) to the wing nut and apply power at 21 MHz. Your swr should approximate the one in Fig. 4. Just let the radial do its thing, lying along the ground or hanging beside the mast. If you find that adjustment is necessary, adjust the radial about ¼ inch at a clip, but tried and proven events dictate that this shouldn't be necessary.



Brass butt mounted in the helicoid form. Note the threaded hole for rf connector with a ¼-inch bolt.

On the 24.5-MHz band, adjust the Harada 2nd section to 6 inches, the tip to 7½ inches, and the radial to 9 feet, 6-3/8 inches.

For 28 MHz through 29.5 MHz, adjust the tip only to 6 inches and the radial for 7 feet, ½ inch.

You may want to do as I have done and make up some stubs with phone jacks so that removing one stub will permit resonance on the next highest frequency. This alleviates the problem of carrying around a complete set of radials.

A good swr meter and a noise bridge are really essential for testing. This completes the test for the vertical mode.

Conclusion

You shouldn't experience any difficulty in, obtaining resonance with this antenna. I primarily set up all parameters in the low ends of the bands so that there is ample adjustment left to permit operation in your favorite portion of the band.

The swr is sufficiently low so that if I feel like working some SSB, I leave my little Kenwood AT 130 antenna tuner in the line and just touch up a little bit, leaving a complete flat response.

It is a fun antenna to work with, especially when there are 10-meter band openings. I also found it useful for instructional purposes. Being compact, it lends itself to a classroom nicely; a student can have hands-on application in adjusting for resonance, observing swr power relationships, and even trimming the radials.

Most of the parts used in the construction may be substituted for, such as the material for the heli form, the PVC pipe mount, and the coax connectors. You even may want to operate in just one favorite portion of your ideal band. If so, you may replace the whips with something more permanent, such as a piece of brass welding rod or a section of mobile whip antenna. You then will just have to find the correct resonant length for that band.

I have heard a lot of pros and cons with regard to short antennas, ground losses, crunching effect, etc. But I for one have had a lot of fun pursuing my hobby where otherwise I may not have been able to do so.

I would like to make one last comment on the design: The loading coil that I selected is at best a compromise. I could have selected a coil for each band and made the swr as tight as a drum, but this would have entailed changing coils for each band; accomplishing this in the evening, perhaps in the dark, would present problems (dropping a nut, coil, etc.). Changing a whip presented no problem as to selecting the proper length, especially if the elements are grooved so one can touch-sense the correct length for the desired band. In any event, at this time the swr is sufficient for typical operation.

Anyway, some of you antenna buffs should be getting some ideas about a compact beam, maybe a reflector 5% longer with extra optimized spacing. Who knows, it may work.

For you apartment dwellers, you may want to hang the vertical out over the balustrade and put a flag on the end of it.

The most classical approach I have ever seen was undertaken by a friend of mine. He took one of my verticals and had it mounted inside a 2-inch-diameter-by-30-foot piece of PVC pipe; he then mounted a coax connector at the base and just let the radial hang within the pipe. To top things off (as the old saying goes), he then constructed a model TV antenna, spray-painted it with silver paint, and mounted it on top of the pipe to justify the pipe's presence. With that, I'll have to say good luck and 73. ■

The Big-Car Break-Down Beam

Try two-meter luxury the easy way.

Involvement with the local RACES/ARES organization (the Radio Amateur Civil Emergency Service/Amateur Radio Emergency Service) prompted a search for a quick-setup beam antenna to enhance two-meter communications when operating from a vehicle at a fixed location. This article describes the beam, mast, and guying that I came up with. The assembly is called "The Four-Minute Beam" because it can be set up by one person in less than four minutes. For two people working together, it's a piece of cake.

The beam selected was a Cushcraft A147-4, a four-element yagi with a boom length of 44" and a weight of only two pounds. The design of this model is ideally suited for the application. It was necessary only to replace the hex nuts with wing nuts to make it a knock-down, quick-assembly beam and add a stack of spacing washers to allow the mounting U-bolt to be pulled up snugly around the small diameter mast. The disassembled beam is stowed in the original shipping carton modified to become a storage box.

The twelve-foot mast is made up of four pieces of telescoping .058"-wall aluminum tubing. The largest is 1-1/8" in diameter, and the longest piece is cut to a length of 56½". The four pieces telescoped are then stowed in the storage box.

Construction of the mast consisted merely of cutting the pieces to length and making a longitudinal hacksaw cut in the ends of three of them. See Table 1.

A small hole (about 1/16") is drilled 14" from the bottom end of the 3/4" piece to provide an indication of the proper extension of the top section when the mast is erected. A stripe of paint or nail polish is easier to recognize, but the hole remains as a reference if the stripe is scraped off as the sections are telescoped.

The stainless-steel hose clamps around the slots in the three outside pieces are used to clamp the sections of the mast together when extended and also to keep them from sliding apart

Photos by Jim King WB3JZI

Photo C. Beam and transmission line installed; mast being extended.

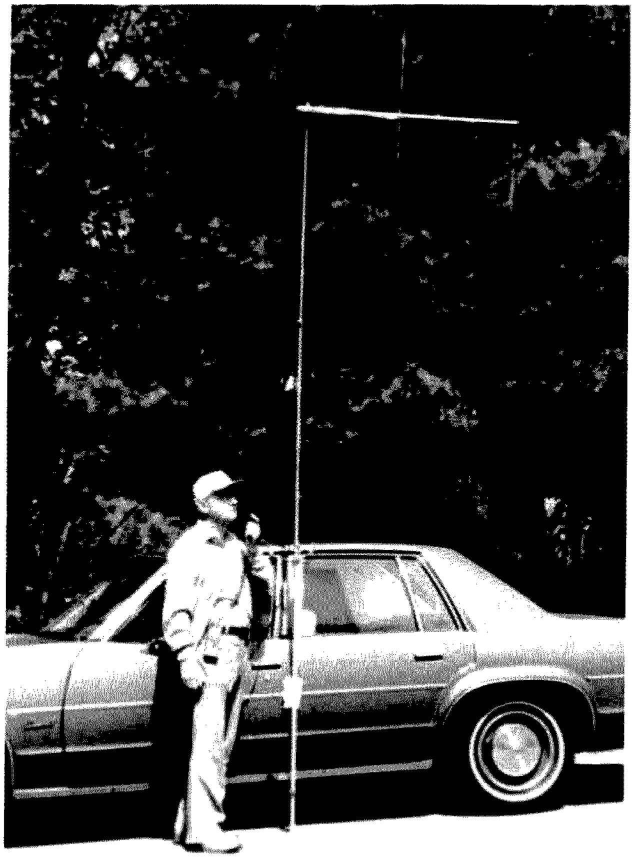

Photo D. Mast fully extended. Beam being used with HT.

while being handled. The 1-1/8" piece acts as a stiffener for the bottom section and also allows the beam to be rotated and clamped in the desired direction.

In operation, the mast is secured to the side of the automobile with stretch cords (bungees) with the bottom section resting on the ground. One cord is hooked under the frame, and a second one is hooked to the roof gutter. Two parachute-cord guys are snapped into a hardware ring which is slipped over the top hose clamp. The loose ring allows the mast to be rotated within the bottom outside section of tubing to aim the beam. The guys are secured to the opposite side of the automobile by stretch cords hooked into loops in the guys at one end and under the fenders at the other.

The storage box was made by removing all the staples on the side and end flaps of the antenna shipping carton. The corners were reinforced with pieces of cardboard and the ends were closed with duct tape. The carton is thus converted to a long box with a hinged top cover. The box can be kept closed with a large rubber band around each end.

Setup Procedure

The following procedure has been worked out for mounting the beam and erecting the mast on a 1977 Oldsmobile Delta 88.

Prior to field operation, the mast should be erected without the beam to adjust the length of the guys. (See "Field Operation," below.) With the mast extended so that there is a 10" overlap of the first and second sections (the first section consists of the 1-1/8" and 1" pieces telescoped) and the top section is extended to just uncover the market hole (mast height 12 ft.), fasten each guy to a 35" stretch cord and hook one cord on each fender on the side of the auto opposite to the mast.

The rear guy should be hooked at the rear of the wheel to let the guy clear the rear door. Adjust the length of the guys to provide snug guying but not so as to bend the mast. For future rapid setup in the field, tie an overhand knot in a bight in the cords to provide a fixed loop to take the hooks on the stretch cords. Tie a recognizable knot or otherwise mark one cord to distinguish which cord goes to which fender.

Field Operation

1) Remove the telescoped mast, the stretch cords, and guy lines from the storage box. Hold the telescoped mast vertically against the side of the auto in the space between the doors (a stiff section of the frame as opposed to the more flexible door panels). A cloth pad between the mast and the side of the car will protect the finish. Near the bottom, take one turn with the short stretch cord around the mast and hook it onto the underside of the frame. Take one turn around the top of the first section of the mast with one of the long stretch cords and hook it onto the roof gutter. The mast will now be held firmly against the side of the car. The cords are just the right length for the Delta 88, but different lengths may be required for other models.

2) Loosen the top two hose clamps. Slide the hard-

Piece	Diameter	Length	End Slot
1	1-1/8"	53"	1"
2	1"	55"	1"
3	7/8"	56"	1"
4	3/4"	56½"	none

Table 1.

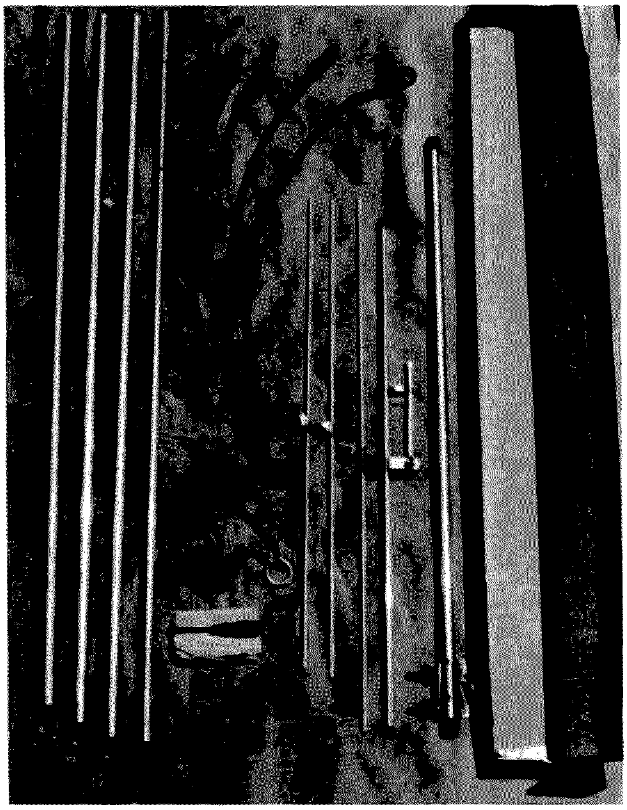

Photo E. Pictorial parts "list." (See Parts List.) The box on right is storage box made from the beam antenna shipping carton.

Parts List

1	Cushcraft A147-4, 4-element, 2-meter antenna
4	8-32 wing nuts
2	1/4" wing nuts
10	flat washers for 1/4" U-bolt (about 5/16" spacer on each leg of U-bolt)
4	6-ft. lengths, .058"-wall, 6061-T6 aluminum tubing (see Table 1)
3	stainless-steel hose clamps
1	1-1/2" hardware ring
2	small snap hooks, size to fit hardware ring
2	nylon parachute cords or other small lines about 12 ft. long (cord smaller than about 3/16" is not convenient to handle during mast erection)
3	stretch cords with hooks, overall length 35" to ends of hooks*
1	stretch cord with hooks, overall length 28" to ends of hooks*
1	wood base, approximately 3" x 6" x 5/8" thick (for mast base on unpaved surface)
Tool	spin-tite or end-wrench to fit hose clamps

Total weight in storage box—7¾ lb.

*These are standard sizes at the local hardware store.

ware ring over the top section of the mast Fasten both hooks onto the ring and throw the two guy lines over the roof of the car. Raise the top mast section about a foot and secure it by tightening the hose clamp.

3) Remove the antenna boom and elements from the storage box and assemble them. Mount the antenna on the top section of the mast and snug the U-bolt by tightening the wing nuts. Connect the coax transmission line to the antenna.

4) Raise the top section of the mast to just uncover the marking hole and fasten it securely by tightening the hose clamp.

5) Extend the middle section so the total height is about ten feet. *Hold the middle section up firmly with one hand and fully tighten the hose clamp. Stand so as to not be under the antenna.* Hook the two remaining stretch cords to the guys and hook the cords under the fenders. While holding the middle section with one hand, carefully extend it until the two guys are pulled up taut but not so as to bend the mast. *Tighten the hose clamp fully.*

6) Loosen the hose clamp at the bottom—the one around the 1-1/8" bottom tube. Aim the antenna in the desired direction by rotating the mast within the 1-1/8" section. Tighten the hose clamp.

7) Pass the coax feedline from the antenna into the car and plug it into the two-meter rig.

You're in business.

CAUTION: Do not erect the mast in any location where it could possibly contact electric wires. Use care when handling the mast with the beam installed. If the sections inadvertently telescope, the antenna elements can become lethal spears.

To take the antenna installation down, hold the mast section being lowered *firmly in one hand*, loosen the hose clamp on that section, and then ease *it down with both hands*. Do not let the elements hit into the car roof—very hard on the finish.

The installation described is stable and adequate for limited periods in moderate weather. The erected mast could be strengthened for a longer stay in windy weather by adding a third guy opposite the other two, tied to a cinder block.

One disadvantage of this setup is that when in place, neither door on one side of the car can be opened. This makes it awkward for two people in the front seat. It will probably be most convenient to mount the mast on the driver's side and use the opposite side as the operating position. It is also not convenient to rotate the mast from inside the car. However, the four-element beam has a broad lobe, so it need not be pointed precisely.

Performance

With nothing resembling an antenna range or controlled field-strength measurements, an attempt has been made to compare the performance of the beam with that of a 5/8-wavelength mag-mount roof antenna. The equipment used consisted of an Azden PCS-3000 FM transceiver and a coax antenna switch to allow rapid antenna transfer. The PCS-3000 has an LED S-meter. In order to obtain comparative measurements, the incremental signal strength in dB was predetermined for each of the LEDs.

The signal from several repeaters indicated a beam gain of from 10 to 12 dB over the rooftop antenna. One distant repeater that could not be heard on the rooftop antenna was activated with the beam. A simplex test with a station 17 miles distant indicated approximately a 10-dB advantage for the beam on both transmit and receive. With five Watts of output, the signal at the distant station was reported weak and noisy. With the beam, the report was "solid, noise-free copy."

The mast and beam arrangement has proven to be a convenient means of quickly making a significant improvement in communications performance from an automobile in a fixed location.■

Simple Parabolic Theory

With a little bit of math—presented here—you can understand, design, build, and enjoy these effective antennas. Hopefully.

Luis E. Suarez OA4KO/YV5
PO Box 66994
Caracas 1061-A
Venezuela

In the near future, radio amateurs will be exploring new horizons that will dramatically enlarge the panorama of our radio activities. High-altitude satellites and frequencies above 1 GHz will be used along with very sophisticated transmitting modes. In contrast, most radio amateurs are reluctant to undertake any project at frequencies above VHF, mostly because of lack of easy-to-read literature. This article is intended to clarify some concepts on parabolic antennas, to help in filling the gap in this area.

The subject is centered on the theory of parabolas and their behavior. The design of reflectors is discussed with a minimum of mathematical implication.

What Is a Parabola?

The parabola (paraboloid of revolution) is a curve that theoretically is generated by a point which moves in such a way that its distance from a fixed point, called the focus, always equals its distance from a fixed line, called the directrix. In Fig. 1, D-D′ is the imaginary line called the directrix. C-C′ is the axis of the parabola; it is perpendicular to the directrix. The moving point is P′. If E-P′ = P′-F for any position of P′, then P′ is moving along a parabolic curve. P is midway between directrix D-D′ and focus point F.

If the parabola is rotated around its axis, a surface called the surface of revolution is produced. The same properties of the paraboloid of revolution apply for all the surface of revolution, because of symmetry.

Energy Reflection

It is important to know how reflection is produced in a plane in order to understand how the parabolic antenna works. In the next paragraph, I'll explain how the reflection of a light beam is produced. The same criterion should be employed when the energy source is a radio antenna.

In Fig. 2, you see a light beam that is aimed against a polished surface (like a mirror) from point O to point B. The beam will reach point B with an incidence angle α. A reflection B-A will be produced and reflection angle β will be equal to incidence angle α.

Similarly, in a parabola (see Fig. 1), if a tangent to the curve is drawn at any point P1, then the angle α equals angle β. Thus, if a source of energy is placed at focus point F, its beam is reflected by the parabola surface at point P1 in the direction P1-L. Since P1-L is perpendicular to D-D′, it is also parallel to axis C-C′. The same is valid for all points in the parabola. Thus, a sharp directional beam may be

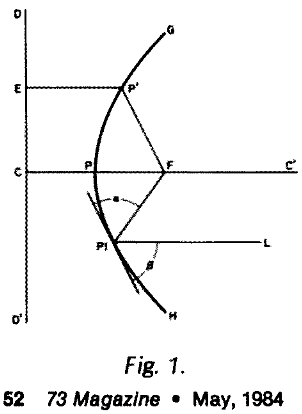

Fig. 1.

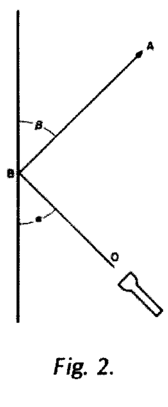

Fig. 2.

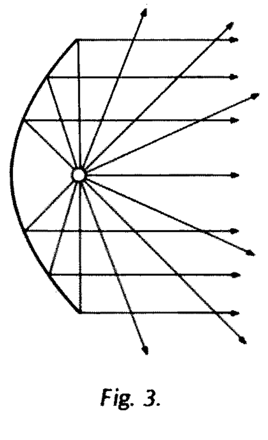

Fig. 3.

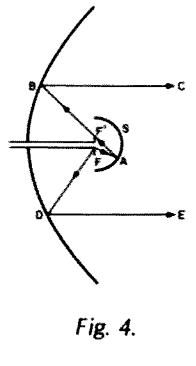

Fig. 4.

obtained from a small nondirectional source. But besides the reflected beam, there is also present a diverging beam radiated directly from the source. See Fig. 3. Hence, the resultant wave has considerable scattering unless the source is made directional.

You should be aware that the theoretical source point has no physical dimensions but is spherical in essence. And that a dipole is generally used in practical parabolics and obviously not all parts of the dipole are at focus although most radiation is produced at its center. Thus, defocusing is minimized. The higher the frequency, the smaller the feeding and the better the focusing.

Second Reflector

To eliminate the formed divergency beam, a second reflector is used. See Fig. 4. It is a spherical shield, S, mounted surrounding the dipole. It is not parabolic; it is spherical. The shield reflects radiation F-A back to point B. From B, it is finally reflected in the direction B-C. The energy that does not reach the shield will follow the normal path F-D-E as shown in the figure.

The shield should be large enough to surround the dipole and small enough to not obstruct the normal energy path. The shield should have a radius of a value λ/2 or a multiple of this value. The energy leaving the dipole in the axial direction will be canceled, but this has no importance since most of the energy will make appreciable angle with the axis.

The shield or second reflector actually produces reinforcement because the beam is reflected at A with a 180-degree phase reversal. The total path from F to A and F′ corresponds to

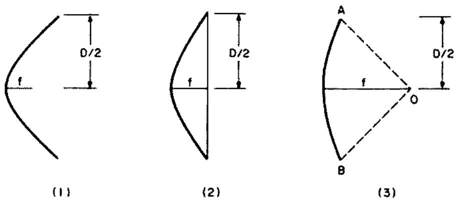

Fig. 5.

a phase reversal of 360 degrees. This, plus the 180 degrees from reflection, makes the beam returning along A-B 180 degrees out of phase, thus producing gain.

Instead of the second reflector, a three- or four-element beam could be used with the beam front aimed against the parabola. It is a practical approach for 23 cm and 70 cm but not feasible for microwaves, since horns are much more suitable at millimetric waves.

Size of Parabolics

The parabolic reflector is specified by its diameter and the focal distance. In Fig. 5, three types of parabolas with the same diameter and different focal distances are shown. Parabola 2 has the property that f = D/4 and parabola 3 uses a directional feed that confines the beam within the angle A-O-B. In this case the shield is certainly not necessary, since very little energy is radiated back from a high-gain antenna. Of course, the antenna is placed so that the beam is aimed against the parabola. In the case of parabola 1, the feeding should not be a directional antenna since the beam would not illuminate the whole reflector, with the consequence of loss of gain. In the case of parabola 3, if a dipole is used, scattering of signal is expected beyond the reflector edge. It is noteworthy that the feed antenna's gain is consequence of the directivity and has no meaning in the overall gain of the parabolic.

It should be noted that for a dipole (Fig. 4), radiation-lobe angle in the plane of the paper is greater than in the plane perpendicular to it. This means that the radiation pattern is not conical. If the dipole is vertically mounted, then the vertical angle will be wider than the horizontal angle. It is expected to be 1.25 times greater.

It is of paramount importance that the beamwidth of the feed be matched with the aperture angle of the parabola as seen from the feed. To determine the distance (f) from the focus point to the parabola vertex (P in Fig. 1), use the formula: $f = D^2/16d$, where D = parabola diameter and d = parabola depth (F-P in Fig. 1). For parabola 2 in Fig. 5, the distance f = parabola depth d. But for parabola 3, the distance f is greater than the parabola depth.

Cassegrain Parabolic

The feeding of parabolics is often a cause of divergence or energy scattering that produces undesirable side lobes. The feed structure blocks portions of the parabola and the energy reflected back to the energy source creates standing waves. The above problem, of course, is worse in mi-

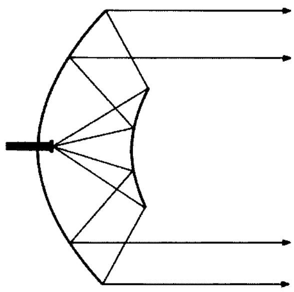

Fig. 6.

crowave parabolics that use bulky feedhorns. This is the case when maser or parametric amplifiers are placed very close to the feed. To avoid this problem, a technique known as Cassegrain is used. Cassegrain parabolics are fed from behind the parabola. See Fig. 6.

The main disadvantage of this type of feeding is the aperture blocking introduced by the hyperbolic subreflector used to reflect the energy back against the parabola. To overcome this problem, the feed is extended and the subreflector is reduced in size.

Parabolic Gain

The gain of a parabolic depends on its size. Any parabolic antenna may be used at any frequency as long as the feed system (dipole or whatever) is resonant at the chosen operating frequency. The gain is greater when the frequency becomes higher or the parabolic diameter becomes larger. The most important consideration is that the feed should entirely illuminate the surface of the parabola. The efficiency of the para-

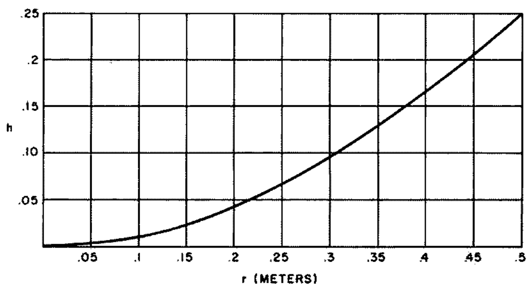

Fig. 7.

	Dish Diameter in Meters					
Band	**1**	**3**	**6**	**10**	**20**	**45**

1.25	5.4	15	21	25	31	38
0.7	10	20	26	30	36	40
0.23	20	30	36	40	46	53

Table 1.

bolic may be considered as 55%. Thus: gain over isotropic = .55($\pi\times$diameter/wavelength)^2. The parabolic beamwidth is calculated as follows: beamwidth = 137.5/(D/wavelength), where D = parabola diameter.

Designing a Parabolic Antenna for 23 Cm

Now, let's design a parabolic antenna for 23 cm using a parabolic reflector of 1 meter in diameter. This antenna could be used to work AMSAT Phase III mode L. The gain will be: .55[3.1416(1/.23)]^2 = 102; dB gain = 10 log (gain) = 20 dBi.

If a second reflector is used, then the power gain is quadrupled: 4 × 102 = 408. The dB gain will be increased by 6 dB: dBi gain = 10 log (408) = 26 dBi. −1 to −3 dB should be expected in actual construction.

Reflector Design

The parabolic beamwidth is calculated as follows: beamwidth = 137.5/(D/wavelength) = 31 degrees, where D = parabola diameter.

From the preceding discussion, it is known that the focal length should equal D/4 or 0.25 meters. Then the shape of the parabola is plotted on graph paper from the following equation: $h=r^2/4f = r^2/D$, where h and r are the axial and perpendicular distances in meters to any point P on the parabola. See Fig. 7. For our parabolic, D=1 meter.

The curve is then plotted by calculating various values of r as shown in Fig. 7. This way a template is constructed to which the parabola may be fabricated.

Mechanical Considerations

Any irregularity in the reflector tends to defocus the beam, increasing the side lobes and reducing both the gain and the beamwidth. The more the surface error, the more the ill effect. A surface error of up to 1/16 wavelength is tolerable. 1/16 wavelength at 70 cm is 4.38 cm and at 23 cm is 1.44 cm. So, at 70 or 23 cm it is very easy to achieve such tolerance. However, this tolerance is proportional to the reflector diameter. A 10-meter reflector would be expected to have surface defects 10 times greater than for a 1-meter reflector. Thus, the smaller the reflector, the more careful its construction should be.

Finally, it is worth mentioning that the lowest practical frequency limit for this kind of antenna is around 100 MHz. Below this frequency, the feed system and the gain-to-diameter ratio are far from desirable.

Table 1 shows the gains (dBi) achieved with several dish diameters for the amateur bands from 6m to 23 cm. In the table you will see that 20 Watts into a parabola of 1 meter (3 ft.) will allow you to reach Phase III mode L with the limit of 2 kW erp, not considering feedline losses. The 6-meter band is shown just for comparison purposes.■

Control Your Mobile Power

Can commuting be a daily QSO party?
Yes, with this no-payment installment plan.

Bradley G. Mauger KB5QZ
48 F Ridge Road
Greenbelt MD 20770

Mobile operation is one of the most efficient uses of time possible. It allows me and, I am sure, many other amateurs to squeeze some operating into an otherwise too busy day. Almost all solid-state transceivers for any amateur band have been designed with operating mobile in mind and can be powered directly from an automobile's 13.8-volt power system.

Improper care in connecting amateur equipment to this power can cause problems, however, and, in some cases, even damage equipment. No one would knowingly try to operate a 13.8-volt radio from an eight-volt supply or from a supply that had 24-volt spikes on it. But low-voltage conditions can easily occur by having resistance in the circuit used to deliver power to the radio. Many high-power transceivers draw in excess of fifteen Amps while transmitting. Under these conditions, a few tenths of an Ohm can easily drop the supply voltage a few volts. A good, direct path from the battery to the radio should be made to ensure a steady supply voltage. This connection should also be fused for safety.

The assembled power controller mounted on the wheelwell in the engine compartment of my car. The relay is held to the plastic sandwich box with double-sided tape, the capacitor is held with a cable tie, and the box is held in place with a single sheet-metal screw which also is the ground point for the relay and capacitor.

When we start our cars, nasty things happen to the power system. For one thing, it gets loaded down by the starter's high current demand. The starter, while grinding away to start the engine, can induce huge pulses onto the car's power system. These high-voltage pulses can kill solid-state devices.

The Solution

Automobile manufacturers protect their radios and accessories from these starting transients by having a relay or switch connected to the ignition switch that disconnects power from these accessories while the engine is being started. This is why the radio turns off when the car is being started.

The circuit in Fig. 1 is a power-control system I use in my mobile operation. It uses the accessory voltage, which is disconnected automatically during starting, to operate a relay. Only when accessory voltage is present will power be supplied to the amateur gear. The capacitor helps filter out any residual noise and alternator whine.

Other than the accessory voltage wire to the relay coil, all wiring should be #14 or #12 stranded wire. Suitable wire can be found in the automotive department of most department stores.

Finding a place to put the circuit can be a difficulty, especially in today's smaller cars. I built mine into a soft-plastic sandwich box and bolted it onto the fender inside the engine compartment. Wires enter the box through tight-fitting holes. I mounted the fuse holder through a hole in the side where it would be handy and mounted the relay and capacitor to the box with double-sided tape. Fig. 2 shows the layout of my box, although most any layout would work.

Finding the Voltages

The 13.8 volts coming from the battery should be obtained as close to the battery as possible. Most cars have two leads on the positive terminal, a fat one that goes only to the starter and a thinner one, about a quarter inch in diameter,

that goes to everything else. This thinner one generally goes to a terminal block or a relay. Solder a large terminal lug to the input lead of the power controller and fasten this lug to the same post or connection that the thin battery wire is connected to. Some amateurs connect leads directly to the battery, but because of the corrosive conditions close to the battery, these connections can corrode and lose their good connection.

Finding the proper accessory voltage to operate the relay varies in difficulty from car to car. In my car, the positive wire from the radio was readily available under the dash, so I tapped into the line with a "squeeze" tap connector (Radio Shack 64-3052). If your car does not have a radio or if the radio's power lead is not available under the dash, the power leads of any accessory which automatically turns off during starting will be suitable (e.g., windshield wipers or heater fan). Otherwise, check around the fuse box for such a voltage. Even if your car has no radio, it usually has a fuse dedicated to accessories, and it might even be marked so. Whatever you find, be sure to check the voltage to make sure that it goes away when the starter is engaged.

Most cars have plastic or rubber plugs in the firewall. In order to pass wires from the engine compartment to the passenger compartment, I drill holes in these plugs. Try to make the holes no larger than necessary so that fumes from the engine compartment don't get into the passenger compartment.

Grounding

Even if you have a good, solid connection to the positive terminal of the battery, losses can be experienced in the ground or

The power controller, sealed in the plastic box, takes little room in the engine compartment and keeps the electronics safe, clean, and dry.

negative side of the circuit. In a car, the negative leg of the circuit is usually the car, its frame, and the body. This is not always sufficient, especially in newer cars.

In order to insulate the cars against sound and to eliminate squeaks and rattles, manufacturers put sound-deadening insulation between metal parts. This material is usually also an electrical insulator. Any current flowing between body parts must then travel though the bolts and screws holding the parts together. These often rust and lose their good connections.

I found this out accidentally by an experience I had with my car. I was having problems keeping a battery charged and had already replaced the battery and solid-state voltage regulator—which was fas-

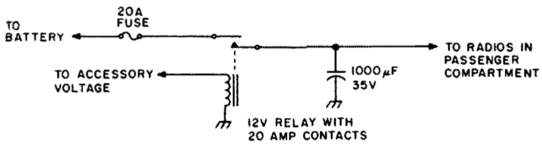

Fig. 1. Schematic of the power-control·box. The capacitor value is not critical, but should not be increased since it would increase the current surge through the relay.

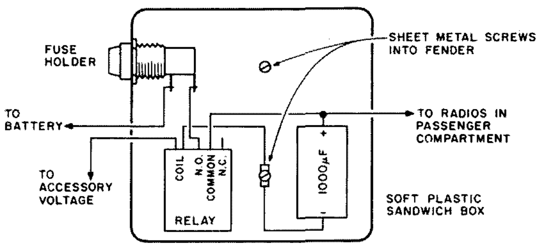

Fig. 2. The power control box as built into a soft-plastic sandwich box. The fuse holder is Radio Shack 270-367, the capacitor is 272-1019, and the relay is 275-218 with the common and normally-open contacts tied in parallel for increased current. The normally-closed contacts are not used.

tened to the fender in the engine compartment. My alternator checked out OK.

One day, after complaining to a mechanic friend, he took his voltmeter out of his toolbox and put the leads between the cases of the alternator and voltage regulator. The meter showed that, while the engine was running, there was over a volt difference between these two grounds. The ground connection of the voltage regulator had so much resistance that it was keeping my battery from being fully charged.

Placing a jumper wire between the alternator and the regulator fixed my low-battery problem. The moral of the story is: Don't trust grounds! Run a good stout ground line from the point the battery's negative terminal connects to the car (usually the engine block) into the passenger compartment, and ground all your equipment.

Temporary Installations

Sometimes it is not possible to make a permanent installation, as in a borrowed or rented car, for example, or in the spouse's car if your spouse doesn't share your enthusiasm for amateur radio. (My XYL, Mary, has little appreciation for a car full of radios, wires, and connectors. After years of explaining and demonstrating the pleasures of operating and construction, she still calls it CB just to irritate me.) However, generally cars have a cigarette lighter, and a cigarette-lighter adapter is available cheaply that can supply power in a pinch (Radio Shack 270-1534, for example). For VHF and above, magnetic-mount antennas provide a good means of temporarily connecting an antenna.

I have found that it is not a good practice to leave radios sliding around loose on the seat or floor while

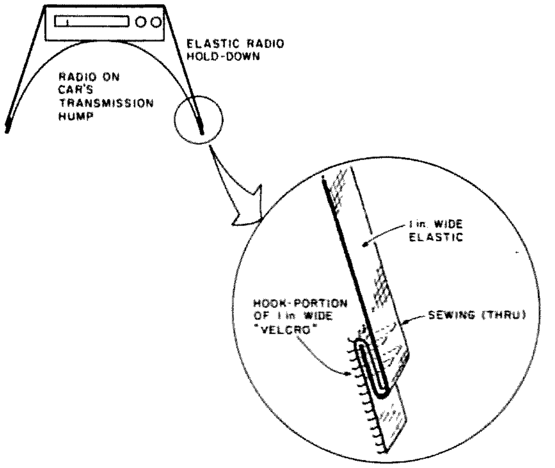

Fig. 3. An example of a radio mounted to the transmission hump with an elastic hold-down. The radio could be mounted on the side of the hump for better viewing. The insert shows the construction of one end of the hold-down.

driving. The device shown in Fig. 3 (which my wife refers to as my "bra-strap") can hold a rig firmly to the floor or to the transmission hump. I also use them to hold amplifiers and other accessories to the transmission hump of my car. It consists of the hook portion of a one-inch-wide piece of Velcro fastener sewn to both ends of an eighteen-inch length of inch-wide elastic. The hooks grab firmly into the carpet but can be peeled back off in less than a second. Black elastic and Velcro give a nice, professional look, but any color works.

Mounting Radios

A big problem with any mobile installation is that radios should be easy to disconnect and remove from vehicles. A locked door will discourage only a casual thief. I use a two-part mount that is sold for mounting car stereos. These are available at discount houses often for less than five dollars apiece. I bought six identical mounts so that I could mount all my rigs (and have a few spares, of course). I have two mounts in my car and have the remainder bolted to a short bookshelf in my shack. On the radio half of the mounts, I have mounted a ten-meter FM rig, a two-meter rig, a CB, and a cassette deck. Now all my radios fit interchangeably, and it takes only seconds to install or remove gear.

All my antennas have BNC connectors on them and all rigs have adapters to BNC connectors. This helps save time and keeps everything standardized.

The mounts I use have six sliding contacts. I currently use only two, one for power and one for ground, but I plan to use the others for external speakers and a remote mike.

Mobile operation can be a lot of fun, especially if time is spent on a good installation. This includes having good power and ground connections. In any case, try not to leave radios turned on while starting, and *never* transmit while starting. Hope to meet you soon on the air, mobile. ■

Virginia's Antenna Farmer

From Falls Church comes a simple message to fallow hams: Simple antennas work!

Bill Clarke WA4BLC
Box 2403
Falls Church VA 22042

This is not just another innovative antenna article. I haven't reinvented the wheel and I shall not ask you to do mind exercises to understand obscure theory, nor shall I dazzle you with exotic physical design. I shall, however, provide the weekend "antenna farmer" with a simple-to-construct, surefire antenna project.

Most new-generation solid-state HF transceivers are designed for instant QSY but suffer severe swr limitations. Hence the need for broadbanded antennas that require no tuning or switching to QSY from band to band.

The antenna I shall describe is fail-safe, will work under even adverse conditions, and has no lossy coils, traps, or stubs. Best of all, it can be designed for any band or bands desired, fed with one feedline, and built in a few hours for only a few dollars.

Theory

The dipole antenna and various like antennas have been around for a long time. They are the workhorses of most antenna systems, although often hidden within complex design. The dipole is inherently balanced, broadbanded, and easily fed with coaxial cable. It works well on the lower amateur frequencies, giving good general coverage in all directions. It also is quite useful on 20 meters and above but does display some directional characteristics.

Many amateurs, capitalizing upon these characteristics plus the facts that dipoles are light in weight, inexpensive, and easy to install, have never felt a need for towers or directional antennas. Yet these same hams have worked WAS, 5BWAS, DXCC, etc.

Materials

First, before building the antenna, you must have a feedline to carry the rf from the transmitter to the antenna. I've found, over many years as a ham, that feedlines must reach from the transmitter to the antenna. No more, no less. Excess will only get in the way, and less won't reach. I've never found a need for quarter-wavelength or other measured feedlines.

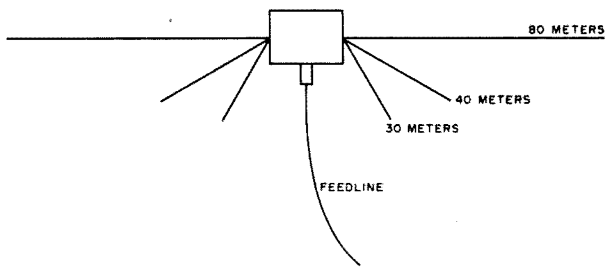

Fig. 1. Typical 3-band antenna with one feedline.

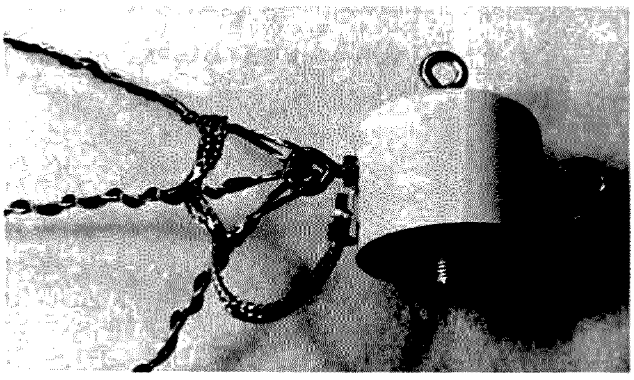

The center insulator with the left side of a 3-band antenna installed. Notice the use of the braid as a flexible connector line from the antenna itself to the center insulator lug.

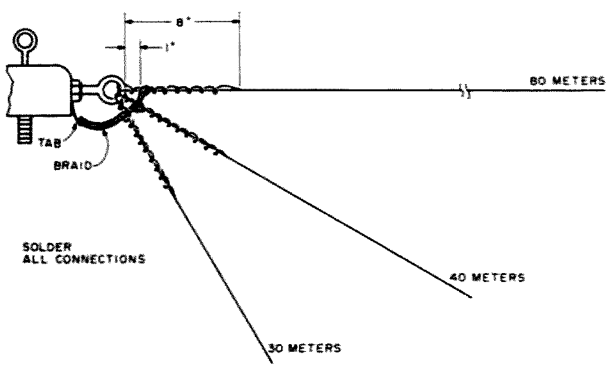

Fig. 2. Connection of legs to the center insulator.

The feedline should be RG-58 for output levels under 200 Watts and RG-8 for all others. At frequencies from 160 to 10 meters, these choices will function well and exhibit negligible losses (see Table 1).

Purchase your coaxial cable carefully; if good quality is purchased, you can be assured many years of use. Check the cable for the amount of shielding over the center conductor. Generally, the more shielding, the better the quality. To cut cost corners at this point is to invite trouble in later years with a poorly performing station.

Be sure the PL-259 connectors used on your feedline are installed properly. If in doubt, consult any of the handbooks for examples and guides on their proper installation.

It is a wise amateur who covers his outdoor feedline connectors with a weatherproof sealant. I generally use a silicone glue such as General Electric's RTV product. This will prevent moisture from entering your carefully purchased coaxial cable and avoid the moisture-associated problems of rf loss and high swr, both of which will affect your operation.

The wire for the antenna should be copper, stranded or solid, number 14 or larger, to ensure adequate strength. An alternative, used at this station for years, is galvanized electric fence wire. The latter is available in rolls of ½ mile, size #17, for about $15. You also will need a few insulators, some nylon or poly rope, and a center insulator. I recommend the Van Gorden Engineering HI-Q, at $6.95, available from most amateur outlets.

Construction

Table 2 gives the lengths of legs for the various bands of operation. The lengths noted are the distance from the center insulator to the end insulator for each leg. I recommend building this antenna for two to four bands. More than this will result in a clumsy package to handle and install (see Fig. 1).

In constructing your antenna, each leg must be strongly fastened to the center insulator, then soldered to the tab. I have found that a jumper wire from the leg to the tab is the best method, as it allows for flexibility during adverse weather conditions (see Fig. 2).

Each leg must pass through the eye of the center insulator and fold back eight inches. The eight inches is wrapped over the leg itself and soldered. After all legs have been installed in this manner, cut a piece of RG-58 six inches long and strip the braid off. Use this braid as the jumper, wrapping it once around each leg about one inch from the eye, leaving one inch free between each leg and soldering same to each leg. Then solder the free end to the tab.

Installation

When construction is completed, you must decide the method of installation—dipole or inverted vee. For inverted vees, the angle between the legs at the apex must never be less than ninety degrees or signal cancellation will result. A height of thirty feet at the apex will be adequate for most general operation. If a dipole is decided upon, the height should be equivalent to the apex of the vee—thirty feet or better.

The longest legs are the highest. All legs must be kept sufficiently above ground level so as to avoid having a shock hazard.

The antenna I use has legs marked with a single asterisk in Table 2 and is operated as an inverted vee. The height of the apex is thirty-five feet, fastened in a handy tree. All legs of my antenna end with a small plastic insulator and are tied to a support at least eight feet above ground level. This keeps the kiddies from coming into contact with the wires.

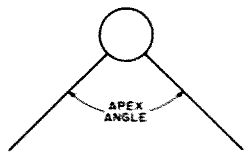

Fig. 3. Apex angle.

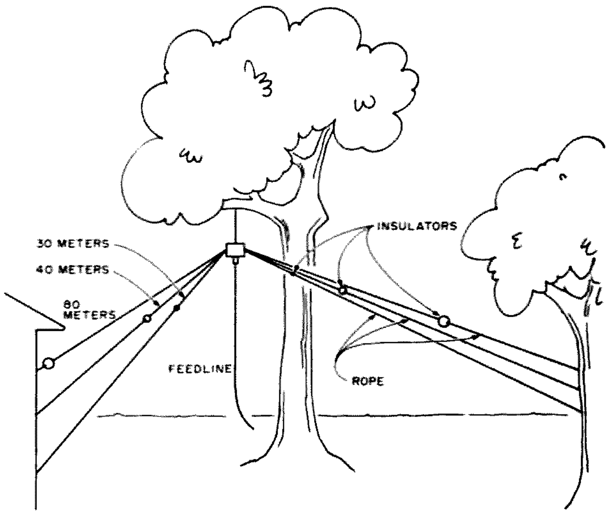

Fig. 4(a). Typical inverted-vee installation.

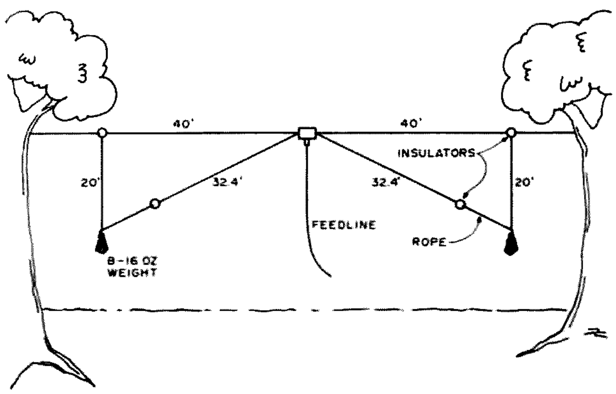

Fig. 5. Alternative design for limited space.

Band	RG-58	RG-8
160	.50 dB	.25 dB
80	.75 dB	.40 dB
40	1.00 dB	.55 dB
30	1.25 dB	.65 dB
20	1.50 dB	.80 dB
15	1.80 dB	.95 dB
10	2.50 dB	1.20 dB

As interpreted from the *ARRL Antenna Handbook.*

Table 1. Transmission line losses.

The feedline should be allowed to fall straight down from the center insulator, then led to the station. Try to align the feedline and the various legs to prevent the feedline from running parallel with any of them (see Figs. 3 and 4).

Testing

After the antenna is assembled and is in position, test it on each band and note the swr at the design frequencies. If the swr is 1.2:1 or less, you need no further adjustments. Should the swr exceed this limit, tune up the band 100 kHz and note the swr, then tune down 100 kHz and note that swr. If the swr is lower *up* 100 kHz, you must increase the length of the legs being tested. If the swr is lower *down* 100 kHz, decrease the length. The adjustments in length must be made equally to each leg of the band being tested or there will be a loss of symmetry. Use adjustment increments of six inches for 160 meters, three inches for 80, two inches for 40 and 30, and one inch for all other bands. Always test and adjust the lowest frequency band first, as this set of legs will be the support for the rest of the antenna.

Alternative Design

An alternative design that will allow operation on 80 and 40 meters in a limited space is built in a similar fashion, but the longest legs, those for 80 meters, are folded and the shorter legs are nested within them (see Fig. 5). This antenna has been a favorite of mine for many years and has given performance equal to any full-size antenna tried at this QTH. Be sure to keep the leg ends at least eight feet above ground level to avoid shock hazard. On the diagram you will notice weights on the ends of the folded legs; these are to keep tension on the wires and keep them straight.

Conclusion

These antennas give instant QSY for all bands of design with no need for an antenna tuner, which was the original goal, and will provide consistently good contacts. I have worked all states on 80 and 40 meters with these antennas, again attesting to the fact that simple antennas do work, and work well.

Remember safety and keep your antennas clear of all power lines. Happy "antenna farming."■

Band	Length in feet	Length in meters
160 low	126.5	38.6
160 high	120.0	36.6

Throw in TV

Why not? This helix-building experience includes everything else. . .

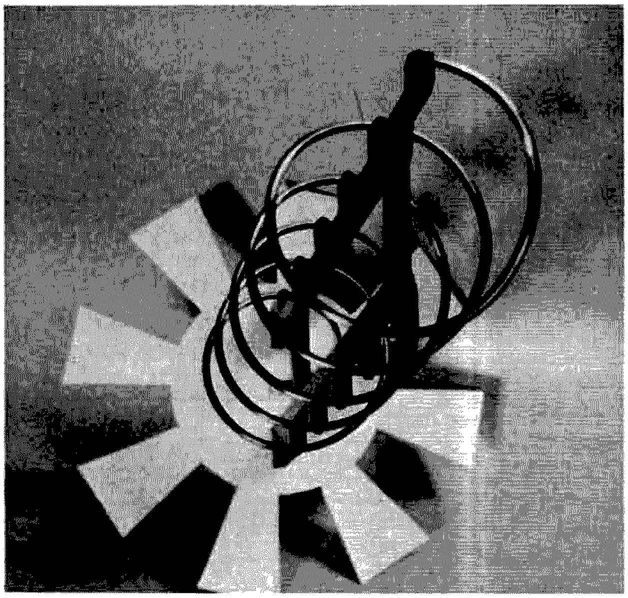
One of the major complaints made by radio amateurs is the lack of time for working on amateur-radio projects. Such things as mowing the lawn, painting the house, and gardening are brought up by the wife just when some time or a break in the weather is found for an antenna or other construction project. One solution I attempted was to mix my projects between those for the family and those for amateur radio.

For instance, recently I wanted to build a new antenna to receive OSCAR on 432 MHz. The antenna would be a helix. Helixes are circularly polarized and will reduce fading due to polarization rotation. However, I planned instead to build two antennas—both helical. The first would be for UHF television reception. It would be used to pull in channel 15 for the family television. Because of the wide bandwidth of the helix, reception of channels 27 and 33 would also be improved. The first antenna would serve as a prototype for the second, a satellite antenna. The second antenna was the one I wanted.

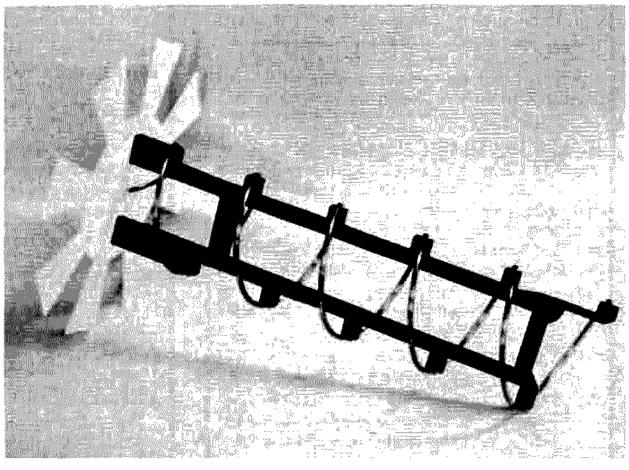
Design

The design of a helix antenna is straightforward and detailed methods can be found in the literature.[1-3] However, for amateur and entertainment applications, a few simple rules suffice.

First, the circumference of one turn should be between 0.75 and 1.33 wavelengths. For use on a single frequency, a value of 1.0 is used. For the television antenna, I chose a center frequency of 610 MHz. Hence, the circumference of one turn is: C = 300/f(MHz), 300/610 = .49 meters or 19.4 inches. The low-frequency limit is then found by: $\lambda_L = 1.33 \times .49 = .654$m; $f_L = 300/.654 = 459$ MHz. The high-frequency limit is found by: $\lambda_H = 0.75 \times .49 = .369$m; $f_H = 300/.369 = 813$ MHz. The UHF television band extends from 470 MHz to 890 MHz.



End view of finished 5-turn helix for UHF TV reception.



Side view of UHF TV helical antenna. The antenna is right circularly polarized.

	METRIC	ENGLISH
S	.114m	4.5"
d	.152m	6.0"
D	.393m	15.5" (16" USED)
α	13.5°	13.5°

Fig. 1. Five-turn right-circularly-polarized helix antenna.

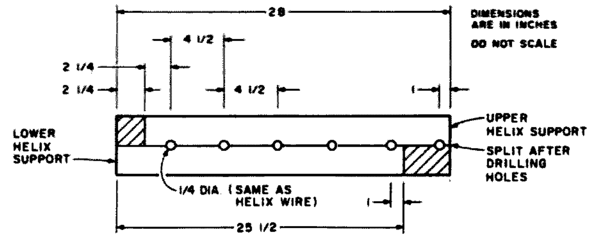


Fig. 2. Longeron construction.

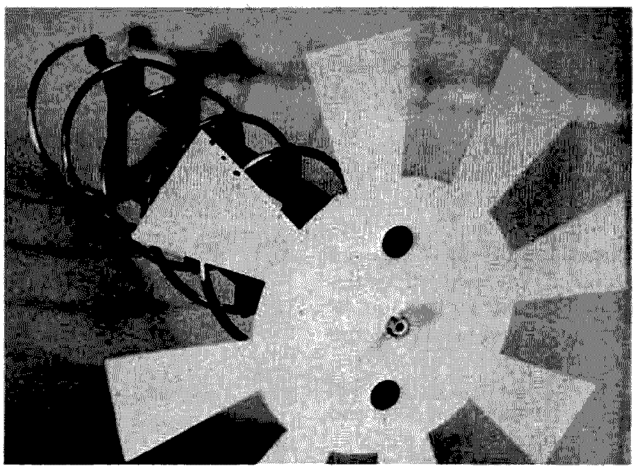
Since our area is restricted to channel 49 or lower, the design is complete. I believe the antenna would work even for higher channels, but you can shift the center frequency to redesign for the higher channels if desired.

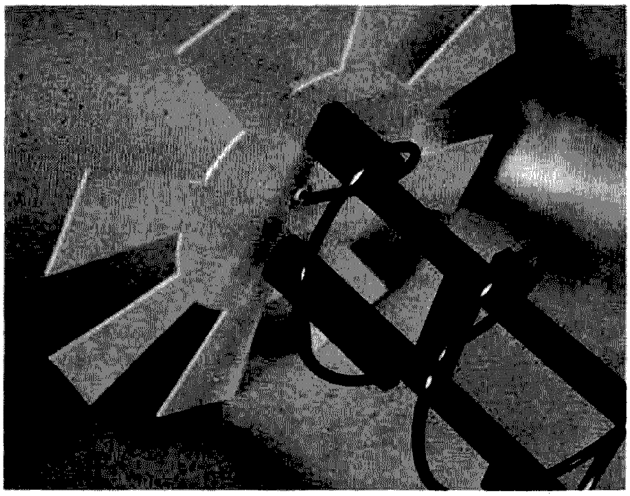
Second, the pitch angle for the helix should be between 12 and 15 degrees. I used a value of 13.5 degrees. Knowing the pitch angle (α) and the circumference (C), the turn diameter (d) and the turn spacing (S) are calculated as follows: $d=(C/\pi)\cos\alpha=(.49m/3.14)\cos 13.5=.152$ meters $=6$ inches. $S=C\sin\alpha=.49m\sin 13.5=.114$ meters $=4.5$ inches.

Third, the ground plane or disk diameter, D, should be equal to or exceed .8 wavelengths at the design frequency: $D \geqslant 240/f(MHz)=240/610=.393$ meters $=15.5$ inches (round up to 16 inches).

The final dimensional values are shown in Fig. 1. The diameter of the wire used to wind the helix should be between .005 and .05 wavelengths. For the television antenna, this translates to between 2.45 and 24.5 mm (0.096 and 0.96 inches). Quarter-inch copper tubing works well and looks impressive when cleaned and protected with clear lacquer. How much tubing is needed? Simply multiply C by the number of turns plus one to allow for the start. In this case: $L=C(5+1)=2.94$ meters or about 9 feet 8 inches. Hence, two antennas could be made easily from one 25-foot roll of tubing.



Rear view showing SO-239 connector and support mounting screws.



Close-up of supports and coax connector.

✔See List of Advertisers on page 114

After all, you have to buy the tubing for the family antenna. The leftover scrap will make do for your hobby antenna.

The input impedance of a helix can be approximated by: Z=140×C(circumference in wavelengths). Hence, for the television antenna, Z varies from a low of 105 Ohms to a maximum of 186 Ohms. If 93-Ohm coax is used, the vswr would not exceed 2:1, However, the impedance is seldom the nominal value and is influenced by how the first turn is made. I have found that for noncritical work, 75-Ohm coax is a reasonable compromise. For antennas used with medium- or high-power transmitters, particularly solid-state units, a matching network should be included.

Construction

The helix supports, or longerons, were made first. I was able to use a long scrap piece of phenolic material for the supports. Any insulative material could be used, i.e., dried wood, fiberglass, plastic, or bakelite. The helix supports were marked, drilled, and split from a single piece of material as shown in Fig. 2. The holes must be drilled before separating the two pieces. The two supports are separated with two spacers which were epoxied in place to maintain parallelism between the two helix supports. The helix turns sit in the half-hole notches. A round tile was used to slant the notches at 13.5 degrees. This allows the tubing to be seated all the way down. The antenna photographs show the spacers. They also show that I got carried away on the band saw and removed most of the excess material between the helix contact points. All I can say is that it does reduce wind load and weight and looks neat—but it is a lot of needless work.

Before winding the helix, the copper tubing was marked at each C/2 point to aid in accurately mounting the helix. The tubing was then close-wound over a short piece of 5½-inch tubing. If the wind is in the same sense as a right-hand-threaded bolt, the antenna will be right circularly polarized. After the coil was released, the far end was trimmed.

Next, the helix was slid over the support longerons. The trimmed far end was positioned over the last notch on the upper support and clamped, while a hand drill was used to drill through the tubing and into the support with a number 35 bit (6-32 tap size). Then the tubing was shifted over and just the hole in the tubing was drilled out with a 6-32 clear bit. The support piece was tapped and a ½-inch-long 6-32 screw was used to anchor the tubing down.

Turning the antenna over, the next C/2 mark was centered over the last notch on the lower support. As with the end, the tubing and support were drilled, the support tapped, and the two fastened together with a 6-32 screw.

This process was continued until each turn of the helix was firmly secured to the supports. The start end of the tubing was bent in a smooth curve to the centerline and cut off. The free end was drilled to accept the center pin of the coax connector.

The ground plane was cut from an old rack panel. Wire screen or hardware cloth would work well; I just happened to have this old panel which looked perfect for the job. Besides, getting rid of the panel can be considered as helping to clean the garage. Again, I got carried away on the band saw and the result is seen in the photographs. The final design functions as well as a solid disk but is lighter, has less wind resistance, and looks more interesting than a plain disk.

Mounted in the center of the ground plane is the coax connector, an SO-239. I know it is not a constant impedance connector, but it was cheap and it works OK. Anyway, I cannot seem to master the assembly of male type-N cable connectors. The two ¼-20 bolts that thread into the two helix supports and secure the ground plane to the supports are used to fasten the antenna to the mast via an aluminum angle bracket. A word of caution: If you use a chimney mount or mount near a chimney, make sure the antenna is below the chimney port. That way, the exhaust fumes, which are acidic, will bypass your work of art. The antenna will perform longer and will stay cleaner.

A short run of RG-58 connects the antenna to the balun on the television. Running twinlead to a balun at the antenna would gain a couple of dBs, but the extra gain was not needed. For my application, the secondary purpose in building the antenna was to get directivity and a little gain above the local tree line to reduce multi-path fading and flutter. The primary purpose was to buy time to work on a 432-MHz helix. While helping to install the helix, my wife noticed the gutters needed cleaning; maybe I can work on *my* antenna next month! By the way, the gain is between 9 and 11 dB over a dipole and the half-power beamwidth is about 50°. ■

Altona 3018
Victoria
Australia

After the disastrous Ash Wednesday bushfires in 1983, the Victorian State Government set up a Bushfire Review Committee and asked all the relief or emergency services that were involved to submit a report on their activities, plus recommendations for any improvements that these agencies thought would help in any future major disaster.

This, with respect to the role of WICEN (Wireless Institute Civil Emergency Network), was a case of shutting the barn door after the horse had bolted, for efforts had been made six months before the fires to clarify WICEN's position in the event of a major crisis. As a result of these discussions, WICEN was reminded of the vast improvements made in the communications equipment used by authorities in recent years, which meant that WICEN would not be needed except in circumstances such as an earthquake which "topples our antennas."

Just how much the authorities overestimated their communication capabilities in this type of disaster became tragically evident.

In light of the above, the Wireless Institute of Australia (Victorian Division) submitted to the Bushfire Review Committee a comprehensive report on the role that amateur radio, via our WICEN network, played in this emergency. As this report is too long to include in total, perhaps highlighting some of the faults we found in our operational procedure may help other overseas amateur emergency services to avoid the same problems.

Over 200 operators were mobilized or put under standby conditions during the Ash Wednesday period. Of these, only 30 were considered to have had any formal training with WICEN. In the event, the larger amateur population was pressed into service, and they performed very well.

Now to some of the problems. Where the WICEN operators were established at field stations, including relief centers, people did not know who the WICEN person was or where the WICEN camp was located.

People also did not know what was being provided or know how to use the WICEN communication network. They thought we were providing CB radio. These problems were usually solved by an explanation by the WICEN person, but a great deal of suspicion and reserve was still exhibited.

WICEN personnel were not identifiable through uniforms, badging, or identification cards. These would have made passing through road blocks and recognition at the point assigned for radio operations much easier.

WICEN control over movements of its personnel was inadequate because no formal arrangement existed with authorities and no proper provision had been made to cope with tasks which emerged. These included activities of an administrative and management nature, necessary in any well-oiled efficient operation.

Among the shortcomings of WICEN'S internal management was the fact that no formal records were kept of duty hours performed by field operators. This gave rise to situations in which personnel who had been without sleep for more than 24 hours were still volunteering for the next shift or another duty call elsewhere. Even when radio amateurs were ordered off duty, there was no way of checking that they actually did obtain rest.

The facilities at WICEN HQ were totally inadequate, basically because WICEN does not have a permanent HQ as such, with the result that operations were initiated at one radio amateur's home on Wednesday evening and subsequently an operating center was set up at another's garage/workshop which happened to have two telephone lines.

WICEN HQ operated for the first 2½ days with all meals being provided privately. On the third day, a mobile caravan was obtained from the State Emergency Services and placed in an appropriate site in a suburb of Melbourne. Here, personnel were obliged to solicit the aid of local residents in order to obtain toilet facilities, with food and drink still having to come from private sources.

Overall, the WICEN involvement was not only far from being an exercise in snappy message handling, tight net control, and efficient and accurate passing of formal messages, it was a disaster in itself. However, in terms of the provision of field communications in response to all known requests, the operation was a great success. It is considered that WICEN provided a significant contribution to the community.

I personally think that the service we are giving, as seen by others, is just as important as the service we think we are giving. Sometimes we tend to be blinded, within our own organization, by our own sense of achievement or failure.

Bearing this in mind, I feel the following letter of gratitude sent to the Victorian Division of the Wireless Institute of Australia says it all.

The Order of St. John In Australia
St. John Ambulance Brigade
Victoria District

In the wake of the devastating "Ash Wednesday" bushfires, I would like to place on record the Brigade's deep respect and appreciation for the vital communications links provided by the Wireless Institute Civil Emergency Network (WICEN).

There were many occasions during that tragic period when the Brigade's communications facilities were inadequate or rendered inoperative due to terrain peculiarities, traffic congestion, and other difficulties.

For the first time ever in a major incident of this magnitude, the Brigade was able to patch into the WICEN communication system with its own unique callsigns—VK3SJA and VK3SJB—adding a new dimension to emergency communication. The important benefits may be summarized in the following three points:

1. There were times in the field when communications difficulties were being experienced at the various control centers. These inadequacies in our own system were overcome by using the WICEN link to pass urgent messages to our own Communications Center, which was also part of the WICEN Net. In addition to this, we were able to provide more personnel in the field than would otherwise have been possible due to our limited communication facilities; this deficiency was overcome by attaching a WICEN radio operator to some of our units.

2. Perhaps the most important benefit inherent in WICEN is that it provides the ONLY inter-organization communication link in existence. Each organization has its own radio system, but none of these can inter-communicate. It's all very well to say that liaison between organizations must be carried out at headquarters level, but quite often in the field, time is of paramount importance. In our particular case, we found it extremely useful to be able to speedily liaise direct with the Red Cross, the CFA, and the Police on a number of occasions.

3. It amazes me at times out in the field just how long it takes for one organization to receive a request or a report from another organization working alongside; this is the classic inter-organizational liaison problem outlined in point 2 above. The advantage of the WICEN Net was further enforced because the Field Control Center was able to monitor WICEN traffic, and therefore: (a) the Brigade was better informed of the overall situation than would otherwise have been the case, and (b) we were able to anticipate requests for assistance from other sources and were thus organized by the time the formal request was received.

Like the Brigade, the Wireless Institute Civil Emergency Network is composed of volunteers highly trained for a specific task. The cost to the community of such a dedicated and skilled human resource is incalculable! The hours of training which amateur-radio operators put into their hobby and the wealth of experience gained "on air" would cost millions of dollars annually to emulate in a full-time service. The community at large is indeed indebted to the selfless dedication of the amateur-radio fraternity.

It is distressing in the extreme to learn that there is talk in some bureaucratic circles of limiting the ability of amateurs to pursue their hobby of communication and general experimentation by ad hoc and ill-conceived legislation in relation to antennas. Certainly a degree of sanity must prevail in regards to what protrudes into the air or hangs off a chimney! But surely the majority of amateurs are sophisticated enough to know what is socially acceptable in their neighborhood, and the rest I am certain would be only too pleased to reach a compromise.

The last thing we need is the intrusion of new legislation in what has traditionally been a self-regulating pursuit. A reasonable sprinkling of towers and antennas is a small price to ask the community to pay in return for a corps of skilled and dedicated enthusiasts who provide an unparalleled, voluntary, emergency service.

The Brigade looks forward to a long and rewarding association with the Wireless Institute in general and is always happy to accept the support and assistance of Institute members which has so readily been forthcoming in recent times.

Yours faithfully,
Michael A. Bonacci

BANGLADESH

Saif Shahid, Editor
BARL Bulletin
Bangladesh Amateur Radio League
GPO Box No. 3512

ANNUAL GENERAL MEETING

The 1983 Annual General Meeting of BARL was held on December 28, 1983. The agenda included setting up a two-member committee to make an in-depth study of the BARL constitution and suggest amendments and bylaws. The Annual General Meeting also showed satisfaction at the progress made so far regarding issuance of amateur licenses to its members.

A one-minute silence was observed to pay homage to the late Victor Clark. President Saif Shahid gave a short speech mentioning his personal experiences with Vic. His first contact with Vic was in April, 1982, during his visit to the USA. Saif Shahid was surprised at the discovery of the amount of knowledge and interest Vic had about amateur-radio affairs in Bangladesh. Saif Shahid saw Vic for the last time in Tokyo in September, 1983, while both of them were attending WARIC. Only two weeks before his death, Vic had written a letter to Saif wishing BARL all success. No doubt, amateur radio has lost one of its most respected leaders.

The committee for 1984 also was elected as follows: President, M. Saifud Dahar Shahid; General Secretary, Mahbubul Huque Khan; Treasurer, Manzoor Mannan; Members at Large, Iqbal Ahmed and Kh. Nazrul Islam.

BARL ANNUAL DINNER

The annual dinner was held on September 14, 1983, at the Hotel Sonargaon. The chief guest at the dinner was Prof. A. M. Patwary, Vice Chancellor of Bangladesh University of Engineering and Technology. Prof. Shamsuddin Ahmed, Chairman of the Department of Electrical and Electronic Engineering of BUET, also attended the dinner.

NEW IARU CONSTITUTION PROPOSED

With the objective of a modern, stronger, and more democratic IARU, a new constitution has been proposed. The proposed constitution contains seven articles, organized in a logical progression. The constitution answers the basic questions of what is the IARU, what are its objectives, and how is it organized? It also sets forth the fundamental rights, duties, and obligations of member societies. The 18 bylaws, on the other hand, provide detailed descriptions of procedure and set forth additional rights, duties, and obligations that are somewhat less fundamental.

Under the new constitution, the rela-

tionships between the component parts (entities) of the IARU will be changed somewhat. The regional organizations become an integral part of the worldwide body, with increased authority and responsibility. The "Headquarters" function is transferred to the Administrative Council, with a member society serving as International Secretariat to perform administrative functions in support of the Administrative Council. The IARU president and vice president will be nominated by the International Secretariat in consultation with the Administrative Council, subject to ratification by the member societies; the secretary will be designated by the International Secretariat. The officers may be members of any member society.

THE WARIC IN TOKYO

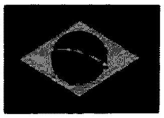
The World Amateur Radio International Conference was held in Tokyo, September 19-21, 1983, cosponsored by the Ministry of Posts and Telecommunications and the Japan Amateur Radio League, Inc., to commemorate World Communications Year. Saif Shahid attended at the invitation of JARL, as their guest. Besides Bangladesh, there were representatives from China, Federal Republic of Germany, Jordan, Korea, Malaysia, New Zealand, Nigeria, Oman, Pakistan, Thailand, Trinidad and Tobago, the UK, and the USA. In total, about 100 people attended the conference. The conference was particularly featured by the attendance of Richard E. Butler, Secretary General of the ITU, who participated in all conference events in addition to his impressive speech at the inaugural function.

The conference was chaired by the late Victor C. Clark W4KFC. The BARL representative was active in all conference activities and working-group meetings. In the concluding plenary session, the chairman read out to the house the news item from the *BARL Bulletin* regarding Wireless Board approval of amateur service in Bangladesh. The house applauded upon hearing the happy news. The conference adopted the Tokyo declaration.

GENERAL SECRETARY IN GERMANY

Nizam Chowdhury, the founder General Secretary of BARL, recently left Dhaka for West Germany for a year-long training in telecommunications. Nizam is one of those fortunate few whose profession and hobby are in the same field. The Annual General Meeting paid rich tribute to the past activities of Nizam in promoting amateur radio in Bangladesh. We wish him success in his career.

Mahbubul Huque Khan took over the office as acting General Secretary for the rest of the term after Nizam's departure.



BRAZIL

Carlos Vienna Carneiro PY1CC
Rua Afonso Pana 49, Apt. 701
20270 Rio de Janeiro, RJ
Brazil

CW operating is much, much more than simply traveling through a new and marvelous international world!

Put all that's happening to the communications world together, and Wayne Green's "Never Say Die" editorial in the January, 1984, issue says it perfectly, and all who really know amateur radio will agree that CW represents the fantastic guardian, the sure link between the first real touch and the final success for radio amateurs.

In Brazil, a continentally-dimensioned country, curiosity for this communication may be the cause for temporary interest, and a no-code Class C was responsible for a new wave of hams, 80 meters and VHF being their immediate goal. Also, CBers have come to amateur radio, trying this new opportunity with its less-populated bands and excited by the news of a no code class.

Little by little, these newcomers discovered CW and what it really meant to be an amateur and to join all the wonderful options they had! At the least, CW is a bridge to working on antenna performances, and so a strong development in this field becomes a new and exciting challenge! And what about electronic keyers? And antenna tuners? And what about DX, the most fascinating "friend-factory" in radio? And what about QRP's fantastic surprises?

Most of all, CW brings you naturally to awards, and so you discover you're operating not just for operating, but because you're looking for something; you have a very stong reason to operate in this or that direction, aiming to hunt awards of all kinds. CW groups in Brazil are doing all they can to provide hams with a tremendous variety of awards.

The PPC Group has close to 20 awards, the CWRJ has almost 10, the CWP is now presenting a very interesting one, the GPCW in Santos has 4, the CWSP has 2—the second possible only if you complete the first—and the ABCW has 2 very interesting awards (one of them aimed at DX operations—the ATWAW). The CWRL, the GCWA, the CWGO, the CWSE, the PACW, the MCG, the MCPR, and all Brazilian groups have at least one award which is CW mode only.

We cannot keep up this rush: Last month's equipment is already obsolete because of competition between manufacturers. And costs are going up and up, and repairs are becoming owners' nightmares! Well, reasonably-priced equipment will pay wonderful dividends in CW, and even homemade QRP will bring you pennies from heaven at almost no cost if junk boxes are explored. Who can afford commercial prices? Only a few, considering this mess all around the world! Only a very strong force can keep amateur radio in many places and in many countries. And this force is the spirit of amateur radio strengthened and reinforced by CW, the most simple, the most efficient, the cheapest, and the most realizable of all options in our hobby.

CWP—CW PETROPOLIS GROUP

Just born in Petropolis ("Peter Land," named after Brazilian emperors Peter I and Peter II), the Petropolis CW group is the youngest of our CW organizations. It is born to stay, according to the bunch of FB radio amateurs chosen to form the operating crew for the CWP Award.

The program is under the command of PY1DFF and PY1QQ (Claudio and Mac, well-known DXmen) with Ossir PY1YOC as right-hand help. Beautiful awards, already printed, and a well-spread net of A1 CW operators are the hope for an immediate success of this new incentive towards the use and the practice of the most simple and efficient of all modes of communications among Brazilian and other radio amateurs: faithful old CW!

The CWP Award may be obtained in three different classes:

Class One—Work 10 Brazilian cities plus two QSOs with CWP members or delegates;

Class Two—Work 20 Brazilian cities plus four QSOs with CWP members or delegates;

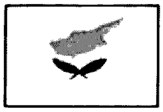
Class Three—Work 30 Brazilian cities plus six QSOs with CWP members or delegates.

Attention—Any CWP members or delegates can be used more than once if worked on different dates or bands!

Same rules apply for SWLs. No QSLs needed, but GCR apply. Fee: 7 IRCs. Mail to: CWP, PO Box 90415, 25600 Petropolis, RJ, Brazil.

CWP members: KA9KUH, PP2ADY, PP7JCO, PT2ACZ, PT2GK, PT7WA, PY1AFA, PY1APS, PY1AYE, PY1AZG, PY1BPR, PY1BVY, PY1CC, PY1DFF, PY1DK, PY1DMX, PY1DRW, PY1DWM, PY1DYO, PY1EBK, PY1EBN, PY1ECL, PY1EWN, PY1JF, PY1KT (YL), PY1MIT, PY1OB, PY1PL, PY1QN, PY1QQ, PY1RD, PY1TBW, PY1TG, PY1UBS, PY1URQ, PY1UTZ, PY1UUW, PY1UWI, PY1VEC, PY1VMV (YL), PY1WXU, PY1YOC, PY1YOV, PY1ZFF, PY2AC, PY2IL, PY2KQ, PY2MC, PY2MT, PY2ORW, PY2RLQ, PY2RRG, PY3MQ, and PY6AMJ.

All OSOs CW mode only; QSLs valid from December 1, 1983, on.



CYPRUS

Aris Kaponides 5B4JE
PO Box 1723
Limassol
Cyprus

THE LARNACA MARINA AMATEUR STATION, 5B4MM

On the south coast of Cyprus there is the town of Larnaca, built on the location of the ancient Greek city of Kition, the city of one of the great Greek philosophers, Zenon of Kition. Larnaca today is a small city of about 60,000 people, with an international airport, a seaport, and a very modern marina for small boats.

The Larnaca marina is under the jurisdiction of the Cyprus Tourist Organization, and it has a radio station for the VHF marine band, with 10-hour daily operation on the channels of international navigation. This station is assisting the overloaded Cyprus Radio and has handled to date over 47 distress calls.

With the increase of foreign craft in the marina and the increasing pressure of foreign boat owners came movement by the management of the marina to set up an amateur-radio station. After many difficulties, 5B4MM finally went on the air in December, 1982. It is the only station of its kind in the eastern Mediterranean.

The station is operating with the personal callsign of the director of the marina, Glafkos A. Kariolou 5B4MM. Installed inside the buildings of the marina, it has an IC-720A, an automatic tuner, and two simple dipoles for 2.182 MHz (marine) and 7.040 MHz. It also has a "Western Yankee" rotary beam for 14, 21, and 28 MHz.

The station is licensed by the Ministry of Communications and Works to operate also outside the amateur band on the international marine frequencies (2.182 MHz, etc.). In this capacity, the station uses the call LARNACA MARINA. Operating daily (except Friday and Sunday), transmission starts at 0830 UTC on 7.040 MHz with a weather bulletin for the sea area between Cyprus, Egypt, and Israel (35B.33B-30A.35A). This area has seacraft coming from the coast of Turkey, usually from America, England, Australia, or New Zealand. There is also a lot of traffic from the island of Rhodes, but more traffic is from Port Said, with boats entering the Mediterranean.

Information given by the station besides the WX report includes exchange rates of various Mediterranean countries, data on navigational beacons, hazards, and radio beacons. Given on request is medical advice, minor engine repair assistance, exchange of messages with other stations, relaying, and any other service within the framework of law and for the security of human life at sea.

The position of every craft (latitude, longitude) as well as the weather conditions facing it is recorded in detail, and routes of all are followed daily. In case there is unexplained absence from contact schedules, the embassy of the country to which the craft belongs is notified and also a general search call is given by the marina station.

At 0900 UTC, 5B4MM interrupts its transmission on 7.040 MHz and moves to 14.313 MHz, taking over from the international maritime amateur net station, INTERMAR (located in Hannover, Federal Republic of Germany, with OM Arno DK9SS). The same work is repeated here for sea areas around Sweden, England, the Canary Islands, and Port Sudan, including the Indian Ocean, depending on conditions. Here, important bulletins are issued about yacht thefts, missing boats, private raids, etc.

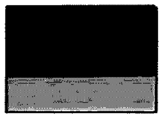
At 1000 UTC, the microphone goes back to Arno and 5B4MM listens periodically between 1000 and 1015 UTC on 21.380 MHz and from 1015 to 1030 UTC on 28.666 MHz.

The frequency of 14.313 MHz is used by six stations worldwide in turns, one being 5B4MM, on a 24-hour basis for maritime mobile radio amateurs. Many amateurs owe their lives to this completely voluntary service.

From the 5B4 point of view, the publicity given to 5B4-land is invaluable, and from the tourist side it is enough to say that yachts following the Cape Town and stateside route change their route to visit and get to know 5B4-land and its people.

The sked of 5B4MM, daily except Friday and Sunday:

7.040 MHz, 0830-0900 UTC
14.313 MHz, 0900-1000 UTC
21.380 MHz, 1000-1015 UTC
28.666 MHz, 1015-1030 UTC



FEDERAL REPUBLIC OF GERMANY

Ralf Beyer DJ3NW
Opferkamp 14

Federal Republic of Germany

INTRUDER WATCH

Almost everyone has experienced radio interference by stations not belonging to the Amateur Radio Service. But most of us ignore their transmissions if heard on our exclusive amateur-radio bands or subbands assigned primarily to ham radio. The average ham simply tunes to another frequency and hopes to have more fun there. However, this is not much of a solution to the problem.

The International Amateur Radio Union's Monitoring Service, with its headquarters in England (Region 1) and regional coordinators W7JIE (Region 2) and ZL1BAD (Region 3), addresses the problem on a worldwide basis. A number of national-intruder-watch services provide the

necessary fundamental work. DL4TA, EA4OK, F6GNP, G5XB, HB9OO, I2AMC, LU6DO, OE6KOG, ON5AZ, PA0VDV, PT2JB, and YB9MS—to name a few—are representatives of the intruder-watch services in their respective countries.

The fundamental task of intruder-watch services is the collection of data about intruders on our ham bands. Our national representative, Ralf D. Kloth DL4TA, assisted by DJ9KR and DK3FQ, issues a monthly summary of intruder observations contributed by a dozen corresponding hams. About 500 observations are reported each month, including date/time, frequency, type of emission, identification/nationality, type of radio service, and further remarks. The summaries are circulated to the IARUMS and among the national intruder-watch services, and they are filed with the German FCC.

This documentation encourages the national FCCs to discuss the intruder problems with other cooperating FCCs who have jurisdiction over the reported intruders. Successful negotiations, for example, moved Radio Cairo from 7050 kHz out of the 40m band, removed a strong second harmonic emission of Radio Free Europe on 14330 kHz, prevented the establishment of a fixed R/T service between Madrid, Spain, and Malabo, Equatorial Guinea, on 21400 kHz, and convinced the Iranian press service, IRNA, not to utilize the 40m band for their RTTY transmissions. The majority of cases, however, still need to be resolved. Satisfactory solutions require patience, good will, and cooperation of the various FCCs involved.

A successful action against an intruder needs support by individual hams. The reason is simple: No interfering station can be considered an intruder if there is no complaint. The respective FCC, in turn, can reference number 115 of the ITU regulations which tolerate the assignment of frequencies to another radio service if no interference with existing services is involved. Therefore, as a general rule, do not tune away from an interfering station. Rather, file a complaint with your national intruder-watch representative and give him as much information as possible on the incident. Monthly reports are timely enough.

But you can do more. For example, occupy the frequency of the intruder and zero-beat his RTTY or CW signals. Chances are high that the intruder will start moving, because many commercial and military stations use equipment with no more power than ours. Of course, this technique is most efficient for simplex transmissions (transmit/receive on the same frequency), but sometimes it works out on duplex (split frequency) transmissions, too.

In cases where you are not allowed to communicate with the intruder directly, test your keyer on his frequency with the following test pattern:

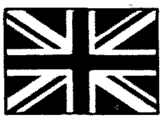
(UI)TA (OE)ASTOTA (OE)ASTX
MEVDUNARODNOJ L(IM)BITELXSKOJ
POLOSY (OE)ASTOT POVALUJSTA OSY
TOT(OE)ASVE

The letters shown in brackets should be keyed with no separation between them. It appears that some people in the eastern hemisphere interpret this pattern as "This frequency is part of the international radio amateur band—please QSY immediately." Some intruders have shown appropriate reaction. Thanks for this hint to ZL1BAD and *Ham Radio*, October, 1980.

In another attempt, DL9AH ran an automatic test in CW on the frequencies of broadcast stations in the 40m "exclusive" amateur-radio band, signing with his callsign. His 1-kW output signals—legal for a plate dissipation of the final amplifier not exceeding 150 Watts—could not be missed by potential broadcast listeners. The net result, however, *is still* to be determined.

Some people were able to confuse the woodpecker and make him move by a string of very-much-shortened dots from an electronic keyer. The "weight" control of the keyer did the trick. The efficiency of this measure is difficult to assess, particularly in the light of the sophisticated pulse coding of the woodpecker uncovered by G3PLX (*Wireless World*, April, 1982). But it is a fact that the woodpecker showed up less often when he had to share the frequency with a "string of dots."

All together, there are many ways to fight intruders, ranging from monthly reports to the intruder watch to the activation of occupied frequencies by whatever method is appropriate. In many cases, the required effort would take up only a few moments of your operating time. Wouldn't it be rewarding to spend this time to help defend our hobby?



GREAT BRITAIN

Jeff Maynard G4EJA
10 Churchfields
Widnes WA8 9RP
Cheshire
England

1983 was a milestone year for the RSGB (Radio Society of Great Britain) with membership passing 35,000 for the first time ever. This increase shows a total growth in membership of 75% since 1977 and, I think, is due to two major factors.

First, there has been a steadily-increasing amateur population in the UK. The introduction a few years ago of the code-free Class B license (G8, G6, and G1 calls) for VHF only (144 MHz and above, to be more accurate) persuaded a great many more interested people to consider seeking a license.

Second, the increasing awareness of technology by "the man in the street" has broadened the spectrum of potential amateurs. There are also two particular technology-related areas that undoubtedly have produced a spin-off interest in amateur radio. These are computing and CB.

The UK has the highest per capita density of personal and home computers in the world. It is becoming increasingly difficult to find someone who does not own some form of computer. Although most computer/amateur-radio interaction has been from hams becoming involved with computers, there is evidence to suggest that computer enthusiasts have been attracted to amateur radio by applications such as satellite tracking and propagation prediction.

A recent survey of members of BARTG (British Amateur Radio Teleprinter Group) included questions about computers used now and planned for the future. Of the respondents, almost 65% currently have some form of computer system available for shack use. The predominant model is quoted as being from Sinclair (Timex in the US), although no breakdown is given between models. BBC and Commodore feature high on the list as well. Although the number of computers planned for the future is still only around two-thirds of respondents, the capabilities desired take a jump. Those hams currently into computing obviously want more use of discs, expanded memory, and printers. Clearly those aspects of amateur radio benefitting from computing (AMTOR, packet radio, satellite tracking, etc.) will be well represented in the UK.

I think I have mentioned previously that CB has been the biggest non-event of the decade as far as the UK is concerned. One-year CB licenses are being allowed to lapse in droves, and new license take-ups are very slow. No need to spell out the reasons for this. However, there has been a spin-off for amateur radio.

Many CBers who originally scorned amateur radio soon realized their mistake when legal CB first took off and 27 MHz was filled with the usual meaningless waffle (to say nothing of QRM, QRN, etc.). Couple this disenchantment with widely-available scanners listening to the (relative) calm of two meters, and you have a recipe for more hams.

Some interesting sidelines on UK CB—the 1984 version of the license specifically prohibits the playing of music and the retransmission of radio and television broadcasts; license holders must be aged 14 or more; loading coils can be located anywhere in the antenna and not only at the base (although antenna-length restrictions remain).

Back to the RSGB. The Society is also moving from strength to strength because of the increasing needs for amateur radio to be effectively and continually represented at government and other high levels in society. Continuing demands on our precious frequency allocations (particularly at UHF by the Ministry of Defence), increasing pressure for further restrictions on operating, regular misunderstanding and misquoting by the media, the difficulties of obtaining planning permission for towers, and the ever-present confusion with CB—all of these demand a strong representative body for amateur radio.

We are fortunate indeed to have such a body in the Society, but there are many other facets to the RSGB. The most obvious, and indeed most welcome, is the monthly *Radio Communication. RadCom*, as the Society's magazine is universally known, is not the only UK magazine devoted to amateur radio, but it is clearly the best and most comprehensive.

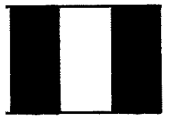
The Society operates an incoming and outgoing QSL bureau for all members. The service is free except for the provision of stamped, addressed envelopes with the incoming bureau. Outgoing cards need only be sorted into alphabetical order and dispatched to the QSL Bureau Manager. Incoming cards are handled by a number of sub managers, depending on one's callsign. Envelopes are dispatched as soon as the postal weight limit is reached—this gives the recipient some flexibility in rate of return.

The Society represents the amateur population (including nonmembers) in relations with the governing Department of Trade and Industry. This not only includes constant lobbying on behalf of amateurs, but also includes the holding (by the Society) of all repeater and news-bulletin station licenses (UK stations are not allowed to establish personal or closed-group repeaters or to broadcast to non-specific recipients).

The Society's full-time staff coordinates a number of volunteer groups handling, among other things—

- planning applications
- intruder watch (regularly reporting on ham-band intruders)
- IARU representation
- Radio Amateur Emergency Network (RAYNET)
- repeater working groups
- propagation studies

Perhaps the best thing about the Society is that all of the above, *including RadCom*, costs only $20.00 per year. Enquiries not to the writer, please, but direct to The Radio Society of Great Britain, Alma House, Cranborne Road, Potters Bar, Herts. EN6 3JW, England.



ITALY

Mario Ambrosi I2MQP
Via Stradella, 13

Italy

Giancarlo Martelli I0XXR
Via Bevignani, 18
00162 Rome
Italy

The most important news from Italy is the new meeting that has been held in Rome with the management of the Telecommunication Department of the Ministry of P & T. With the presence of the Minister (I8XNG), the situation has been carefully examined and there is a much more hopeful possibility of reaching an agreement. A press release issued by the Ministry talks about "the possibility of allowing hams to use 2 meters mobile" and "a more effective presence of radio amateurs on 3.5-3.8 MHz."

Reading between the lines, it does not seem possible to go back exactly to the previous situation, but probably we will be allowed to use 3500-3525 and 3775-3800 plus another 50-kHz slice, and we will be allowed to go out of those frequencies for "replies to international calls." This way nobody will lose face and everybody will be happy.

It seems that the change of approach to the problem is mainly due to the personal interest of I8XNG and to the strong opposition to the new rules by the management of the Italian amateur league (ARI). All the management has resigned from the positions held.

73 CONTESTS

Propagation has not been too good, but a few of the local big guns have participated in the contests on 40 and 80. On the lowest band, they have not paid too much consideration to the new rules and they have operated on the 3775-3800 portion of the band that is at the moment off limits for us.

Scores probably will be on the same level as last year. There are some doubts about the rules that are assigning 5 points to USA contacts and 10 for the rest of the world. It would be better to give 5 points for contacts with your same continent and 10 for DX.

PROPAGATION

Maybe you are interested in knowing what happens here in this period of low sunspot numbers. If you turn on the rig at 0700 local time, the only possibility (during January and February) is to go on 40 and try to work South America or VK. The band opens on 20 at 0730; you can "smell it" from the voices of UB5s and UA3s talking with each other. A few minutes later you start receiving weak signals from the Pacific. If the call is just a bit more exotic than a VK or ZL, the pileups are incredible. This situation lasts up to 0930; the skip then shortens and on 20 you have only Europe.

The choice is now between 10 and 15. Ten is very often completely closed. When not, it's very easy to find UJ8, UL7, AP, A4, and 4X4. On 15, the situation is the same

with a few more possibilities to YB, VK, 9M, VS6, and often Japan.

At lunchtime, the propagation on 10 and 15 opens to Africa. There are few stations operating from there, but when they do, their signals are always vary strong. In the afternoon, 20 meters opens to the US via long path and to the Far East.

The evening offers us the US via short path on 20, South America on the same frequency, and good openings on 40 to the Far East and Africa, followed shortly by 80 meters. The US is workable between 2300 and 0500 on both 40 and 80.

LOCAL HAM PRODUCTS

VHF and UHF antennas of Japanese, American, and French production are very easy to find in local shops. A lot of approval has been given to soma new locally-produced antennas and in particular to a 4-element delta loop with 13 dB of gain, a 12-elemant delta loop for 2 meters with 18 dB of gain, and the same one for the 70-centimeter band. A 23-elament log periodic from 130 to 1300 MHz has just begun to be sold, while a 12-element log periodic for the 13-30-MHz band is ready to be introduced in the market. Will provide you with more information later on.

SOCIAL ACTIVITY

I want to tell you about two examples of radio activity in Italy. First, the new QTH of the radio club of Civitavecchia (in the Rome area) is an old rail-truck that has been moved to the top of a 2000-foot hilt! It is a strange QTH but can be a suggestion for others. In Italy, old railcars are not very expensive!

Second, there is a new emergency communication center for the Milan county authorities. It started activity at the end of 1983. The authorities provided all the logistics while the local radio shops have donated most of the equipment. The emergency center can work on all bands and has its own repeaters on VHF and UHF. It can work RTTY, fascimile, and satellites. Beams are available on HF, while particular attention has been given to the 80-meter band which is the only one capable of complete coverage of all the nation. The center can provide space for 6 operators at the same time. The antennas are mounted on top of a 150-foot building. A truck equipped with HF, VHF, and UHF rigs is always ready for use. The conference room of the center can accommodate 500 people.

DX

The expedition to VU7 Laccadives has been the event of the month. It was very easy for us to work them, and a few of the local DXers have tried to work as many operators as possible as the callsign was the same for all of them. 15 meters was the easiest band, followed by 20. The activity on 10 meters was limited, but VU7 signals have always been strong.

The expedition also was spending a lot of time on 40 and 80 and this has allowed even the small pistols to work them. We are now waiting for Clipperton and Kermadec, and let's hope we will be in a position to say again it was not too difficult to work them.

T77C (ex M1C) is the first San Marino ham to achieve DXCC honor roll, and in the meantime, he has started to be active on 160. You can find him around 1.840 MHz. He has worked some Ws already and is looking for many more.

de I2MOP

Due to the limitations set by the Ministry of Posts and Telecommunications (MPT) to ham activity in Italy, a very heavy ill humor has befallen Italian radio amateurs. At the time this column is being written, we have the following situation.

- The 3.5-MHz band is reduced for amateur use to two thin slices, 3.613 to 3.627 and 3.647 to 3.667 kHz. Looking at these crazy numbers, one can understand that the 3.5-MHz band has practically been withdrawn as far as amateurs are concerned, because no serious DX or CW traffic may be carried on, referring to the IARU band plan.
- The MPT has assigned the band frequencies to other government services, mainly to the Defense and Interior Ministries. Every possible effort has been spent to explain to the MPT officials (and to their so called technicians) that throwing Italian hams out of the band is meaningless, because the whole band is shared by foreign amateurs with foreign fixed and mobile services. They don't seem willing to understand these very simple matters, but the general opinion is that the MPT has already compromised itself with the assignment (or the promise) of wide-frequency subbands into the 3.5-MHz band to government agencies. Moreover, the MPT persists obstinately to sustain the principle that the "sharing" concept for a band means that it must be divided into subbands.
- The very old law ruling amateur activity in Italy states that every amateur station should be installed in the residence of the amateur and that the station may be moved only after the MPT has given written permission. The only allowance ie made for the 144-MHz-and-up rigs with power not exceeding 5 Watts, which can be moved without permission. The law states "moved," but not operated on the way, which means that in Italy mobile operation is forbidden on both VHF and HF.

Although such statements make repeaters illegal also (which are installed on hilltops and not in the licensee's home), for many years Italian amateurs have used 144 mobile, playing with the ambiguity of the 144-MHz free-moving rule. They have installed a very efficient repeater net which played a big role during the emergency operations carried on during the course of the dramatic Friuli, Sicily, and Irpinia quakes.

- The new WARC bands have not yet been assigned to amateurs in Italy, and no provision has been made on the matter. Rumors are that the 10-MHz band will be divided into subbands, following the concept of the so-called engineers of the MPT, who seem to ignore that interpretation of the sharing concept is different all over the rest of the world and that radio waves don't know borders. On this basis, no more than 10 kHz will be allocated to the Amateur Service.
- For the past 25 years, the Administration did not care much when the Italian amateurs bypassed some outdated and ridiculous rules. In fact, they used the entire 3.5-MHz band according to the IARU band plan, they installed repeaters, and they worked 144 mobile. And the Administration did not move a finger in order to issue more adequate rules.

The reasons for the sudden and unexpected prosecution campaign of the MPT against amateurs, which started in June, 1963, are still not clear. Tight monitoring, inspections, fines, and license suspensions left the amateur community astonished—the more so because the Italian ether is the most chaotic and undisciplined in Europe, and amateurs considered themselves a quiet island in this stormy sea. Why harass the official amateurs when lots of illegal transmissions are carried on every part of the spectrum without apparent opposition by the MPT, asked the amateurs.

Unfortunately, in an emergency period like this, ARI showed a late and weak reaction. In the past years, ARI settled on lazy and ineffective political action in order to clear up problems of the amateurs with the MPT. One month ago, a meeting of ARI President Rosario Vollero I8KRV, the ARI Board, and the MPT officers was held, with incongruous results. The officers confirmed their will to allocate to the amateurs on the 3.5-MHz band only 100 kHz, from 3,500 to 3,600. Such an allocation would compel the phone stations to invade the CW portion of the band, with certain reactions from the IARU and foreign amateurs. At the same time, the MPT officers warned that 400 new inspectors would be put in service soon, and they announced tight inspections and checks also on the highways and roads to prosecute mobile operation. The reaction of the amateurs and of the ARI members was very heavy. President Vollero was accused of being the man responsible, having held the presidential charge for about ten years. His attitude toward the MPT was judged incongruous and supine, and he was charged with inadequate representativeness and lack of effective policy. At that point, Vollero and the entire Board of Directors resigned.

Rumors around were of plans of direct fights against the MPT: Somebody suggested an international mass mailing of cards directed to the Republic President, Sandro Pertini, with petitions on Italian amateur rights; another claimed that an occupation of the 3.5-MHz band with thousands of ham stations would be effective.

Some favorable movement started to appear inside the MPT. Maybe some politicals started to fear unfavorable damage to the MPT image, especially as far as foreign administrations and the IARU were concerned. The Minister of Telecommunications, in person, and the General Director of MPT suddenly invited the ARI President and the Board to a new meeting in the Minister's Gava office on January 20. That looked to be a bypass of the officers who had started the battle. In the course of the meeting itself, it appeared that some recognition was made of some requests of the amateurs, but it seemed clear also that the MPT was trying to get some concessions concerning renunciation of a part of the 3.5-MHz band.

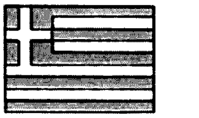
The MPT offered recognition of the VHF and UHF repeater net, a provisional allowance for mobile operation with 5-Watt maximum input, a possible early opening of the 1.8-MHz band and of the WARC bands, with some power and frequency limitations, but remained adamant about giving only 100 kHz to the amateurs on the 3.5-MHz band.

The ARI representatives, with members' pressure at their shoulders, refused to accept the 3.5-MHz proposed solution, stated many reservations about the proposed 5-W power input maximum rating for mobile use (mainly as far as HF was concerned), and said that the proposals would be discussed at the next ARI general meeting. A further meeting with the MPT officials was set for April 3, 1984.

Just after that date, a big international meeting of radio amateurs on emergency subjects will take place in Erice, Sicily, and IARU Region 1 representatives, the Minister of Telecommunications, and the General Manager of MPT have been invited. It appears clear that the MPT does not want to appear on that occasion as an enemy of amateur radio, thus the political pressure on the MPT technical staff which promoted this sort of war.

Surely there will take place a big battle at the next general meeting of ARI (which will be held in Rome next March). President Vollero I8KRV and his staff will try to be reconfirmed as heading the association, showing the partial success of their late effort. They will have the regional committees (which are the statutory organs which represent the members) to convince. The regional committees are of the opinion that a more incisive effort is needed in future approaches to the MPT and this shall be possible if the direction of ARI is given to amateurs who are in the position to be more respected by political and administrative personnel of the Italian government. That means that they should have a very good position as far as ties and friendships in the right direction are concerned. That does not mean that ARI should be politicized; it means only that ARI needs at its head people capable of some degree of political maneuvering. And that, in a country like Italy, where nothing is possible without politics, is essential also to defend amateur rights.

de I0XXR



GREECE

Manos Darkadakis SV1IW
Box 23051
Athens 11210
Greece

With the increased popularity of personal computers among radio amateurs worldwide, some interest appeared among SV amateurs three years ago. But, as in every small country, things were not so easy and some time had to pass by before availability became true for home computers in Greece. I think that today there are more people here selling computers than wanting to buy one!

Nowadays there is access to British and American markets and all big names plus the duplicates from Taiwan and Hong Kong are well represented. I have heard, lately, that the first Greek-made home computer is coming on the market, but up to now the only thing I know is that its name is Hermes (the Greek god and messenger of the gods). I will let you know when I have more information.

Of course, most of us want to go on RTTY with computers, and since the computer/modem combination is cheaper than the ready-made unit, this helped the interest to grow a lot. Now, there is a slight difference in software availability when someone comes to the point of choosing between an American and a British machine. In my opinion, the British ones lack serious programs for the radio amateur; if there are some, very few of them appeared in British ham magazines. On the other hand, American-made machines are more expensive, but there is plenty of software valuable to radio amateurs. Macrotronics, Kantronics, Micro-80, Inc., etc., for sure deserve a "bravo" for their excellent work in the amateur field. In the ham magazines, also, there are plenty of programs for radio amateurs; even computer mags such as *80 Micro*, *Rainbow*, *Run*, etc., include amateur-related material.

Although I have a TRS-80 Model I, level II, which has been out of production for some years now, I am able still to find programs for it today—and a lot of them.

Despite the situation described above, most of my fellow amateurs have British-made machines like Sinclair's ZX-81 and ZX-Spectrum. American-made machines are represented with a few Commodore VIC-20s and 64s, some TI 99/4As, and quite a few of Tandy Models I and II.

By the way, European readers will find a lot of ideas as well as programs in a column named "Rubrique micro-informatique" which appears every month in REF's (French Radio Union) magazine. Both British and American machines are supported. Listings are very well printed and the people there are doing an excellent job.

See you next month.

LIBERIA

Brother Donard Steffes, C.S.C.
EL2AL/WB8HFY
Brothers of the Holy Cross
St. Patrick High School
PO Box 1005
Monrovia
Republic of Liberia

The modern amateur radio is more and more push-button controlled. There are some amateurs who shed tears as they see this happening. The home-brew rig is a rare thing these days and these amateurs are sure that the whole hobby is going to the dogs. At least they see great changes taking place and they see little that is positive in the direction that things are going.

Traditionally, amateurs have been enterprising and innovative and the modern amateur has not lost this quality. A fertile mind and an energetic personality are not dependent on how the designers put together a radio. They cannot be squelched and if they are not building rigs from scratch, they are probably designing circuits to track satellites. One thing is certain: Amateurs are not sitting around doing nothing. As always, they are contributing significantly in the field of communications and communication equipment.

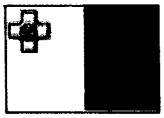
But here in Liberia we see these modern push-button radios from quite a different perspective. We tend, very quickly, to develop an aversion to switches. With our near-hundred-percent humidity, our tropical temperatures, and our harmatan dust, our switches stop switching. The air-conditioned home is not unknown, but not all amateurs have that luxury.

In this country, the amateur becomes the community repair man. "He knows everything about electricity." Into his shop comes anything that has ever seen an electron. When he takes off the cover, he finds molded coils and capacitors, mildewed circuit boards, rotted dial cords, rusted chassis . . . it is very discouraging.

The amateurs here are like amateurs in other parts of the world. They like their equipment and they do not sit around moaning as things deteriorate. They are very ingenious in devising ways to keep out moisture and dust. Some build cabinets with handy sliding doors to house their radio station. A desiccant inside helps to control the moisture. Others build shelves over their desk or table with air spaces under them. One or two well-placed light bulbs provide a convenient low heat source, and if everything is covered with a heavy cloth, it provides effective moisture and dust control.

It seems that in spite of everything that is done, it is necessary to polish the covers and lubricate the nuts and bolts several times a year or they will rust. During the rainy season, *it rains*. In Monrovia, it will total more than two hundred inches a year. During the dry season, there is the harmatan. The desert dust rises to more than forty thousand feet and blows across the whole country of Liberia. The natives like the harmatan because it tempers the blazing heat of the sun, but housewives and amateur-radio people do not like it at all.

In the tropical climate, everything that switches is going to stop switching much too soon. An obvious solution is to gold-plate all switch surfaces. Obvious also is the fact that so doing solves one problem while creating another!



MALTA

C. A. Fenech 9H1AQ
35 Main Street
Attard
Malta

Since writing my first column in this widely-read magazine (June, 1983), I have the following to add. Quite recently, Maltese radio amateurs were given permission to own hand-held, portable, and mobile equipment. The use of this type of equipment is restricted in that it has to be used forming part of the fixed station at the owner's address. Permission to use hand-held and mobile equipment from any other location has to be sought by the club from the W/T Office and this permission may be granted only on special occasions such as Field Day. The use of mobile equipment while in motion is strictly forbidden. This bit of information may be of interest to those who would like to come and spend some time on the island, because they will be able to bring along with them small VHF rigs which are not as heavy as the HF rigs. The VHF rigs must, of course, comply with the local regulations and must not cover frequencies higher than 146 MHz.

DXPEDITION

Some thirty members of the Malta Amateur Radio League (MARL) decided to put Comino Island for the first time ever on the air. This very small island lies about 15 minutes by boat from the mainland. The callsign used was 9H1MRL/A. Comino Island has only a handful of inhabitants. There are two very small but beautiful bays, the Blue Lagoon and Santa Maria Bay. The very luxurious Comino Hotel is also found on this little island, and it is usually visited by those who are interested in windsurfing.

The amateurs who took part in this expedition left the club premises in Attard (a small village situated in the center of Malta) at about 0400 GMT. That Saturday saw them taking all kinds of foodstuffs to last them a whole weekend. They also took with them an HF FT-101 transceiver and a TS-7000 VHF rig belonging to 9H1ES and 9H1FX respectively. The group arrived at Cirkewwa at about 0600, where all gear was loaded onto the patrol boat which took them to the islet. After all gear was taken from the boat, each one had to take his share of the load where it was decided to set up the station.

It was 0630 when some members started to erect the antennas, which consisted of three half-wave dipoles for 10, 15, and 20 meters for HF and a 12-element yagi for VHF. As there were no trees, erecting the aerials took quite some time, and it was only after a lot of improvisation that they were erected. At about 0745, 9H1O, who started operating the station, established the first contact with Australia, with VK2AKP. It was very astonishing that Sam VK2AKP was a Maltese national who had emigrated to Australia some twenty years ago! A lot of European and extra-European stations were worked both on SSB and CW while many Sicilian stations were contacted on VHF.

AWARDS

The MARL issues three very nice awards: the DIP MED Award, the 9H Award, and the MARL Golden Jubilee Award. The DIP MED Award is awarded to any licensed amateur-radio operator, SWL, or club station on confirmation of 2-way QSOs on the HF or VHF bands. The HF applicant has to work a minimum of 15 of the 26 Mediterranean countries listed. The VHF applicant has to work a minimum of 5 of the 26 Mediterranean countries listed. In both the above, 9H is obligatory.

Albania, Algeria, Balearic Is., Ceuta, Melilla, Corsica, Crete, Cyprus, Dodecanese Is., Egypt, France, Gibraltar, Greece, Israel, Italy, Lebanon, Libya, Malta, Monaco, Sardinia, Sicily, Spain, Syria, Tunisia, Turkey, and Yugoslavia are the countries.

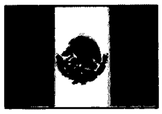
The 9H diploma is awarded to any licensed amateur-radio operator, SWL, or club station on confirmation of 2-way QSOs with 9H stations. Applicants in Europe need 10 points, and applicants outside Europe need 5 points. Each QSO with a 9H1 station counts as 1 point, each QSO with a 9H4 station counts as 2 points, and a QSO with 9H1MRL (club station) counts as 2 points.

No QSL cards are required for these diplomas. Send a certified list signed by another two amateurs together with 12 IRCs or US$2.00 if application is from Europe or 15 IRCs or US$3.00 if application is from outside Europe.

To commemorate the 50th anniversary of the founding of MARL, the League decided to issue a special award to be known as the MARL Golden Jubilee Award. Period: From 1st September 1983 until 30th September 1984. This award is available to licensed amateurs and SWLs (on heard basis).

To apply for this award, one must work 9H5ODC, the special station, which can be worked only once, and any other four 9H stations on any band and in any mode. Each station can be worked more than once on the same band but this must not be on the same day. No QSL cards are required, only a copy of the log certified by the awards manager of the national society or by two licensed radio amateurs. The fee for this award is US$3.00 or 15 IRCs.

Applications for any of the above awards should be addressed to: The President, MARL, PO Box 575, Valletta, Malta.



MEXICO

Mark K. Toutjian XE1MKT
Apartado Postal 42-048
06470 Mexico, D.F.

I guess now and then it would be good to comment on some of the most frequently asked questions in letters that I have received from around the world since I have been a correspondent for *73*. I believe that if a fellow ham or anyone takes his or her valuable time to write, they should receive an answer, and since the answers to their questions may be of interest to many others, what better way to answer than through "73 International"!

In the February, 1984, issue, I commented extensively on the matter of getting a permit from the Mexican government to operate within the country on vacation or when passing through. I would like to add that your mobile or portable equipment should be registered by the customs officials at the border or place of arrival within the country, showing by means of approved documents that you are authorized to have and use such. Proper remarks will possibly be made on your tourist card so you will not have future problems during your vacation.

For our Mexican readers and for those in Mexico on vacation or passing through, *73* magazine can be purchased at practically any international airport in the country. In Mexico City, the famous Sanbourns restaurants, VIPS restaurants, and some American bookstores carry *73*. However, in spite of the relatively recent devaluation of the Mexican peso, the cost of *73* in Mexico (seemingly high locally) is obviously not high. It sells out at once.

Whenever I look for a certain issue when it supposedly is to come out, it's usually already sold out! I remember driving once from one end to the other of Mexico City only to come home empty-handed! (If you have ever been to Mexico City, you will sympathize with me.) So, Mexico sends its congratulations to *73* for a very fine magazine that sells just as well as the "quick tacos" on the streets! Wayne Green certainly does a fine job.

Some have asked me how I got started in ham radio. Well, besides the help I personally received from the Juarez City Radio Club and the Coatzacoalcos, Veracruz Radio Club (and especially from Mario Krespo XE1MCK), I read an article called "'Ham' Radio . . . A Hobby That Can Help Others," in the *Awake!* magazine (April 22, 1976, issue). I especially enjoyed it for its exactness and because, to me, it was written in plain language for a real beginner like myself. Back in those days, *Awake!* printed 9,925,000 copies of each issue in 32 languages! So it had to be simple and to the point and at the same time very interesting.

It also had a wide circulation in Spanish, here in Mexico. If you don't believe me, let me send you a photocopy of it in Spanish or English. Just send me a postal coupon and a few pesos and I'll have it Xeroxed and sent to you right away! Would be nice to have more literature for beginners (easy to understand) in Spanish as well! You never know, Wayne Green may surprise us some day! That would be wonderful for our Latin American colleagues! Think about it, Wayne! How many other thousands of future hams might get their start in the ham world by means of a beginner's book in Spanish, especially if it were very simple and up-to-date!

Most of the Spanish literature that I have seen available is old or just too technical for the beginner. (One possible reason for having so few hams in Mexico as compared to the US?) A beginner's book in Spanish could also aid the English-speaking to learn ham terms in Spanish. Then go for your Mexico license before coming down to warm Acapulco on vacation! It's just a six-hour drive from Mexico City, and you can stop off in Cuernavaca (known as the "eternal spring" since it is warm all year round) and then in Taxco to buy some good silver at low prices! If you would like to go out of your way, go to the state of Guanajuato, just north of Mexico City by a few hours, and have a leather case handmade for your handy portable!

Yes, Mexico is a very interesting and unique country with much variety and different cultures throughout. Spanish is the

Yagi Fear?

Forget it. Whether for construction or comparison, this Atari program zaps every design problem.

Amateur-radio operators and shortwave listeners are always in need of a better antenna or an easier way of designing one. Also, teachers need a way of comparing one design with another as examples for their students.

Many superb antenna construction articles have been written over the years. However, there is still a frequent need for a design based upon a new frequency or number of elements. With the aid of the computer it is easy to compare design parameters for antennas having a differing number of elements.

This program was developed on an Atari computer for a yagi antenna having from 2 to 6 elements and is based upon the parameters of an idealized antenna model. The formulas used in the program have been generalized to increase simplicity. As a result, antennas constructed from the program data will function as indicated by the parameters. However, small ajustments of element lengths and spacing may prove beneficial for some parameters and applications—particularly if the same formulas are used for an increase in element number beyond six. An element spacing of 0.2 wavelengths was selected to reduce the effect of critical tuning parameters.

To simplify the construction of the program, repeating text messages—relating to element name, etc.—are stored as string statements. Several advantages occur as a result. It is easier to handle a string as a print requirement than it is to repeat the typing of each print statement. Of course, a real advantage occurs during editing of the entered program when a change or correction is to be made in the print statement. By having the statement contained within a string, a one-time "fix" in a single statement represents the change for every time the statement is called to print. In addition, a separate group of print statements was developed for each set of elements and for frequencies above and below 70 MHz. The frequency split was selected to accommodate the change in dimensions from feet for frequencies below 70 MHz to inches for frequencies above 70 MHz.

Dimensions

Dimensions for the antenna elements, element diameter, and element spacing are established as a function of wavelength by dividing 300 by the selected frequency in megahertz. Adjustments to the wavelength are made to compensate for a generalized velocity factor.

The program assumes that dimensions remain the same for an antenna array of 2 to 6 elements. With an element spacing of 0.2 wavelengths, dimension tolerances tend to be less critical than those arrays designed with narrower spacing. Element dimensions are given as a decimal for program convenience. However, generalized fractional dimen-

I—For/next loop counter

sions are also provided, based upon assumed available standard tubing dimensions.

Caution is suggested when selecting a boom diameter for an antenna designed for a frequency below 10 MHz. Although the program indicates a minimum boom diameter to provide support for the array, load factors, unsupported boom lengths, etc., must be considered. As the operating frequency decreases, the computer-derived boom diameter tends to be too small. The program does not restrict the design of a low-frequency yagi even though it may be mechanically impractical to build. There are times when the dimensions are desired as a comparison with other antenna types. A cautionary note is provided in the design printout, indicating that an alternate antenna design should be considered.

Feedpoint

The question most asked about an antenna design is "How is the antenna to be fed?" For user convenience, coaxial cable is the most desired. However, not all antenna designs will provide an unbalanced feedpoint for coax. Therefore, if the antenna has a balanced feedpoint, a matching device will be required to convert from a balanced feedpoint to an unbalanced transmission line. A balun or gamma matching device will satisfy most applications.

Feeding a balanced feedpoint directly with coax causes a feedpoint discontinuity which will be observed as a vswr problem of about 1.5:1 which cannot be corrected by typical antenna adjustments. If only the balanced/unbalanced discontinuity problem exists, little user notice will be observed if the transmitter will tolerate the vswr incurred. Corrective action must be taken for a vswr exceeding 2.0:1 because a problem exists somewhere in the antenna feedline system. Many commercially-built transmitters have a vswr detector in the rf output circuit to limit the power output when the vswr exceeds a selected value. That vswr value may vary from 1.4:1 to 1.7:1, depending upon the manufacturer.

The radiator element of a yagi antenna is balanced whether or not it is broken (cut in the center). When broken, a single element in free space would exhibit a center feedpoint impedance of 60-70 Ohms balanced. As additional parasitic elements enclose the radiator to form a yagi, the feedpoint impedance may decrease to a value as low as 10–15 Ohms. The feedpoint will remain balanced regardless of the number of elements surrounding it. The specific feedpoint impedance will be determined by element spacing and radiator element length-to-diameter ratio.

Most baluns have a 4:1 impedance ratio with the highest impedance appearing at the balanced terminals and the lowest impedance at the unbalanced terminals. When used with a yagi, the balun could be attached to a "T" match on the unbroken radiator at the 100-Ohm balanced point. It would then match coax at 50 Ohms. A more practical

```
                    CUSTOM DESIGNING A YAGI ANTENNA

THIS ANTENNA WAS DEVELOPED ON AN ATARI COMPUTER
AS COMPILED BY HUGH WELLS  W6WTU --JULY 1981.

THE ANTENNA'S CENTER FREQUENCY IS 146 MHZ.
THE YAGI IS TO HAVE 5 ELEMENTS.

* THE FOLLOWING DIMENSIONS APPLY TO THE DIAGRAM AT THE BOTTOM OF THE PAGE.

THE REFLECTOR ELEMENT IS 38.99 INCHES LONG.
THE DRIVEN ELEMENT IS 37.04 INCHES LONG.
THE FIRST DIRECTOR ELEMENT IS 35.19 INCHES LONG.
THE SECOND DIRECTOR ELEMENT IS 33.42 INCHES LONG.
THE THIRD DIRECTOR ELEMENT IS 31.76 INCHES LONG.

THE FORWARD GAIN OVER A DIPOLE IS APPROX. 9 DB
OVER THE FREQUENCY RANGE FROM 141.62 TO 150.38 MHZ.

FORWARD BEAM WIDTH IS APPROX. 40  DEGREES AT THE 3 DB POINTS.

FRONT-TO-BACK RATIO IS APPROX. 19 DB.

WHEN BUILDING AN ANTENNA, CONSIDER THE WIND AND BIRD LOADING
WHILE SELECTING THE ELEMENT DIAMETER AND MATERIAL.

THIS YAGI DESIGN ASSUMES A CYLINDRICAL ELEMENT OF CONSTANT DIAMETER.

THE OPTIMUM ELEMENT DIAMETER IS 0.234 INCHES.
SUGGEST USING 1/4 INCH MATERIAL.

THE OPTIMUM ELEMENT SPACING FOR HIGHEST FORWARD GAIN
IS 0.200 WAVELENGTH.

THE SPACING BETWEEN ELEMENT CENTERS IS 16.17 INCHES.

SELECT A MINIMUM BOOM DIAMETER APPROX. 1 1/2 TIMES THE ELEMENT DIAMETER.
WITH THE APPROX. DIAMETER BEING 0.5 INCHES.

IF THE ELEMENTS ARE ACCURATELY CENTERED ON THE BOOM, INDUCED CURRENT WILL
BE MINIMUM ALLOWING THE BOOM TO BE METAL IF DESIRED. INSULATION BETWEEN
THE BOOM AND THE ELEMENTS IS NOT REQUIRED.

THE FEED POINT IMPEDANCE OF A CENTER BROKEN DRIVEN ELEMENT IS LOWERED
TO APPROX. 10-20 OHMS (BALANCED) WHEN THE ELEMENT IS ENCLOSED
WITHIN PARASITIC ELEMENTS.

BECAUSE OF THE LOW IMPEDANCE VALUE, A MATCHING DEVICE SUCH AS
A 'T', GAMMA, OR BALUN MAY BE REQUIRED.

AN UNBROKEN ELEMENT MAY BE DRIVEN WITH A 'T' OR GAMMA MATCHING DEVICE.

THE FEED POINT IMPEDANCE OF A BROKEN ELEMENT MAY BE RAISED BY INCREASING
THE LENGTH-TO-DIAMETER RATIO. MAKING THE DRIVEN ELEMENT DIAMETER SMALLER
WILL INCREASE THE RATIO.

A FOLDED DRIVEN ELEMENT ENCLOSED WITHIN PARASITICS WILL EXHIBIT
A FEED POINT IMPEDANCE APPROACHING 52 OHMS-BALANCED.

YAGI ANTENNAS ARE FAIRLY HI-Q AND OPERATE OVER A NARROW FREQUENCY
BAND AT AN EFFICIENCY OF 75-95 PERCENT.

THE ANTENNA MUST BE MOUNTED A MINIMUM OF TWO
WAVELENGTHS ( 13.4 FEET ) FROM GROUND AND OR BUILDINGS.

                               BOOM |
          REFLECTOR ----------------|----------------
                                    |
          DRIV ELEM   --------------|--------------
                                    |
          1ST DIR       ------------|------------
                                    |
          2ND DIR         ----------|----------
                                    |
          3RD DIR           --------|--------

                         FORWARD DIRECTION
                                    |
                                    V
```

Sample run.

approach is to use a gamma match (one half of a "T" match) on the unbroken radiator. The gamma match is a variable impedance transformer capable of providing an unbalanced feedpoint having an impedance from about 15 to 100 Ohms which is suitable for most coax types.

Antenna Gain

If an antenna were considered to be a point source in free space where it could emit energy equally in every conceivable direction, it would then have a gain of one. In a practical sense here on Earth, a point source cannot be achieved. A radiating device on Earth requires a support and will also radiate energy favoring one direction more than another. Although a point-source radiator is essentially impossible to construct, it is an ideal mathematical model for establishing gain concepts for practical antennas.

A dipole is a practical antenna which has a predictable and repeatable antenna-radiation pattern which can be described in terms of gain. A dipole, being resonant, will radiate energy perpendicular to the element plane causing very little if any energy to be radiated off the ends parallel to the axis of the element. More energy is radiated in one direction than in another, creating, in effect, a form of energy focusing.

To further understand the concept of gain, consider the antenna to be a transformer with a magnetic field being generated around the radiating element. Energy will be coupled from one element to another if the second element lies within the magnetic field generated by the first element. Of course, the elements must be in the same magnetic plane, as can be demonstrated with the primary and secondary windings of a transformer.

A higher antenna gain is exhibited when more of the radiated energy is coupled from the first element to the second by focusing (concentrating) the radiated energy. It is assumed that the radiated-power value remains constant and only the radiation pattern is manipulated. Since there is only a given amount of magnetic field generated around the first element, it is necessary to concentrate the magnetic field into the area (or direction) of the second element. The process is similar to focusing light energy with a reflector. A concentration of the field into one area has the same effect on the second element as if the radiated power had been increased. Antenna gain has been achieved by focusing the radiated energy.

A yagi antenna achieves gain by placing parasitic elements around the radiator. Each parasitic element is nearly resonant at the desired operating frequency of

the radiator and will absorb some of the radiated energy. By being nearly resonant, each parasitic element creates a phase shift in the energy it re-radiates. Energy radiated rearward creates an out-of-phase condition, reducing the actual rearward radiated energy. In the forward direction, however, the phasing is such that energy radiated by each element is in phase and is reinforced as the energy moves forward. The reinforcement process creates the effect of gain through forward-power concentration.

In creating antenna gain by power concentration in the forward direction, the radiated energy in other directions (areas) around the antenna is reduced considerably. If a measurement is made of the energy radiated in the forward direction and the energy radiated rearward, an antenna's front-to-back ratio would be determined. The front-to-back ratio of an antenna is further indicative of its gain and ability to focus energy.

Beamwidth

Beamwidth is another measurement of an antenna's ability to focus energy. The measurement is made by first establishing the antenna pattern which depicts the relative amount of energy radiated in a single plane around the antenna. The highest concentration of energy in one given direction is the forward direction. Beamwidth is determined by shifting angularly to either side of the forward position where the radiated power is down to one-half (−3 dB) of the forward-power position. The included angle between these two half-power points represents the beamwidth.

As the gain of an antenna increases, the beamwidth will decrease, indicating a higher concentration of energy in the forward direction. During antenna adjustments, a false sense of security can be developed if only beamwidth is observed as a gain factor. Yagi antennas have been known to decrease their beamwidth during adjustment while dispersing an increased amount of energy into a parasitic lobe (a power output in a direction other than the desired forward direction). When taken together, forward gain, beamwidth, and

front-to-back ratio represent the performance parameters of an antenna.

General

Because of the rather lengthy printout for each antenna design, it is recommended that a printer be used rather than attempting to read the data from the screen. However, if a printer is not available, the LPRINT command may be changed to PRINT. To stop the screen from scrolling long enough to read the data, an INPUT command may be inserted into the program. It is suggested that INPUT P$ be inserted about every 20 screen printout lines. Pressing RETURN (ENTER) will allow the program to run up to the next INPUT.

A typical five-element design for 146 MHz is provided to show how the printout should look when the program is running properly.

To run the program, it is necessary to enter only the center operating frequency and the desired number of elements (2-6). As an example of what happens, if two elements are selected, the program will assume the elements to be the radiator and the reflector. Additional elements will be added as directors numbered one through four with number one being closest to the radiator; number four will be the farthest away from the radiator. An antenna diagram is printed at the end of the design printout to provide clarity of construction.

All elements are mounted in a single plane along a boom, with each element centered on the boom (or through the boom) to keep the induced boom currents to a minimum. Material for the boom may be wood, metal, or fiberglass, with only strength and weight being the criteria. Aluminum tubing has proven to be a successful material for both the boom and elements.■

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½"x 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I am looking for an RS-111 in any condition. Any leads will be appreciated.

James A. Ross
7906 Hope Valley Ct.
Adamstown MD 21710

I am looking for the service and instruction manual for the Lafayette PF-200A. I will pay copying and postage costs.

APO NY 09080

I have a large collection of your magazines (dating back approximately 14 years) which I am no longer able to keep in my home.

If you know of any school, organization, or person who might be interested in having these, please let me know. Many of them are in binders and I hate to throw out such a valuable collection.

Can anyone supply information about a type CHC-46140 radio receiver made by Hammarlund? I have a schematic but no chart of values of components. Did this ever have a BC number or other nomenclature?

Harry Church W0KXP/9
PO Box 126
Lebanon IL 62254-0126

I have been teaching at God's Bible School now for eight years. Our school was started in 1900 to train future pastors and missionaries.

This year we started an amateur class in our college department for those who wish to work towards their licenses. We started out with twenty-four, but not all stuck it out. We now have nine with their Novice licenses. All are working toward their Generals, hopefully before the end of this school year. Others are working to finish up their Novice testing and also for further advancement.

What we are asking is, how can we get equipment to help train our students? We don't have funds to work with since this is a faith institution. We have heard that your Ham Help column has been very helpful to others, with ideas and sources for them to be able to obtain supplies and equipment. We would greatly appreciate any suggestions you may have. We are able to give receipts for tax deduction purposes and would be glad to do so.

If you are interested in knowing more about our amateur-class program, we would gladly furnish pictures or other information. We would even be happy to have you come see it for yourself.

Thank you for your time, and may the Lord bless you.

APO NY 09175

I am looking for a transceiver that would operate on all the popular amateur bands. I would like it to have sideband capability and perhaps digital readout. I would like to use this as a base station. Could you tell me where I might find a good up-to-date schematic and parts list?

I also would be interested in a good receiving-system schematic and parts list if such transceiver info is not available. I've looked all over and the best I could come up with is a 13-year-old receiver diagram.

Mike Higgins
1155 Birchwood Manor
Aurora MO 65605

I am an Advanced-class ham with a license that is only about 3 years old. I got into hamming because of my interest as a potential maritime-mobile when we retire aboard our boat.

Working the 14,313 net and other voice nets convinces me that it might be worthwhile to get into CW and RTTY for more reliable, if slower, communications under adverse conditions. I see all kinds of ads for communications interfaces, code readers, etc., and, frankly, I am overwhelmed by the variety of choices. What I should like to see is a good survey article which deals with the various possibilities that are available, making clear the range from the least expensive to the most luxurious, and what the extra bucks will buy one in terms of performance or modes of operation.

I am also interested in the possibility that with an interface between the receiver and a computer one could receive, store, and display facsimile transmissions such as those sent by NOAA. I realize that there is specialized equipment available for the purpose, but it is pretty expensive, and if one could make a computer serve two purposes with the aid of suitable software, that might be a popular route for people in my situation.

Finally, does anyone know how many of us are aready using the various modes of computer-aided communication? Some kind of statistics are needed to help a newcomer like myself avoid, on the one hand, going overboard with expenditures for equipment that will do everything (if there's hardly anyone using the fancier stuff) or, on the other hand, getting the minimum and finding that it won't talk with most of the crowd we want to talk to.

I enjoy *73*—hope someone can help me.

(712)-779-3435

I hope that you can possibly help me via the "Ham Help/Info Requested" column of your magazine.

I am in possession of a 6-channel HF-SSB marine transceiver made by Maritek, model no. SB6-60, approximate date of manufacture, 1973.

I have been able to trace the company through the US embassy here in London (Maritek, 1819 South Central, Kent WA 98031), but letters have been returned "Not Known" and a phone number given was found to be disconnected.

I have at present no information at all on the Maritek SB6-60 and would like very much to have (a) a copy of the workshop service handbook and/or circuit details, (b) a copy of the operations handbook, and any other info (especially that on the settings of the taps of the output stage).

I can arrange to have these photocopied in the US, Canada, or here in the UK, and the original returned. I am willing to reimburse any expenses incurred.

Kris Partridge G8AUU

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

CHICAGO IL
MAY 2

The Chicago Amateur Radio Club's Evening Mini-Hamfest will be held on Wednesday, May 2, 1984, from 6:00 pm to 10:00 pm, at the Edgebrook Golf Course Field House, 6100 N. Central (between Elston and Devon), Chicago IL. Admission is $1.00 and card-table spaces are $3.00. Refreshments will be available. Talk-in on 146.52 MHz. For tickets, space reservations, or more information, send an SASE to CARC, 5631 W. Irving Park Road, Chicago IL 60634, or phone (312)-545-3622.

ST. DAVID AZ
MAY 4-6

The Cochise Amateur Radio Association, Inc., will hold a hamfest (upgraded from a swapmeet) on May 4-6, 1984, in St. David AZ. There will be a flea market and all tailgaters are welcome. Tours planned to Tombstone, the Bisbee Lavender Pit, and other places of interest. Talk-in on .16/.76 and .52 simplex. For more details, contact CARA, Attention: Bob Clay KB7HB, PO Box 1855, Sierra Vista AZ 85636.

NASHUA NH
MAY 4-6

The 10th annual Eastern VHF/UHF Conference will be held on May 4-6, 1984, at the Sheraton Tara, Exit 1, US 3, Nashua NH. Registration is $14.50 in advance and $20.00 at the door. Reservations for the Saturday-night banquet are $15.00 each, payable in advance. For advance registrations and banquet reservations, send a check to Rick Commo K1LOG, 3 Pryor Road, Natick MA 01760, before April 29th. Features will include a Friday-night hospitality room, technical talks by well-known VHFers, rap sessions for the various VHF/UHF bands, noise-figure and antenna measurements, and other activities. Room reservations should be made directly with the hotel (mention the Eastern VHF/UHF Conference) or other motels in the area. For further information, write Lewis D. Collins W1GXT, 10 Marshall Terrace, Wayland MA 01778, or phone (617)-358-2854 before 10:00 pm.

LUFKIN TX
MAY 4-6

The Region Four United States Air Force MARS will hold its annual conference on May 4-8, 1984, at the Rhodeway Inn, Lufkin TX. On Friday night there will be an administrative meeting for the headquarters personnel, state MARS directors, and all of the Region Four officials. For those not attending the meeting, the hospitality room will be open. On Saturday, there will be a series of presentations throughout the day, and that evening a banquet will be held for all delegates and their wives, followed by the annual awards. For further details, contact Ed Langston N5CIP, Conference Chairman, 1123 Sayers Street, Lufkin TX 75901.

SACRAMENTO CA
MAY 5

The North Hills Radio Club, Inc., will sponsor the 12th annual Sacramento Valley Amateur Radio Hamswap on Saturday, May 5, 1984, from 9:00 am to 3:00 pm, at the Placer County Fairgrounds, Roseville CA. Admission is free. Tables and tailgate reservations are $6.00 in advance and $8.00 on the day of the event. Talk-in on 144.59/145.19 MHz. For more information, contact D. Long, 8810 Swallow Way, Fair Oaks CA 95628.

CEDARBURG WI
MAY 5

The Ozaukee Radio Club will sponsor its 6th annual swapfest on Saturday, May 5, 1984, from 8:00 am to 1:00 pm, at the Circle B Recreation Center, Highway 60, Cedarburg WI (located 20 miles north of Milwaukee). Admission is $2.00 in advance and $3.00 at the door. Six-foot tables are $2.00 and eight-foot tables are $3.00. Food and refreshments will be available. Sellers will be admitted at 7:00 am for table setups. For tickets, tables, maps, or more information, send a business-size SASE to 1984 Ozaukee Radio Club Swapfest, PO Box 13, Port Washington WI 53074.

OWEGO NY
MAY 5

The 25th annual Southern Tier Amateur Radio Clubs Hamfest will be held on Saturday, May 5, 1984, at the Treadway Inn, Owego NY (take NY Route 17 to exit 65). The flea market will open at 8:00 am; other activities will include vendor displays and sales, tech and non-tech talks, and refreshments. Tickets for the dinner at 6:30 pm will be available by advance reservation only. Talk-in on .22/.82, .16/.76, and 146.52 simplex. For further information, please send an SASE to Craig P. England KF2X, RD #1, Box 144, Vestal NY 13850.

MEADVILLE PA
MAY 5

The tenth annual Northwestern Pennsylvania Hamfest will be held on May 5, 1984, beginning at 8:00 am, at the Crawford County Fairgrounds, Meadville PA. Admission is $3.00 and children under 12 will be admitted free. A 10-foot inside display table is $5.00 and an outside car space is $2.00. Refreshments will be available and commercial displays are welcome. Talk-in on 145.13, 147.21, 147.03. For more details, write CARS, Attention: Hamfest Committee, PO Box 653, Meadville PA 16335.

GREENVILLE SC
MAY 5-6

The Blue Ridge Amateur Radio Society will sponsor the Greenville SC Hamfest on Saturday and Sunday, May 5-6, 1984, at the American Legion Fairgrounds, White Horse Road, ½ mile north of I-85, Greenville SC. Admission is $3.00 in advance and $4.00 at the door. Food, plenty of nearby parking, and overnight camping with a limited number of hookups will be available. There will be drive-in unloading and loading before and after the hamfest. The area will be available for setups on Friday evening and security will be provided both Friday and Saturday nights. Talk-in on 146.01/.61. For advance tickets, write Mrs. Sue Chism N4ENX, Rte. 6, 203 Lanewood Drive, Greenville SC 29607. For further information, write Phil Mullins WD4KTG, Hamfest Chairman, PO Box 99, Simpsonville SC 29681.

COLUMBIA MO
MAY 5-6

The Central Missouri Radio Association will hold Columbia Hamfest '84 on May 5-6, 1984, at the Hilton Inn, I-70 and Stadium Boulevard, Columbia MO. Features will include forums, a hospitality room, a Saturday-night banquet, a hard-surfaced flea market, display tables, and shuttle-bus service to parking areas and shopping centers. Talk-in on .16/.76 or 220.42/.02. For banquet tickets, reservations for hotels, flea-market spaces or dealer tables, and more information, contact Ben Smith KØPCK, Route 1, Prairie Home MO 65068, or phone (816)-427-5319.

KANKAKEE IL
MAY 6

The annual Kankakee Hamfest will be held on May 6, 1984, beginning at 8:00 am, at the Kankakee County Fairgrounds. Tickets are $2.50 in advance and $3.00 at the gate. Features will include an FCC booth, a large flea market with both indoor and outdoor facilities, shuttle service from adjacent Greater Kankakee Airport, and refreshments. Talk-in on 146.34/.94. For motel reservations, call (815)-939-4551. For further information, phone Don Kerouac K9NR before 5:00 pm at (815)-937-2750, or write KARS Hamfest, 1377 Circle Drive NW, Kankakee IL 60901.

LONG ISLAND
MAY 6

The Suffolk County Radio Club Indoor and Outdoor Flea Market will be held on Sunday, May 6, 1984, from 8:00 am to 3:00 pm, at Republic Lodge No. 1987, 585 Broadhollow Road (Route 110), Melville NY. General admission is $2.00; children under 12 and wives will be admitted free. Indoor sellers' tables are $7.00 and outdoor space is $5.00 (includes one admission). There will be refreshments on the premises and plenty of free parking. Talk-in on 144.61/145.21 and 146.52. For additional information, contact Richard Tygar AC2P at (516)-643-5956 (evenings).

SULLIVAN IL
MAY 6

The Moultrie Amateur Radio Klub will hold its annual Sullivan IL MARK Hamfest on May 6, 1984, at the 4-H Fairgrounds, 3 miles east and 1 mile north of Sullivan on the Cadwell Road. Features include covered facilities, lunch, and a free swapper's row. Talk-in on 146.655/.055 and 146.520. For more information, contact William Guennewig WA9WOB at (217)-268-3139 (evenings).

SANDWICH IL
MAY 6

The Kishwaukee Radio Club of DeKalb IL will hold its annual hamfest on Sunday, May 6, 1984, at the Sandwich Fairgrounds, Sandwich. Tickets are $2.50 in advance and $3.00 at the door; tables are $5.00 each. Overnight camping without hookups will be available. For more information, contact Howard Newquist WA9TXW, PO Box 349, Sycamore IL 60178.

PARAMUS NJ
MAY 6

The Bergen ARA will hold a Ham Swap 'n' Sell on May 6, 1984, from 8:00 am to 4:00 pm, at Bergen Community College, 400 Paramus Road, Paramus NJ. There will be tailgating only and admission for sellers is $4.00 (bring your own table). Buyers will be admitted free. Talk-in on .79/.19 and .52. For more information, contact Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855.

CENTRALIA IL
MAY 6

The Centralia Wireless Association, Inc., will hold its annual hamfest on Sun-

day, May 6, 1984, at the Kaskaskia College Gymnasium, 3 miles northwest of Centralia IL. Admission to the hamfest is free and there will be no charge for the flea-market and exhibit space (a limited number of tables will be issued on a first-come, first-serve basis). Doors will open at 7:00 am for flea-market and exhibit set-ups. Food and refreshments will be available, as well as plenty of free parking. Talk-in on 147.27/.87 and 146.52. For further information, contact Bud King WB9QEG at (618)-532-6606 or Lou Hodges W9IL at (618)-533-4724, or write to CWA, Inc., PO Box 1166, Centralia IL 62801.

DEERFIELD NH
MAY 12

The Hosstraders will hold their Spring Tailgate Hamfest on Saturday, May 12, 1984, sunrise to sunset, at the Deerfield NH Fairgrounds. Admission is $2.00, including tailgaters and commercial dealers. For a nominal fee, there will be Friday-night camping for self-contained rigs. No one will be admitted before 4:00 pm Friday and no spaces will be reserved. Profits will benefit the Boston Burn Unit of the Shriners' Hospital. Last year's total donation was over $4,700. For further information or a map, send an SASE to Norm WA1IVB, RFD Box 57, West Baldwin ME 04091; Joe K1RQG, Star Route Box 56, Bucksport ME 04416; or Bob W1GWU, Walton Road, Seabrook NH 03874.

The Livonia Amateur Radio Club will host the 1984 ARRL Michigan State Convention on June 29-30, 1984, on the campus of Schoolcraft College, 18600 Haggerty Road at Seven Mile Road, Livonia MI (22 miles northwest of downtown Detroit). Schoolcraft is easily accessible via Interstates 75, 275, 96, or 94. The Swap-N-Shop will be in the main gymnasium, and one of the two parking lots will be set aside for trunk sales. Major exhibitors will be in the swap area, if requested. Exhibitors' setups will be on Friday, June 29th, from 12:00 noon until 10:00 pm, and the displays will be open on Saturday, June 30th, from 8:00 am until 5:00 pm. There will be security provided on Friday night. For more information, write Wayne W. Wiltse K8BTH, General Chairman, 1984 ARRL Michigan Convention Committee, 14468 Bassett Avenue, Livonia MI 48154.

SWIFT CURRENT SASK
JUN 30

The Saskatchewan Hamfest will be held on June 30, 1984, in Swift Current SASK. Registration will be the evening before. Features will include contests, displays, a ladies' program, and a banquet. For more details, contact the Saskatchewan Hamfest Committee, Box 6, Swift Current SASK S9H 3V5, Canada.

OAK CREEK WI
JUL 7

The South Milwaukee Amateur Radio Club will hold its annual swapfest on Saturday, July 7, 1984, from 7:00 am to approximately 5:00 pm, at the American Legion Post #434, 9327 South Shepard Avenue, Oak Creek WI 53154. Admission is $3.00 per person and includes a "Happy Hour" with free beverages. Parking, a picnic area, hot and cold sandwiches, and liquid refreshments will be available. There will be free overnight camping. Talk-in on 146.94 MHz FM. For more details, including a local map, write South Milwaukee Amateur Radio Club, PO Box 102, South Milwaukee WI 53172.

BOISSEVAIN MAN CAN
JUL 14-15

The 21st annual International Hamfest will be held on July 14-15, 1984, at the International Peace Garden between Dunseith ND and Boissevain MAN. Activities will include transmitter hunts, mobile judging, and a CW contest. Excellent camping facilities will be available. For more information, contact William W. Bosch WD0EMY or Stanley E. Kittelson WD0DAJ, Box H, Dickinson ND 58801.

LOUISVILLE OH
JUL 15

The Tusco Amateur Radio Club (W8ZX) and the Canton Amateur Radio Club (W8AL) will present the 10th annual Hall of Fame Hamfest on Sunday, July 15, 1984, at the Nimishillen Grange, 6461 Easton Street, Louisville OH. Admission is $2.50 in advance and $3.00 at the gate. Tables are for rent on a reserved basis. Talk-in on 146.52/.52 and 147.71/.12. For reservations or more information, write Butch Lebold WA8SHP, 10877 Hazelview Avenue, Alliance OH 44601, or phone (216)-821-8794.

LAPORTE IN
JUL 15

The combined LaPorte-Michigan City Amateur Radio Clubs will sponsor their Summer Hamfest on Sunday, July 15, 1984, from 8:00 am to 2:00 pm, at the LaPorte County Fairgrounds, State Road 2, west of LaPorte IN. The donation is $3.00 at the gate. Good food, cold drinks, and paved outdoor parking will be available. For reservations for indoor tables (40¢/foot), write PO Box 30, LaPorte IN 46350.

GLACIER PARK MT
JUL 20-22

The Great Falls Area ARC will present the 50th annual Glacier-Waterton International Hamfest on July 20-22, 1984, at Three Forks Campground on the southern edge of Glacier National Park. Pre-registration is $8.50 and includes Saturday-night dinner (bring own meat and utensils) and Sunday-morning breakfast. Talk-in on .52 and .34/.94. For more information, send an SASE to Shirley Smith KC7OA, 1822 14th Avenue South, Great Falls MT 59405.

BEAVERTON OR
JUL 27-29

The Willamette Valley DX Club will hold the 1984 DX Convention on July 27-29, 1984, at the Greenwood Inn, Beaverton OR. For further information, write Bob Herndon W7XN, 607 Andover Place, Portland OR 97202, or phone (503)-232-2740.

HOUGHTON MI
JUL 28

The Copper Country Radio Amateur Association will host the 1984 Upper Peninsula Hamfest on July 28, 1984, at the Memorial Union Cafeteria on the campus of Michigan Technological University, Houghton MI. For further information, write Howard Junkin N8FHF, Co-Chairman, UP Hamfest, 106 West South Street, Houghton MI 49931, or phone (906)-482-4630.

WEST FRIENDSHIP MD
JUL 29

The Baltimore Radio Amateur Television Society (BRATS) will present the BRATS Maryland Hamfest and Computerfest on Sunday July 29, 1984, at the Howard County Fairgrounds, Route 144 at Route 32, adjacent to Interstate 70, West Friendship MD, about 15 miles west of the Baltimore Beltway (695). Table sales are by advance reservation only; indoor tables along the wall with ac are $20.00 each and indoor tables in the center of the floor without ac are $10.00 each. Quantity discounts and booths are available. There will be plenty of outdoor tailgating and RV hookups will be available. Dealer setups begin Saturday at 2:00 pm with overnight security provided. Talk-in on 146.76 (−600), 147.03 (+600), and .52 simplex. For table reservations and more information, write BRATS, PO Box 5915, Baltimore MD 21208, or call Mayer Zimmerman W3GXK at (301)-655-7812.

LAFAYETTE IN
AUG 19

The Tippecanoe Amateur Radio Association will hold its 13th annual hamfest on Sunday, August 19, 1984, beginning at 7:00 am, at the Tippecanoe County Fairgrounds, Teal Road and 18th Street, Lafayette IN. Tickets are $3.00. Features will include a large flea market, dealers, and refreshments. Talk-in on .13/.73 and .52. For advance tickets and more information, write Lafayette Hamfest, Route 1, Box 63, West Point IN 47992.

CHEROKEE OK
AUG 26

The 2nd annual Great Salt Plains Hamfest will be held on August 26, 1984, from 9:00 am to 5:00 pm, at the Community Building on the south side of the Great Salt Plains Lake in north-central Oklahoma. Features will include technical forums, organizationals meetings, free swap tables, refreshments, Novice exams, and a noon pot-luck dinner. Overnight camping and RV hookups are available at the Lakes State Park. Talk-in on the 147.90/.30 Salt Plains repeater. For more information, write Steven Walz WA5UTO, Box 222, Cherokee OK 73728, or phone (405)-596-3487.

PARAMUS NJ
OCT 14

The Bergen ARA will hold a Ham Swap 'n' Sell on October 14, 1984, from 8:00 am to 4:00 pm, at Bergen Community College, 400 Paramus Road, Paramus NJ. There will be tailgating only; bring your own table. Admission for sellers is $4.00; buyers will be admitted free. Thousands of spaces will be available. Talk-in on .79/.19 and .52. For more information, write Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855, evenings only.

HAM HELP

I am looking for a 3-inch-square meter that was used in the Collins 302C3 wattmeter. Also a Collins 75S3A.

Max R. Otto W0LFF
733 West Benton Street
Iowa City IA 52240

I am requesting any information on Tesla coils. I need this for a science project. Any articles on how to build a Tesla coil will be greatly appreciated.

Kent Barrett
141 Gatone Drive
Hendersonville TN 37075

I am looking for a synthesizer compatible with a Heathkit HW-202 2m FM transceiver. Xtals are Freq./24 for Tx and Freq. – 10.7/3 for Rx. I am also looking for a Drake FS-4 synthesizer. Any manuals available for such devices would also be appreciated.

Allen Cole N4JRI
PO Box 11282
Richmond VA 23230-1282

Regarding CB to 10 meters: I would like information on the conversion of a Pace-Sidetalk 1000M.

L. Latham N5FJK
2500 Flamingo Lane
Altus OK 73521

I need a schematic or other info for a Simpson 260 series 5 and series 3A, RCA WV77E, and EICO 232. I will pay shipping and copying costs.

Fred "Al" Wasielewski WA2VJL
PO Box 1382
San Benito TX 78586

Hammarlund HX-50 or 50A SSB transmitter: Looking for info on 160-meter kit, part #PL26880-G1 or G2, which adds 160 meters to this rig. Will consider junked HX-50 or 50A with 160 meters installed, as parts source.

John F. Sehring WB2EQG
PO Box 1872
Wayne NJ 07470

Need schematic and/or manual for AM-COM S 2-25 2m xcvr. Will pay all expenses.

Manos G. Darkadakis SV1IW
Box 23051
112 10 Athens, Greece

I am looking for help with the problem of interfacing a Heath SS-9000 transceiver with a VIC-20 or Commodore 64. I have an RS-232 interface on the computer and have configured it as follows:

RS-232 Serial Output to Soutput on 9000
RS-232 Serial Input to Sinput on 9000
Request to send to Clear to send on 9000
Data terminal ready to Data set ready on 9000
Data set ready to Data terminal ready on 9000
Signal ground to signal ground

I am using Victerm 1 software, and needless to say, this configuration is not working. I live on the desert here in California and am about 150 miles from San Diego and 200 miles from Los Angeles. There are no users groups anywhere around this area, so I don't know where to turn for help.

I am willing to pay any reasonable charge for help with this matter.

Dick Ham N6IUK
PO Box 1014
Brawley CA 92227

I would like to contact other hams who have what I term "sophisticated" computerized RTTY—programs that emulate fancy dedicated equipment (e.g., Hal 3100, etc.) and allow mailbox ops, the sending of a file to/from disk, etc. Info on such programs and their resident computers and required interfacing would be most greatly appreciated.

I am interested both for my own personal info (i.e., purchase) and because there is no single source of data on what is available for which computer and what the capabilities and limits are. I intend to compile and publish that source.

John Palesa WB9JPH/5
314 Cedar Bend Drive
Midwest City OK 73130

I need a schematic for a Commodore VIC-20 computer. I'll pay any reasonable charge.

Warren J. Koppy WB0KIS
903 Mound Street
St. Paul MN 55106

I need a schematic for a Radio Mfg. Engineers, Inc., serial no. CM1 receiver. I will pay for copying costs.

CHOOSING A PROGRAMMING LANGUAGE

Computer users are always debating which programming language is best. In my opinion, it is impossible to say which one is "best." While I tend to use PL/I-80 by Digital Research for most of my programming needs, I certainly would not use it for everything. For some applications, particularly for short programs that are used once to perform a mathematical calculation, Basic is the best choice. For many amateur-radio and electronics applications, programs are written and run only once to calculate a particular value. Once the needed value is obtained, the program will never be run again.

The traditional way of comparing languages is through the use of a benchmark—taking the same algorithm and translating it into a number of different languages. The execution times (how long it takes to run) are then compared and the fastest one is considered the best. Unfortunately, this method doesn't take the amount of time needed to *write* the program into account. Also, some languages are fast while doing one type of calculation and slow for another. PL/I-80 provides a good example of this! For binary calculations it is extremely fast, but when dealing with BCD or floating-point numbers, it creeps.

To demonstrate that execution times alone are not a good way of comparing languages, I have put together a benchmark comparison of 7 programming languages: four versions of Basic and one each of Pascal, PL/I-80, and Cobol. In this comparison, I have recorded the amount of time it took to write the program, from the moment I sat down at the keyboard to the end of the first working run. I also did another sneaky thing: I purposely chose a problem that is not efficiently calculated in microcomputer implementations of Pascal, PL/I, and Cobol.

Basic

The Basics I used were Applesoft, Microsoft Basic-80 (running under a 2-MHz CP/M system), Atari Basic, and T.A.S.C. (a compiled Applesoft marketed by Microsoft). The program, which calculates the sum of the integers from 1 to 1000, is shown in Listing 1. Line 10 is there to permit timing—timing starts when RETURN is hit in response to the INPUT statement and stops when the result appears on the display. (In the Atari version, I added "5 DIM A$(1)". This was needed because Atari Basic handles strings differently.)

Writing time for Applesoft, Microsoft, and Atari Basics were close, at 38, 44, and 50 seconds respectively. Execution times were 3.71 seconds for Applesoft, 6.01 seconds for Microsoft Basic-80, and 5.75 seconds for Atari Basic. It is interesting to note that although the Atari's 6502 MPU runs at 1.8 MHz as compared with Apple's 1.024-MHz clock, Atari Basic is *slower* by a factor of 84%. This example shows that CPU speed isn't always a good criterion with which to compare computers.

T.A.S.C., which stands for The AppleSoft Compiler, had a "writing time" of 2 minutes, 7 seconds. The extra time is because the compiler checks the program's syntax and converts it to machine language *before* any code is actually executed. In contrast, Basic interpreters (i.e., Applesoft) check syntax and execute the code a line at a time. Benefits are realized at execution time; the program took only 1.56 seconds to execute—237% faster than Applesoft and 385% faster than Microsoft Basic-80!

```
10 INPUT A$
20 FOR X = 1 TO 1000
30 S = S + X
40 NEXT X
50 PRINT S
```

Listing 1. Basic.

```
PROGRAM ADD;

   VAR SUM:INTEGER[6];
       IDX:INTEGER;
       X   :CHAR;

  BEGIN (*ADD*)

    READLN (X);

    SUM := 0;

     FOR IDX := 1 TO 1000 DO
        SUM := SUM + IDX;

    WRITELN (SUM)

  END.
```

Listing 2. Pascal.

```

Listing 4. Cobol.

Which Basic is best? Certainly, the compiled version is the fastest as far as execution time. However, it took much longer to get the program ready for execution. For this reason, when writing a program to perform a calculation that has to be done once, a compiled Basic is not worth the extra effort. On the other hand, if you have to do a few hundred calculations, the additional speed would be an advantage.

PL/I, Pascal, and Cobol

Because they are compiled, PL/I, Pascal, and Cobol would suffer from the same disadvantages as T.A.S.C. This is not too surprising. What is surprising is that all three of them were slower in *execution* speed than Applesoft Basic. In fact, PL/I and Cobol were slower than Basic-80.

Listing 2 shows the Pascal version of the program. Notice that it took 11 lines as compared to Basic's 5 lines, making it 220% longer. It took 5 minutes, 7 seconds to write, compile, and run the program; execution time alone was 4.52 seconds. The version of Pascal I used was UCSD Pascal version 1.1 running on a 2-MHz Z-80 computer. UCSD Pascal is not a true compiler. It converts the program into an intermediate language called P-code, which is then interpreted.

Don't get the idea that Pascal isn't a good language. It contains many features that would be difficult, if not impossible, to code in Basic. It also allows for elaborate records, structures, and sets. Unlike Basic, it is a fairly standard language. I can give the program in Listing 2 to almost any Pascal compiler and it would run with no difficulty.

PL/I-80 produced some disappointing results (Listing 3). It took 4 minutes, 49 seconds to write, compile, link, and run the program. Execution time alone was 8.13 seconds, slower than the slowest Basic (Basic-80) in our benchmark.

The PL/I-80 compiler is marketed by Digital Research and is my favorite microcomputer language. It is not efficient when calculating fixed-point binary numbers—usually about 35 times faster than the best Basics. Unfortunately, fixed-point binary numbers must be in the range of −32788 to +32787. This is not enough for our benchmark program, which produces a result of 500500. The size of this result forced me to use fixed decimal numbers (which are not computed as efficiently), slowing the program down considerably.

Another factor that slowed PL/I-80 is the nature of the language. PL/I-80 allows mixing of types. For example, the statement T=T+'1' is perfectly valid—the string constant '1' is converted into a number and added to T. The ability to convert from one type (string) to another type (numeric) adds considerable overhead to PL/I programs and, not surprisingly, slows them down. It is these same time-wasting features that can be lifesavers in many programming applications and make for more efficient programs.

The slowest language in our benchmark is Cobol-80 made by Microsoft. Cobol is a business language and is best at file handling and printing tables of decimal numbers. Speed in calculation is not one of Cobol's strong points.

Writing, compiling, linking, and running the Cobol program in Listing 4 took 9 minutes and 27 seconds. Execution time alone was 22.45 seconds—373% slower than the Basic-80 and 1439% slower than T.A.S.C. It is clear that Cobol-80 is not a good choice for numerical calculation. However, when working with data files or printing out financial reports, paychecks,

PC-1 - TRS 80 - POCKET COMPUTER.
33 SECONDS. X = 1 TO 1000

✓See List of Advertisers on page 114

or accounts receivable, it is a good choice.

Conclusions

Which language is best? As you can see, it is hard to answer that question. You've probably heard that Pascal is "better" than Basic, or that PL/I-80 is the fastest compiled language for microcomputers, but as you can see from benchmark results, this is not always the case. In general, for a long program, PL/I or Pascal will execute faster than any Basic. However, when writing a program to do a specific mathematical calculation, Basic is often the best choice. It is certainly quicker to get a Basic program running than a PL/I program—no compiling or linking is necessary.

Incidentally, the best choice is sometimes no computer program at all! Let's take another look at the problem solved by our benchmark program: finding the sum of the numbers from 1 to 1000. The program calculates this by adding 1 + 2 + 3 + 4 + . . . + 1000. However, it can also be looked at as adding (1000 + 1) + (999 + 2) + (998 + 3) + . . . + (501 + 500). You'll notice that the number within the parentheses always adds up to 1001, and you are adding this to itself 500 times. By multiplying 1001 by 500, which can easily be done in one's head, one comes up with 500500. The same method can be used to find the sum of any other series of numbers. For example, the sum of the integers from 1 to 250 is equal to 251 times 125, or 31375.

When I first discussed programming languages a few months ago, I was surprised by the amount of interest the subject generated; my post-office box was overflowing! I hope this column clears up some of the mystery surrounding the various languages available to the microcomputer user.

FREE SATELLITE PREDICTION BULLETINS

Free satellite-orbit-prediction charts are available from NASA on the following amateur-radio satellites (NASA Identification Number is in parentheses): OSCAR 9 (1981-100B), RS-3 (1981-120A), RS-4 (1981-120D), RS-5 (1981-120C), RS-6 (1981-120F), RS-7 (1981-120E), RS-8 (1981-120B), and OSCAR 10 (1983-58B).

In order to fully understand the bulletins, ask for the "Format Explanation of the NASA Prediction Bulletin." Also request the "Map Overlay Method of Hand Computing Station Predictions." This will show you how to determine viewing angles and times from your station.

Send your request to: R. V. Tetrick, Head, Project Operations Branch, NASA, Goddard Space Flight Center, Greenbelt MD 20771. (Thanks to Carl S. Zelich AA4MI for this information.)

CORRECTIONS

Herewith a revised negative for the circuit board in the article ("Build the NASA Beeper") which I sent to you and which was published on page 88 of the March, 1984, issue of *73*. In checking the proofs of the board, I inadvertently compared it to a different earlier negative which was in error. Please accept my apologies.

Nicholas Van de Sande KQ4G

HAM HELP

I want a program for a Commodore 64 where I can put in my latitude and longitude and the other station's latitude/longitude and get the other station's distance in miles.

I have tried converting programs for this written for the Radio Shack models 1 and 3, Heath, and Hewlett-Packard 9845 and cannot get any to run. Also, one written for the VIC-20 didn't work either.

Gary Payne KE6CZ
1347 E. Dakota
Fresno CA 93704

I need the schematic and operating manual for the Knight TR-106 6-meter transceiver with the model V-107 remote vfo. Any help will be appreciated.

P. J. Mikula KA8RZL
70 Clay St.
Manistee MI 49660

I want someone to have a sked with me to increase my CW speed. Must use keyboard and start at 25 wpm. For more info, call (304)-983-2157.

Roger Vankirk KX8Y
Rt. 2, Box 388X
Morgantown WV 26505

I would like to hear from anyone who has modifications to put the Ten-Tec Omni on 10-meter FM.

Stephen J. O'Malley N2CLE
140-26 Poplar Ave.
Flushing NY 11355

I need help on the Galaxy (Hy-Gain) R-530 solid-state general-coverage receiver. The phase-lock oscillator is not working. I need any information on parts sources, alignment/troubleshooting data, or individuals who can repair. If anyone wants to start an R-530 club or newsletter or knows of same, contact me.

Jim Turner K5YZS
103 Karla Drive
Whitehouse TX 75791

I need a service manual or schematic or copy of same for a Yaesu FM FT-202R handie-talkie. Also need crystals for 2 meters or charger.

Cyril T. Wolff WA7LOV
S. 5507 Marshall Road
Spokane WA 99204

I need a schematic and operation manual for DuMont 274 scope. I will gladly pay copying costs and postage.

Robert A. Johnson N7CFX
833 E. Gwinn Pl.
Seattle WA 98102

I have recently purchased a Radio Shack TRS-80 model 100 and would like to know if there is any ham software available for it commercially. I am particularly interested in any CW send/receive and RTTY software and would appreciate having the names of any companies that might have such systems.

Information about software for other computers that run Basic would even be helpful, as I think that I could adapt it for the model 100.

David C. Eanes N4AZI
4866 Drusilla Lane
Baton Rouge LA 70809

Wanted: bfo transceiver for a Hammarlund SP-600-JX-1 s/n 4528 (R274C/FRR 650), part number 31160-1. Also have a box of coils for National RAO-6 which I will donate to the first taker.

Peter Doherty W1UO
PO Box 291
Port Townsend WA 98368

About 25 years ago, Emerson (I believe) came out with a portable radio powered by batteries and/or a built-in solar cell. They only made a few. (I wonder why?) It worked well with both sun and artificial light. I would like the name and address of the manufacturer since I want one of these old radios.

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

TEN-METER FM AWARDS

Sponsored by the North Whidbey Island Repeater Association (NWIRA).

All contacts, to be valid, must have been made on or after January 1, 1981. Crossmode contacts do not count. Contacts must be 2-way ten-meter FM.

Special endorsements can be made for all-mobile, all-simplex, and single-frequency accomplishments and contacts made within a single day, week, month, or year.

Note: Members of the NWIRA monitor 29.600 MHz, as well as the area repeater on 29.640 MHz (an 1800-Hz tone or whistle is required to access).

Do not send QSL cards! Forward your list of contacts showing the date, time, and frequency of each QSO and provide a brief station description, along with the fee of $4.00 for each award to: Ten-Meter FM Awards Program, 2665 North Busby Road, Oak Harbor WA 98277.

Worked All Districts Award

To qualify, applicants must work one ten-meter FM station in each of the ten US call districts.

Worked All States Award

Applicants must work a minimum of fifty US states on ten-meter FM.

Centurion Award

This award requires the applicant to work a minimum of 100 stations on ten-meter FM.

DX Decade Award

Applicants must work a minimum of ten DX stations outside the fifty US states and Canada on ten-meter FM.

North American Award

To qualify, applicants must work all ten US call districts, a minimum of six Canadian provinces and/or territories, and at least four DX countries within the North American continent (other than the US and Canada) on ten-meter FM.

OPERATING ACHIEVEMENT AWARDS FROM *A5 MAGAZINE*

Fast-Scan ATV Award

"Getting the amateur television station operating is an award in itself!" This award certificate recognizes the "first" amateur television two-way contact. Endorsements for DX mileage and color ATV are available. Contacts via ATV repeaters are allowed. Award inscriptions are made around the border of the *A5* block. Black and white, 8" × 10".

Master Scanner *A5* SSTV Award

This award certificate recognizes the serious SSTVer. Entry level is 100 two-way SSTV contacts. Endorsements for 500, 1000, 1500, 2000, etc., are available. Special endorsement for color SSTV is available with verified print copy. A must for every SSTVer! Gold, 8" × 10".

Specialized Communications Achievement Award

This award recognizes accomplishments in ATV, MSTV, NBTV, SSTV, fax, RTTY, EME, microwaves, and satellites. Entry levels are contacts over 100 miles on ATV. Special-event ATV projects, 25 DX country contacts on SSTV, reception of HF MSTV or fax signals via amateurs, microwave DX, 10 DX foreign countries via EME, 10 two-way contacts on an amateur satellite, and 25 DX countries on RTTY are required, with special endorsements available for additional contacts. Certificates are numbered as received; They are gold, 8" × 10", and suitable for framing.

Worked All States SSTV

Work all 50 states (including Hawaii and Alaska) with exchange of callsign and signal report in video. A special WAS map is available to color in the states as you get them. This is an ongoing award not limited to the annual contest. Special endorsements are available for multiband WAS.

Worked All States RTTY

Work all 50 states (including Hawaii and Alaska) with log copy verification. This is an ongoing award not limited to the annual contest. Special endorsements are available for multiband WAS.

Good Image Award

Awarded at the Dayton Hamvention each year, the Good Image Award is presented to the individual or group of individuals who contributed to the advancement of the *A5* code of communication by technical achievement or public awareness. Top-of-the-line award!

All *A5 Magazine* awards require subscription-label information date codes. Enclose $1.00 for the cost of the award certificate and 50 cents postage for return mailing (envelope is provided). Allow 2-3 weeks for verification and mailing. Send all requests to Awards Manager, *A5 Magazine*, PO Box H, Lowden IA 52255-0408. Winners of awards will be published on a regular basis in *A5 Magazine*.

CENTRAL STATES VHF SOCIETY OPERATING AWARDS

At the 1981 Central States VHF Conference in Sioux Falls, South Dakota, in August, the Central States VHF Society formally announced its new operating awards program with three colorful awards for VHF/UHF/SHF bands.

Each award was designed to stimulate activity on the bands above 144 MHz. The differences in the awards as well as the variety of endorsements available provide challenging but achievable goals regardless of the station's geographic location or capabilities.

The awards are open to all amateurs—not just CSVHF Society members. To receive rules and application sheets, send a legal-size SASE (with two stamps) to Bob Taylor WB5LBT, 10715 Waverland, Baton Rouge LA 70815.

General Rules—All Awards

The awards described below are available to all amateurs worldwide who submit details of the required contacts (on the separate award application detail sheet) and have the accuracy of the application certified by a local member in good standing of the CSVHF Society. In addition to the basic awards, certain optional endorsements are available as described below and on the application cover sheet.

For all awards, direct two-way communication must be established on amateur-radio bands of 144 MHz and above. Minimum contact requirements are the exchange of callsigns and signal reports (or other mutually understood information) and receipt of acknowledgement that both stations have received this information. All contacts for each award must be on the same band.

Contacts must be made from the same location or from other location(s) licensed to the application, no two of which are more than 50 miles apart.

Contacts for the VUCC and WHG awards may be made over any period of years, with no starting date, but numbered certificates will be issued only to those who have made the required contacts after August 1, 1981. 1K Coverage Award contacts must be made during any two consecutive months after August 1, 1981.

Contacts made through "repeater" devices or any other power-relay method do not count toward any of the awards. In addition, no crossband contacts are permitted.

False statements on the application cover sheet or on the detail sheet(s) shall result in immediate disqualification for any of the awards.

Remember, you do not have to be a member of the CSVHF Society to apply for an award. However, if you wish to join, send the $5.00 membership dues to: Ted Mathewson W4FJ, CSVHF Society Secretary, 1525 Sunset Lane, Richmond VA 23221. Please do not send dues with awards applications.

VUCC

The VUCC (VHF/UHF Century Club) award simply requires contacts with 100 different amateur stations. Optional endorsements for working additional stations in increments of 25 (e.g., 125, 150, 175, etc.) or for making all the contacts during a single calendar year (Jan. 1 through Dec. 31) are available only if all the contacts were made on the same mode of propagation (sporadic E skip, EME, meteor scatter, or aurora).

1KCA

The 1K Coverage Award requires contacts of sufficient number and distance such that the sum of the QSO points for all the contacts during each of any two consecutive calendar months is equal to or greater than 1000. The QSO points for any given contact are the band points multiplied by the distance points. The band points are determined as follows: 144 = 2, 220 = 5, 432 = 4, 1295 = 5, 2300 = 10, 3300 = 15, 5650 = 25, and 10 GHz and up = 50. The distance points are simply the number of 1-degree-by-1-degree "grids" (see definition under WHG Award) you are away from the other station's 1-degree-by-1-degree grid. For example, if the station is in the next grid over from yours, the distance point for the contact is 1; if it is two grids over, the distance points are 2, etc. Contacts in your own grid have a distance point value of 1. For stations which are not in a grid directly north, south, east, or west of yours (i.e., off at an angle), the distance points have to be calculated. In such cases, the distance points are equal to the square root of the sum of the latitude difference squared and the longitude difference squared, where the differences in latitude and longitude are measured in numbers of whole 1-degree-by-1-degree grids. The resulting distance points are to be rounded off to the nearest tenth. Only one contact with a given station per GMT day counts toward this award, and EME contacts do not count. There are no additional endorsements available for this award.

WHG

The WHG (Worked Hundred Grids) award requires contacts with stations in 100 different 1-degree-by-1-degree geographic grids. The grids are defined as the area bounded by integral values of latitude and longitude. For example, a station whose longitude is 112 degrees 32 minutes 15 seconds west and latitude is 37 degrees 25 minutes 16 seconds north would be in the grid 112W37N. All stations are urged to include their latitude and longitude and/or equivalent recognized QTH locator code on their station cards to assist others in determining their grid. If you have to determine the other station's grid yourself, it can be done easily by looking up the town location in any good road atlas and then locating the position on a larger map which shows the 1-degree lines of latitude and longitude. Two such maps are listed here:

1. "Map 2-A" comes in two halves (54" × 80" assembled) and is available for $3.00 postpaid from: Branch of Distribution, US Geological Survey, Federal Center, Denver CO 80225. Shown are counties, county seats, capitals, and cities larger than 500,000.

2. Rand McNally's "Contemporary United States" measures 36" × 54" and is available through bookstores for $2.95. The map does not show counties but does include major highways, a number of cities and towns, and 3 degrees more latitude in Canada than the USGS map.

Optional endorsements are available for working additional 1-degree-by-1-degree grids in increments of 25 (e.g., 125, 150, 175, etc.) or for working all the different grids in a single calendar year.

MARCO POLO

We are proud to announce that the Catanzaro, Italy, chapter of ARI, Associazione Radioamatori Italiani, issues an international DX award called Marco Polo, in order to commemorate the long and difficult travels of this Italian explorer throughout Asia, starting from Venice in the XIII century.

This award is available to any OM/SWL who is a member of the IARU section of his own country and exemplifies the ham spirit through a reenactment of the trail of Marco Polo over the airwaves, by establishing contacts with the various areas mentioned or crossed by the famous Venetian.

A brief summary of the rules is listed below. The cost is $4.00 plus $1.00 for mail coverage; endorsements cost $1.00. For a complete copy of the rules or any inquiries, contact Award Manager I8QLI, Gianni Verdegiglio, PO Box 19, 88100 Catanzaro, Italy.

We think that a large number of DX hunters will be interested in qualifying for this diploma. This award requires skill, diligence, and unrelenting effort in pursuing by radio the ancient trail of Marco Polo. Here's hoping that this award will enhance your pleasure for DX.

Summary of the Rules

1. This award is available to any OM/SWL member of an IARU chapter.

2. The contacts must be established with countries described by the Venetian explorer Marco Polo in his book, *Il Milione* (*The Million*)—see box, following page.

3. All modes are valid, except crossband.

4. Only one QSO will be considered for each country; the operations must be valid for DXCC, in accord with the rules of ARRL.

5. Various scores are attributed to differ-

LIST OF COUNTRIES—MARCO POLO AWARD

Areas or Countries	Prefixes	Points
Central Greece	SV4	4
Israel	4X, 4Z	1

ent countries, in order to remark the skill or the interest: countries referred to same geographical area are scored only once (see list).

6. Contacts are valid starting from January 1, 1978.

7. The award is issued in five classes: 1. Base award, at least 60 points—3-color diploma; 2. Silver award, at least 80 points—3-color diploma, shield; 3. Gold award, at least 95 points—3-color diploma, shield; 4. Honor Roll, at least 110 points—3-color diploma, medal; and 5. Top Honor Roll, at least 125 points—3-color diploma, medal. Endorsements are available each year for class enhancement.

8. QSO listed with band, mode, date, and GMT and signed by at least two hams that are members of DXCC or WAZ must be sent to Award Manager I8OLI, Gianni Verdegiglio, PO Box 19, 88100 Catanzaro, Italy. QSL front/back photocopies are accepted in substitution of signatures; however a list must be provided.

9. The cost of each class of diploma is $5.00 ($4.00 plus $1.00 for mail coverage). Any endorsement must be accompanied by a new general list, number of diploma, and $1.00 plus SAE.

10. The award manager may request original material or photocopies to confirm validity.

11. Alterations, false declarations, or other irregular operations will be considered cause for disqualification.

12. Inquiries should be addressed to ARI, Council of Chapter, Box 200, 88100 Catanzaro, Italy. No other judgment will be considered.

ONTARIO BICENTENNIAL AWARD

Sponsored by the Radio Society of Ontario, Inc. Contacts valid only for January 1 to December 31, 1984.

VE3 Stations

Contact 200 different VE3 or portable VE3 stations. One point each.

Other VE, VO, VY

Stations contact 100 different VE3 or portable VE3 stations. Two points each.

DX Stations Including USA

Contact 20 different VE3 or portable VE3 stations. Ten points each.

Any mode or band endorsed at your wish. Special seals for each 200 extra points. If VE3 stations are using special call or prefix, they count double. No QSL cards necessary. Send certified log data and $1.00 or 3 IRCs to: VE3LSS, Bicentennial Project, Listowel District Secondary School, Geography Department, Listowel, Ontario, Canada N4W 2M4.

1984 Special-Event Stations

VE3SAS—St. Catharines, Ontario, Canada, bicentennial station. QSL via Dave Digweed VE3FOI, 12 Frederick Street, St. Catharines, Ontario, L2S 2S2.

VE3VM—August 4, 5, and 6, special operation from Burgyon Woods, St. Catharines, Ontario, by members of Niagara Peninsula ARC. QSL to PO Box 692, St. Catharines, Ontario, L2R 6Y3.

USA amateurs can use US stamps on SASE, mail will be sent from Niagara Falls NY USA; this is for special-event stations only.

ARMED FORCES DAY 1984 "MEETING THE CHALLENGE"

This year's observance of Armed Forces Day, set for Saturday, May 19, marks the 35th anniversary of communications tests between amateur-radio operators and military communications systems. Since 1950, this event has been scheduled during the month of May and has emphasized a continuing climate of mutual assistance and warm esteem.

Featured highlights of the nationwide celebration are the traditional military-to-amateur crossband communication test and a message-receiving test. The crossband test will include operations in continuous wave (CW), single sideband voice (SSB), radioteletype (RTTY), and slow-scan television (SSTV). The receiving test consists of two special Armed Forces Day messages from the Secretary of Defense, one transmitted using the CW mode followed by the second transmitted in the RTTY mode.

These tests give both amateur-radio operators and shortwave listeners (SWLs) the opportunity to demonstrate their individual technical skills. Special commemorative acknowledgement (QSL) cards will be awarded to those amateur-radio operators achieving a verified two way radio contact with any of the participating military radio stations. Interception of these contacts by SWLs is not acknowledged by QSL cards, however, anyone who receives and accurately copies the Armed Forces Day CW and/or RTTY message from the Secretary of Defense can qualify to receive a special commemorative certificate from the Secretary.

Crossband Contacts

The military-to-amateur crossband operations will be conducted from 19/1300 UTC to 20/0245 UTC, May, 1984. East-coast stations commence operations at 19/1300 UTC and west-coast stations commence operations at 19/1800 UTC, May, 1984. Military stations will transmit on selected military frequencies and listen for amateur-radio stations on those portions of the amateur bands as indicated in Table 1. The military operator will announce the specific amateur-band fre-

Station	Military Frequency	Emission	Amateur Band

Table 1.

quency being monitored. Duration of these contacts should be limited to three minutes.

CW Receiving Test

The CW receiving test will be conducted at 25 words per minute. The broadcast will be a special Armed Forces Day message from the Secretary of Defense to any amateur-radio operator or shortwave listener desiring to participate. A 10-minute call for tuning purposes will begin at 20/0300 UTC, May, 1984. The Secretary's message will be transmitted at 20/0310 UTC, May, 1984 from the stations on the frequencies listed in Table 2.

Radioteletypewriter Receiving Test

The radioteletypewriter receiving test will be transmitted at 60 words per minute using 170 Hertz (narrow) shift. A 10-minute call for tuning purposes will begin at 20/0335 UTC, May, 1984. The special Armed Forces Day message from the Secretary of Defense will be transmitted at 20/0345 UTC, May, 1984. Transmission will be from the same stations on the same frequencies as previously listed for the CW receiving test.

Submission of Test Entries

Transcriptions of the CW and/or RTTY receiving tests should be submitted "as received." No attempt should be made to correct possible transmission errors. The time, frequency, and callsign of the military station copied as well as the name, callsign, and address (including zip code) of the individual submitting the entry must be indicated on the page containing the test message. Each year, a large number of acceptable entries are received with insufficient information or the necessary information is attached to the transcription and is separated, thereby precluding the issuance of a certificate. Entries must be postmarked no later than May 26, 1984, and submitted to the respective military commands as follows:

Stations copying AIR send entries to: Armed Forces Day Test, 2045CG/DONJM, Andrews AFB DC 20331.

Stations copying NAM, NAV, or NPG send entries to: Armed Forces Day Test, HQ Navy-Marine Corps MARS, 4401 Massachusetts Ave. NW, Washington DC 20390.

Stations copying WAR send entries to: Armed Forces Day Test, Commander, 7th Signal Command, ATTN: CCN-PO-OX, Fort Ritchie MD 21719.

Table 2.

GLOUCESTER COUNTY NJ

The Gloucester County Amateur Radio Club will operate W2MMD from 1700Z May 4 to 1700Z May 5, to commemorate the club's 25th anniversary. Phone operation in lower portion of General-class bands 10-80, and CW in Novice bands. Commemorative certificate by QSL to GCARC, PO Box 370, Pitman NJ 08071.

SUN DAY

The Florida Solar Energy Center (FSEC) of the State University System of Florida and the Indian River Amateur Radio Club will celebrate Sun Day on May 5 and 6, 1500Z to 2200Z. 5,880 photovoltaic 4-inch-diameter solar cells will provide for heating, cooling, cooking, and amateur-radio operations during this public event, Sun Day.

W4NLX/4 will operate on SSB—7.240, 14.240, 21.370, and 28.518; CW—7.040, 14.040, 21.040, and 28.003; and FM—146.28/.88. A beacon will be on 1296.05 MHz.

For all shortwave listeners and amateur-radio operators, *The Solar Collector*, a quarterly high-technology newsletter, is available free, on request. Also, a multicolor certificate is available. Send a business-size SASE to: FSEC, 300 State Road 401, Cape Canaveral FL 32920.

BALLOON RACE

The Alamance Amateur Radio Club (K4EG) will be operating a special-event station, May 12 and 13, from the site of the Regional Hot Air Balloon Race, Burlington, North Carolina. Each day's operation will be from 1100 to 2200 UTC. Frequencies of operation will be 10 kHz inside the lower General phone portion of 40 and 15 meters, and 7.125 kHz and 21.130 kHz in the Novice bands. An attractive commemorative QSL will be issued to all stations worked for a QSL and an SASE. QSL to: Alamance Amateur Radio Club K4EG, PO Box 3064, Burlington NC 27215.

DOGWOOD FESTIVAL

Fairfield, Connecticut: The Greater Fairfield ARA will operate WB1CQO from 1300 to 2200 UTC, May 12, during the annual Dogwood Festival. A certificate is available for an SASE. Frequencies: 3.975, 7.235, 14.330, 21.420. Contact: Jerry C. Melson KE1A, Greater Fairfield Amateur Radio Association, PO Box 1364 SM, Fairfield CT 06430.

ARMED FORCES DAY AT WEST POINT

On May 12 and 13, 1984, The Meadowlands Amateur Radio Association will be operating at the United States Military Academy at West Point, New York, in honor of Armed Forces Day 1984.

The club will be operating under the club station call N2BMN. Operation will be from 1400Z to 2000Z UTC, May 12, and from 1400Z to 1700Z UTC, May 13. Frequencies will be: SSB—14.310, 7.250, 144.225, and 50.125 MHz, FM—146.550 MHz.

Send a large SASE with $.37 US postage to accommodate an 8½" × 11" certificate of confirmation of QSO to: PO Box 324, Little Ferry NJ 07643.

US AIR FORCE MUSEUM

To celebrate the observance of Armed Forces Day, the United States Air Force Museum will, for the second time, host the operation of an amateur-radio special-event station.

To be housed in the Museum's WWII Nissen Hut, participants will operate under the callsign K8DMZ from 1400Z to 2200Z, Saturday, May 19. Amateur-radio operators will work primarily in General-class phone segments of 75, 40, 20, 15, and 10 meters with periodic excursions to the Novice subbands. FM and SSB operation on the 144-, 220-, and 432-MHz bands is also planned. The specific frequencies to be used will depend upon existing band conditions. To commemorate the event, the museum will issue a special certificate for each two-way contact.

The largest and oldest military aviation museum in the world, the Air Force Museum is located six miles northeast of Dayton at historic Wright-Patterson Air Force Base.

BIG RED ONE

On May 19 and 20, 1984, Armed Forces Day Weekend, the Wheaton Community Radio Amateurs, Inc., will conduct a special event from the First Infantry Division Museum, Cantigny, in Wheaton, Illinois.

The special-event call will be N9BRO. The 24-hour-long event will be on all bands, beginning at 1700Z (GMT) May 19, 1984. Frequencies will be 50 kHz up from the bottom of the General phone bands, 25 kHz up from the bottom of the General CW bands, and 25 kHz up from the bottom of the Novice bands. RTTY on 146.70 simplex, 14.087, and 21.087. 2 meters on 147.54 simplex. Certificate via WCRA, PO Box QSL, Wheaton IL 60189. $1 or 5 IRCs.

ARMED FORCES DAY

In recognition of the 35th annual Armed Forces Day celebration, amateur-radio station W4ODR, located aboard Naval Air Station Memphis, Millington, Tennessee, will be operating on Saturday, May 19, from 1400Z to 2200Z. Plans call for operation on 7.230 (± 10 kHz). CW frequency will be 21.145. 146.52 will be the 2m frequency. It is hoped that operation will be continuous on all bands, but check all frequencies to be sure. Special certificates and QSL cards will be available to those who work W4ODR. QSL to amateur-radio station W4ODR, PO Box 54278, Millington TN 38054. A brief description of the Navy Memphis complex follows.

The 3,400-acre Navy Memphis complex is located 13 miles north of Memphis, Tennessee, and five miles east of the Mississippi River. NAS Memphis is the home of the Chief of Naval Technical Training (CNTECHTRA) and the Naval Air Technical Training Center (NATTC).

CNTECHTRA administers the technical training program for the entire US Navy. Training conducted under the auspices of CNTECHTRA begins with the basic training for all Navy recruits and officer candidates. It continues through various levels of technical skills training and includes instruction for the highly advanced technicians who maintain and operate the extremely technical and sensitive devices found on the Navy's aircraft, ships, and submarines.

Over 3,000 Navy courses of instruction are conducted throughout the command's network of 58 schoolhouses, located at 27 different installations, stretching from the east coast to the west coast, the Great Lakes to the Gulf of Mexico, and across the Pacific to Hawaii. The coordination, supervision, planning research, and guidance for these courses take place at the Millington-based headquarters.

NATTC is the largest single command in the Navy Memphis complex with over 40 different courses of instruction. It stands some 10,000 strong, including students, instructors, and support personnel. The training center's mission is to train selected Navy and Marine aviation personnel in aeronautical technical phases of naval aviation and other related subjects as directed by the Chief of Naval Operations.

PORTSMOUTH SEAWALL FESTIVAL

Portsmouth, Virginia: The Portsmouth ARC will operate W4POX at the Portsmouth Seawall Festival at Portside, May 26, 27, and 28, 1500-2200Z. Frequencies will be around 7230 and 14.290 MHz. For special commemorative QSL, send your card and SASE to: W4POX, PO Box 8503, Portsmouth VA 23703. For QSL and a large commemorative certificate, send your card and a 9" × 12" envelope with two units of first-class postage.

WINO WEEKEND

The Wireless Institute of Northern Ohio (WINO), an organization sponsored by the Lake County Amateur Radio Association, will be on the air with a special-event station to commemorate Ohio Wine Week on Saturday, June 2, and again on Sunday, June 3. On Saturday evening we will be operating between 7 and 11 pm EDST (2300Z June 2 to 0300Z June 3) on 3910 MHz and 7235 MHz. On Sunday afternoon we will be on between 11 am and 4 pm EDST (1500Z to 2000Z) on 7235 MHz and 21380 MHz. The station will be located at an actual winery in Madison, Ohio, and will use the call KO8O. A special 8½" by 11" QSL certificate will be available from: KO8O—WINO Weekend, 7128 Andover Drive, Mentor OH 44060, for a legal-sized SASE.

FAR SCHOLARSHIPS

The Foundation for Amateur Radio, Inc., a nonprofit organization with headquarters in Washington DC, plans to award 15 scholarships for the academic year 1984-85. The foundation, composed of fifty local-area amateur-radio clubs, fully funds two of these scholarships from the proceeds of its annual hamfest. It administers, without cost to the donors, three scholarships for the Quarter Century Wireless Association, two for the Dade (FL) Radio Club and one each for the Radio Club of America, the Richard G. Chichester Memorial, the Young Ladies' Radio League, the Edmund B. Redington Memorial, the Amateur Radio News Service, the Columbia (MD) Amateur Radio Association, the Baltimore (MD) Amateur Radio Club, and the Lewis G. Wilkinson Memorial.

Licensed radio amateurs may compete for one or more of these awards if they plan to pursue a full-time course of studies beyond high school and are enrolled or have been accepted for enrollment in an accredited university, college, or technical school. Most of the scholarships require the applicant to hold at least an FCC General-class license or equivalent. The scholarship awards range from $350 to $900 with preference given in some cases to residents of specified geographical areas or the pursuit of certain study programs.

Additional information and an application form can be requested by a letter or QSL/postcard, postmarked prior to May 31, 1984, from: FAR Scholarships, 6903 Rhode Island Avenue, College Park MD 20740.

The foundation is devoted exclusively to promoting the interests of amateur radio and to those scientific, literary, and educational pursuits that advance the purposes of the Amateur Radio Service.

LATE SPRING QRP SSB ACTIVITY WEEKEND
May 5-6

This is one of several QRP activity weekends held throughout 1984 by the G-QRP-Club of England. The events are intended to promote QRP activity at the times and on the frequencies suggested. Members from other QRP clubs throughout the world and all amateurs interested in QRP are invited to join in at the following times and frequencies:

Times (GMT)	Frequencies
0900-1000	14285
1000-1100	21385/28885
1100-1200	7090
1200-1300	3690
1300-1400	14285
1400-1500	3690
1500-1730	21385/28885
1730-2000	14285
2000-2100	7090
2100-2200	3560
2200-2300	14285

Remember this is an SSB activity and many of the suggested frequencies are outside the USA bands.

FLORIDA QSO PARTY
1400 to 1900 GMT May 5
0001 to 0500 GMT May 6
1500 to 2300 GMT May 6

This is the 18th annual Florida QSO Party sponsored by *Florida Skip*. All amateurs worldwide are eligible and invited to participate. All amateur bands may be used, 160 through 2 meters. All stations will separate phone and CW logs; phone and CW are separate contests. A station may be worked once on each band on each mode. Neither crossband nor crossmode contacts will count for contest credit. Florida stations may work other Florida stations, but for contest points only. Out-of-state stations may not work each other for contest credit. Contacts made on repeaters do not count for credit.

Florida stations will be divided into two classes. Class-A stations are those operating portable or mobile on emergency power and running 100 Watts or less output inside Florida but outside of their home counties. Class-B stations are *all* other stations operating in Florida. Entrants may be single-operator or multi-operator and this must be indicated on the summary sheet.

Each entrant agrees to be bound by the provisions of the contest announcement, the regulations of the applicable licensing authority, and the decisions of the *Florida Skip* Contest Committee, which are final.

EXCHANGE:

Florida stations send RS(T) and county of operation. Others send RS(T) and US state, Canadian province, or country.

FREQUENCIES:

Phone—3945, 7279, 14279, 21379, 28579, 50.2, 146.52.

CW—3555, 7055, 14055, 21055, 28055.

SCORING:

Florida stations count one point per QSO with out-of-state or other Florida stations. Multiplier is the sum of states (49 max.), provinces (12 max.), and DX countries (27 max.) actually worked; maximum multiplier is 88. Others count 2 points per QSO with each Florida station. Multiplier is the number of different Florida countries worked (67 max.). Final score is the product of QSO points and the multiplier. Class-A stations *only*, multiply score by 1.5 to obtain final total.

AWARDS:

Certificates for phone and CW to the top single operator score in each state, province, DX country, and Florida county. Multi-operator winners will receive certificates as activity justifies. There are also 5 plaques to be awarded as follows: high single operator in Florida and out of state, CW and phone, and the Florida club with the highest aggregate score. A minimum of 25 contacts must be made to be eligible for a certificate.

ENTRIES:

Phone and CW entries are to be *separated!* Along with legible logs in chronological order, a summary sheet is required with each entry. The summary sheet must contain score, number of QSOs, multiplier, station callsign, entry class, number of Florida counties, power source (for Class-A entries), county, state, province, country, or region of operation, callsigns of all operators/loggers if multi-op, name of club if part of a club aggregate score, name and address *typed or printed in block letters*, and a signed declaration that all rules and regulations have been observed. All stations making more than 200 QSOs must also include a dupe sheet. Sample summary and log sheets are available for an SASE from the QTH below.

At the discretion of the contest committee, stations and/or operators may be disqualified for improper reporting, excessive dupes, errors in multiplier lists, unreadable logs, obvious cheating, etc. All entries must be received on or before June 3. Mail all entries to: *Florida Skip* Contest Committee, c/o Florida Amateur Radio Society, PO Box 9673, Jacksonville FL 32208.

MICHIGAN QSO PARTY
1800 GMT May 19 to
0300 GMT May 20
1100 GMT May 20 to
0200 GMT May 21

This year's QSO party will be sponsored by the Oak Park ARC. Phone and CW are combined into one contest. Michigan stations can work Michigan counties for multipliers. A station may be contacted once on each band/mode. Portables/mobiles may be counted as new contacts each time they change counties.

EXCHANGE:

RS(T), QSO number, QTH as state, country, or Michigan county.

FREQUENCIES:

Phone—1815, 3905, 7280, 14280, 21380, 28580.

CW—1810, 3540, 3725, 7035, 7125, 14035, 21035, 21125, 28035, 28125.

VHF—50.125, 145.025, 146.52.

SCORING:

Multipliers are counted only once. Michigan stations score 1 point per phone QSO and multiply by the total number of states, countries, and Michigan counties. Each CW contact counts 2 points; KL7 and KH6 count as states; VE counts as a country. Maximum multiplier is 85.

Others, take QSO points times the total number of Michigan counties. QSO points are 1 point per phone QSO, 2 points per CW QSO, and 5 points for each club-station contact with W8MB. Maximum multiplier is 83.

VHF only entries: same as above except multipliers per VHF band are added together

RESULTS
SARTG WORLDWIDE RTTY CONTEST 1983

Class A—Single Operator		
1.	ON4UN	567,000
2.	UT5RP	307,230

THE LCARA PATCH
NEWSLETTER OF THE MONTH

THE LCARA PATCH is another fine example of the outstanding newsletters being produced every month by ham organizations around the world. Featuring club news and meeting minutes, excerpts from *The Westlink Report* and the *W5YI Report*, DX and FCC news, and much more, the February issue (for example) contained 40 different articles. Congratulations, Editor Gary Knelsley KC8GN!

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

for total multiplier. No repeater contacts are allowed.

AWARDS:

Plaques to Michigan entries with high multi-operator/single-transmittar score, high Michigan score, high Michigan (Upper Peninsula) score, high aggregate club score, high VHF only (100 QSOs minimum), high mobile, and high out of state. Certificates to high score in each county with a minimum of 50 QSOs. Out-of-state certificates for high score in each state and country.

ENTRIES:

A log and summary sheet are requested showing the scoring and other pertinent information, name and address in *block letters*, and a signed declaration that all rules and regulations have been observed. Michigan stations include club name for combined club score. Party contacts do not count toward the Michigan Achievement Award unless one fact about Michigan is communicated. Members of the Michigan Week QSO Party Committee are not eligible for individual awards. Decisions of the Contest Committee are final. Results will be final on July 30th and will be mailed to all entries. Mailing deadline is June 30. Entries should be sent to: Mark Shaw K8ED, 3810 Woodman, Troy MI 48084.

MICHIGAN ACHIEVEMENT AWARD

This will be the 26th year that hams have had their own program to publicize Michigan and its products. Just as for the past years, the governor will award Achievement Certificates to hams who take part in telling the world of Michigan's unlimited resources, opportunities, and advantages. Certificates are awarded on the following bases:

1. A Michigan ham submits log information and names and addresses (if possible) of 15 or more contacts made to out-of-state or DX hams with information regarding Michigan.

2. An out-of-state ham, including Canada, submits log information and names and addresses (if possible) of at least 5 Michigan hams who relate facts to him about Michigan.

3. A foreign ham, excluding any resident of Canada, submits the call letters and name and address plus log information for at least one Michigan ham who has told him about Michigan.

Only QSOs made during Michigan Week, May 19-26, will be considered valid. All applications for certificates must be postmarked by July 1 and mailed to: Governor James Blanchard, Lansing MI 48902.

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

INTO THE ARCHIVES

The other day, while rummaging through the KI2U archives, I came across a facsimile of an ARRL membership application, circa 1914. Did you know that one had to apply for ARRL membership back in the old days? Shows you how standards have dropped. These days, the ARRL even accepts people like me and AF2M.

At any rate, I thought it might be fun to fill in the application and send it back to the League along with my renewal check. Herewith, the ARRL's questions and my responses:

Your name: Ah, an easy question. J. J. Edwards.

Address: Another easy one. PO Box 73, Middle Village NY 11379. My QTH is a little cramped, but the address has a nice ring to it.

Your age: I'm beginning to get touchy about questions like this. Twenty-nine. Really!

Your station call letters: KI2U. Hope they don't mind the number.

Length of your aerial? Which one? Let's see, the boom on my HF beam is about 13 feet long.

Do you obtain your power from batteries or city current? It depends. My HT uses batteries.

Do you use a spark coil or transformer? Strange question. Most of my power supplies have transformers, I think.

What is your approximate receiving range in miles? Hmmm. I didn't get to hear W5LFL, but I have worked EME. Let's say 500,000 miles, give or take a few hundred thousand.

Are you troubled by interference? You bet. My Apple generates a torrent of RFI. Next question.

Have you telephone connection in your house, or convenient? In my house, not my convenient.

Do you keep your station practically constantly in running order? Yes, my station is practically running.

Here's hoping my answers help make a better ARRL.

ELEMENT 1 MULTIPLE CHOICE

1) In a folded dipole:
   1) Current in all conductors are in phase
   2) Current in all conductors are out of phase
   3) Current exists only in the dielectric
   4) Height is rarely important
2) A quarter-wave transformer is:
   1) A quality detector
   2) Also known as a "Q" section
   3) May be used as an inductance transformer
   4) Used only with coaxial feedline
3) A fishbone is a:
   1) Dipole
   2) Traveling-wave antenna
   3) Helical antenna
   4) Type of receiver
4) The antenna used by Marconi to receive the first transatlantic radio signals was held aloft by a:
   1) Balloon
   2) Building
   3) Man
   4) Kite
5) A "capacitance hat" is most often used on:
   1) Cubical quads
   2) Yagis
   3) Dipoles
   4) Whip antennas

ELEMENT 2 TRUE-FALSE

		True	False
1)	All Apple IIs come equipped with a Z80 microprocessor.	___	___
2)	CP/M was the first microcomputer language.	___	___
3)	That fellow in the IBM Personal Computer ads is supposed to be Charlie Chaplin.	___	___
4)	The Z80, Z80A, and Z80H microprocessors are all made by Zilog, Inc.	___	___
5)	The 6502 is made by Intel.	___	___
6)	The floppy disk was invented by IBM.	___	___
7)	VisiCalc is an integrated software package.	___	___
8)	A "mouse" is computer slang for a programming error.	___	___
9)	The term "byte" is a contraction of the words "binary" and "digit."	___	___
10)	FORTRAN is a business-oriented language.	___	___

ELEMENT 3 FILL IN THE BLANK

1) Most solid-state Class C amplifiers are operated with both base and _______ leads connected to ground.
2) S-meter readings are purely _______.
3) "Rushbox" was the name given to a rig with a _______ receiver.
4) Dr. Carl Zenar invented the _______.
5) CMOS: complementary-symmetry, metal-oxide _______.

ELEMENT 4 SCRAMBLED WORDS

Unscramble these words dealing with packet radio.

lanterml	doen	drrehawa
erawtosf	verscetrina	loip
shandhkea	mearf	glipdaerte
coprolto		

THE ANSWERS

Element 1:
1—1, 2—2, 3—2, 4—4, 5—4.

Element 2:

1—False A 6502. Of course, you can always buy a Z80 co-processor board.
2—False CP/M is an operating system, not a language.
3—False IBM says it's not Charlie, but "Everyman." Could have fooled me.
4—True Eight-bit favorites.
5—False By Motorola. A name that's somewhat familiar to hams.
6—True Who else?
7—False It's just a plain, old, electronic spreadsheet.
8—False It's an input device—like a keyboard or joystick.
9—False But "bit" is.
10—False FORTRAN is a language aimed at scientific applications. COBOL is for business.

Element 3:
1—emitter
2—relative
3—superregenerative
4—zener diode
5—silicon

Element 4:
terminal, node, hardware; software, transceiver, poll; handshake, frame, digipeater; protocol.

SCORING

Element 1:
Five points for each correct answer.
Element 2:
Two and one-half points for each correct answer.
Element 3:
Five points for each correct fill-in.
Element 4:
Two points for each word correctly unscrambled.

So, how did you do?

1-20 points—Poor
21-40 points—Fair
41-60 points—Good
61-80 points—Better
81-100+ points—Bingo!

HAM HELP

I am looking for any amateur-radio-related programs for the Timex/Sinclair 1000 computer. I also need a schematic for a Hallicrafters Commander Thirty-Two UHF high-band transceiver.

Scott Harvey KA7FVV
N. 5011 Idaho Rd.
Newman Lake WA 99025

In August, we are spending our third holiday in your wonderful country. As we have done before, we are requesting a couple of nights of hospitality in New York. This is our first visit to the city, but we have made good friends in Washington and LA through this unorthodox method. Hospitality will of course be reciprocated in our home, which is convenient for Scotland and Hadrian's Wall and on a direct route to London.

We are in our late thirties and very easy to get on with. We happen to prefer meeting people informally to staying in impersonal hotels.

Michael is a licensed ham, a computer engineer, and a soaring instructor. I am a final-year student doing social work. We love cats and have no feeding problems or peculiarities. In fact, we are a thoroughly nice couple. All letters will be replied to.

NEVER SAY DIE
editorial by Wayne Green

from page 6

have to have some system for getting Novices to keep on moving their code speed up until it reaches at least 35 per. It means making sure that we don't let a few lazy hams reflect badly on all of us by letting their code speed slip just because they spend most of their hamming time rag-chewing on phone or working RTTY. None of us wants to see that happen, right?

One possible way to help all of us keep our code speed up, even if we do spend a good deal of time on phone, might be to require all operators to exchange callsigns only on CW, even for phone contacts. After all, RTTY operators for many years had to send their calls on CW before and after each transmission. We could go further and make it illegal to give your call on voice. I'd like to see someone put that into a petition and send it to the FCC as part of the obviously needed beefing-up of code.

You know, if we don't outlaw repeating the callsign on voice, we could see many ops putting the CW identification on a ROM chip at 100 wpm, operated by the mike button. Could we even outlaw the use of computers to decipher the callsigns sent on CW? Why not?

The more we encourage amateurs to use computers and code keyboards, the more likely we are to have amateurs getting lazy about their code speed. Also, if any of the FEMA or CD crowd get a taste of high-speed digital communications, we're going to have a hard time getting them to let us use Morse code for emergencies. Best we do what we can to discourage RTTY, ASCII, packet radio, and other systems which do not depend entirely on the code skills of licensed amateurs. We sure don't want any unlicensed operators putting us out of work in emergencies—not even after WTCAD.

Computers and keyboards are pernicious things, automating communications and taking it out of the hands of us, er, amateurs. The ARRL has been fighting RTTY for the last thirty years—obviously going along with the main line of amateur convictions.

Okay, what should we do next? I've already proposed a little rule change to the FCC which I feel is necessary if we are going to make sure that none of the old-timer hams lets his code speed slip. Perhaps the next step is to get a bit more spectrum for CW communications. Wouldn't it be great if we could put the 40m band back the way it was 50 years ago? That used to be strictly a CW band in those days. And you didn't hear any foreign broadcast stations there, either. It wasn't until we opened 40m to phone communications that they were able to creep in. Now they've just about squeezed amateurs out of our phone band. If we go back to CW, we might be able to push those bums out. So let's see some proposed 40m changes, eh? Let's get phone out of there—and perhaps RTTY also.

40m used to be the truly great ham band of the world. There used to be more ham activity—and that was 100% good old honest CW, chum—than on any other ham band. It was packed solid with CW ops 50 years ago—and can be again. Ask any old-timer about it.

You know, I think 40m began to go downhill a bit when they invented the vfo. You youngsters don't know the excitement of plugging in a crystal, firing up your rig, calling a long CQ, and then tuning the entire 300 kHz of the band for a call. None of this slam-bam stuff. None of these three-by-three calls. If you wanted to get someone, you called CQ for three to five minutes. And when you were calling someone, you called them for several minutes so they could tune up the band and find you, often checking hundreds of signals as they tuned. Doesn't that sound worlds better than sending a quick CQ and checking your frequency? You bet! Do you think we could bring back crystals and junk all these confounded synthesizers we've been forced to buy?

If they took all that crap out of our rigs, they could get the price down more where it ought to be. I remember when you could buy a nice ham receiver for $29.50—the good old Hallicrafters Sky Buddy. By the time they've put in ten or fifteen bands, synthesis, sideband generators, and demodulators, is it any wonder some of these rigs cost over $500? We don't need all that stuff for CW, so let's get rid of it.

Hey, I'll be looking for you on 40m just as soon as I find where I put my key, okay? It's around here somewhere—I saw it a couple of years ago.

NEW PRODUCTS

EXL-5000 DIGITAL COMMUNICATIONS TERMINAL

Amateur-Wholesale Electronics has introduced the revolutionary EXL-5000 digital communications terminal.

The EXL-5000 features a built-in high-resolution long-persistence green monitor for sharp, clear images with no jiggle or jitter even under fluorescent lighting. Also featured are an external plug-in keyboard and a versatile built-in power supply for 117/234 V ac or 13.8 V dc. Operation is by front-panel push-button controls.

The EXL-5000 includes capability for operating in the new AMTOR modes A, B, and L. A high-speed demodulator allows Baudot and ASCII operation from 12 to 600 baud at TTL level, in increments of 0.1 baud. The demodulator will work with high or low tones. For transmitting, AFSK or FSK keying can be used. Morse sending and receiving speed is adjustable from 5 to 100 wpm in 1-wpm steps, with receive auto-tracking and variable transmitting weight.

A 1,280-character display memory is split into two pages of 40 characters by 16 lines. Seven independently-programmable 72-character channels and eight independently-programmable 24-character channels allow storage of messages for permanent use. The memories can be preloaded and reprogrammed. Errors are easily corrected. The programmable memories are backed up by an internal battery so that they are never lost.

Other features of the EXL-5000 include: full control, function display, split-screen operation, automatic send/receive switching, automatic carriage return and line feed, automatic letters-code insertion, word-mode and line-mode operation, word wraparound, simultaneous send-receive capability, selective calling, automatic timer-controlled transmission, RY and "quick-brown-fox" test signals, automatic ID, random-character generator for code practice, a printer interface, provision for an external monitor, a built-in audio monitor, a bar-graph LED tuning meter, noise-reduction receiving circuit, time clock, and much more.

Further information about the EXL-5000 may be obtained from *Amateur-Wholesale Electronics, Inc., 8817 S.W. 129th Terrace, Miami FL 33176; (305)-233-3631.* Reader Service number 479.

MODEL 510SA SMART PATCH

A new simplex autopatch will work on any amateur or commercial simplex radio and is easy to install. CES engineers have redesigned the VOX-enhancement circuitry and mobile-presence detectors in the Model 510SA Smart Patch. The improvements allow the advanced microcomputer in the Smart Patch to keep the user from missing words or information. The Smart Patch gives the mobile complete and immediate full break-in capability without losing information. The immediate control feature allows operation in the amateur service because Smart Patch cannot transmit on top of another mobile. Transmission can be terminated by an operator simply keying his transmitter. Installation consists of connecting RX audio, TX audio, PTT, and power. For more information about the Smart Patch, contact *Communications Electronics Specialties, Inc., PO Box 2930, Winter Park FL 32790; (800)-327-9956.* Reader Service number 477.

NEW HT AMPLIFIERS

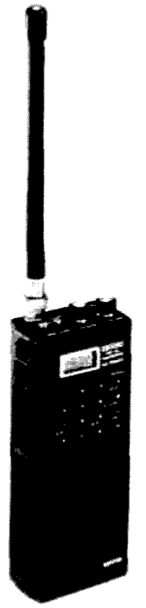
Mirage Communications has recently announced the addition of two new low-profile HT amplifiers to their expanding line of American-made communications equipment.

The B23A (144–148 MHz) and C22A (220–225 MHz) incorporate features that typically are only available on larger, more expensive amplifiers into a slim-line, low-profile package for HT use. Both amplifiers feature a built-in receive preamp that delivers a 1.5–20-dB noise figure, all-mode operation (CW, FM, or SSB), and automatic antenna changeover.

The rf power input range, from 100 mW to 5 Watts, and high rf power output (B23A, 2 W in/20 W out; C22A, 2 W in/30 W out) make them ideal for use with low-power transmitters.

The B23A and C22A are backed by a 5-year factory warranty (1 year on rf power transistors) and a worldwide sales network.

For more information, contact your nearest dealer or write to Everett L. Gracey, *Mirage Communications, PO Box 1000, Morgan Hill CA 95037; (408)-799-7363.*



The Icom IC-02AT hand-held.

IC-02A(T) HAND-HELD

Icom has announced the IC-02A and the IC-02AT two-meter hand-helds. These compact multi-featured hand-helds are the same size as the IC-2A series but have features found on no other amateur hand-held.

The IC-02A and IC-02AT are designed to be compatible with all existing IC-2A accessories plus some new accessories. An important feature of the IC-02A series is that it has 32 PL tones built into the unit as standard. These tones are programmable from the front-panel pad and may be used with any frequency at any time.

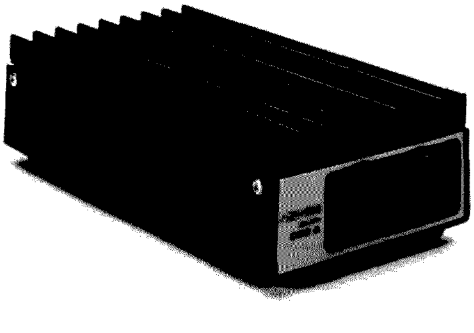
Any frequency on 5-kHz spacing in the two-meter ham band may be called up in the IC-02A. All frequency entries as well as control functions for memory, scanning, etc., are selected by the 16-button pad on the face of the radio. Included are priority watch, scanning of both memories and programmable band scan, and DTMF on the IC-02AT model. The unit features 10 memories which store frequency, PL tone, offset and offset direction, and an internal lithium battery backup. The priority channel is a unique feature to the IC-02A and IC-02AT, as well as the custom LCD readout with an S-meter function.

The IC-02A series will run at 3 Watts with the standard BP3 battery pack, or at 5 Watts with an optional high-power battery pack. A long-life battery, 8.4 volts at 800 mA, will be available to double the working time of the standard 3-Watt-output unit. Batteries may be charged a variety of ways.

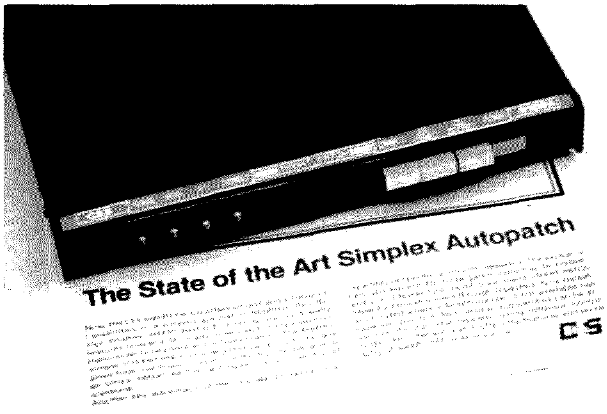
The IC-02A series has an environmentally-sealed case with O-ring seals to protect it against dirt and moisture. A heavy-duty aluminum back provides heat sinking for the 5 Watts of power.

A power connector is supplied on the top of the unit. Twelve volts applied there will power the unit as well as charge the battery pack.

For further information, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue WA 98004; (206)-454-8155.*



Low-profile HT amplifier from Mirage.



The Model 510SA Smart Patch from CES.

NEW HEADSET

Telex has introduced a lightweight headset for hand-held land-mobile transceivers. The ProCom 352-IC weighs 2.6 ounces when worn with the headband. However, when the snap-on headband is removed, the headset weighs one ounce and can be clipped directly onto eye- or sunglass frames.

When using the headset, the radio remains on the operator's belt. There is no longer any need to hand-hold the radio for communications. The headset is equipped with an in-line push-to-talk switch which also clips to a belt.

A soft ear tip channels incoming messages directly to the operator's ear so communications are essentially private. The noise-cancelling electret microphone is designed for very close talking and transmits the operator's voice clearly even in high-noise environments. The electret mike is also immune to electromagnetic or radio-frequency interference so it can be operated effectively near power lines, large transformers, generators, broadcast towers, and other equipment which so often interferes with radio communications.

The headset plugs directly into Icom or Ten-Tec hand-held transceivers. The unit is available now at local two-way radio dealers. For more information, contact Norman Hansen at *Telex Communications, Inc., 9600 Aldrich Ave. S., Minneapolis MN 55420.*

BUCCANEER SEALED ELECTRICAL CONNECTORS

A new line of English-made sealed connectors for use in hostile environments, named Buccaneer, has been announced by Radiokit, the US agent. The connectors, which are made in bulkhead, chassis, and in-line styles, are available in 2-, 3-, 6-, and 7-pin configurations as well as 50- or 75-Ohm BNC (coaxial) types for HF and VHF radio. They are waterproof, dust-

proof, rugged, and reasonably priced. The use of screw terminals or crimp connections provides ease of wiring end results in e surprisingly-small-size unit.

Originally designed for marine applications where the connecting and disconnecting of power and signal equipment is desired (i.e., search lights, generators, radios, radars, sonars, masthead antennas, etc.), these connectors can be used in most applications where reliability is essential. Other suggested uses are in dusty or damp locations and places where a connection is subject to physical abuse.

The units are made from a high-density fiberglass-filled nylon. At the cable-entry end, waterproof grommets may be changed for different cable diameters. The mating seal is achieved by a compressed O-ring. Each connector has its own captive screw-down weatherproof cap which also serves as a tool for assembly and disassembly of the connector. The 3-pin version is rated 10 A at 250 V.

For further information, contact *Radiokit, Box 411, Greenville NH 03048; (603)-878-1033.* Dealer inquiries invited. Reader Service number 476.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

I left a few items hanging last month; this month I will see if I can tidy up those few things. First off, we had looked at the problem of running a Murray-encoded teleprinter off of a computer's ASCII output.

If only it were the other way, things with a hardware solution (as we indicated would be looked at) would be a lot easier. Transforming Murray to ASCII involves a rather simple hookup (which can be accomplished with a PROM or two, a UART or two, and a few support chips), but converting the other way is quite a bit more complex. One reason for this is the problem of case-shifting in Murray. Although the ASCII machine may put out a simple string, say a callsign, as "W-A-3-A-J-R" straightaway, sending the same string in Murray involves the shift characters, sending "W-A-FIGS-3-LTRS-A-J-R." These must be inserted in the proper place with the stream of data coming downline.

Another major problem is the speed of transmission. As we discussed last month, most ASCII transmissions are running a good deal faster than Murray, and if you allow for the necessity of inserting occasional LTRS and FIGS characters, the effective data rate becomes even slower.

With this in mind, take a look at Fig. 1. This circuit was originally published here in *73* in September, 1977, in an article written by J. Gary Mills VE4CM. Although the design may resemble a work of modern art to the novice, it really is quite straightforward and one of the best of the lot that I have seen. Serial ASCII is accepted by the 1013 UART at the left, and the parallel output is decoded by a specially programmed PROM into the Murray equivalent. The data stored in the ROM includes a bit to indicate the case of the character, and tests are performed on the data stream to insert the proper case shift where indicated.

A clock circuit, shown in Fig. 2, is used to drive the Murray output at any popular speed from 60 wpm to 100 wpm (45.45 baud to 75 baud). The speed of the ASCII portion of the circuit is fixed at 110 baud, commonly called 100 wpm. Please don't confuse 100 wpm Murray (75 baud) with 100 wpm ASCII (110 baud). It has to do with the greater number of data bits (11 in ASCII, 7.46 in Murray) and the need to send them faster to get the same number of characters out. If you still don't follow, reread last month's column, calculator in hand.

In order to interface this circuit with a teleprinter, the scheme presented in Fig. 3 may be useful. This will serve to connect this, or any other TTL-level output, to drive a Model 33 or Model 35 Teletype® machine. I think it may come in handy for many an application.

What about that PROM, you say? Well, the author of the original article presented an abbreviated coding table for the code conversion. Presented here as Fig. 4, it is, I agree, a bit sketchy. You can get the idea, however, and the complete diagram may still be available from the author of the article or VE4 Logic, 76 St. Clair Blvd., Winnipeg, Manitoba, Canada R2C 0V2.

The second line I left dangling was a new RTTY program written by Clay Abrams K6AEP. Well, Clay has done it again! NEWRTYCW is a program written for a TRS-80C Color Computer with 16K or more memory which does not require Extended Basic or a disk to run (more on that last point later). It enables the CoCo to send and receive Murray RTTY, ASCII RTTY, and Morse CW at essentially any speed.

This machine-language program is supplied on a cassette tape which CLOADMs and executes automatically. This makes it impossible to load and look at or duplicate with the SAVEM command. After booting, the program asks for your callsign or other ID, up to 31 characters which can be sent at a keystroke.

The program itself is rather striking in all its abilities. There are four small "station" buffers, 254-byte buffers which are useful for storing three or four lines of text. Also available is a keyboard buffer,

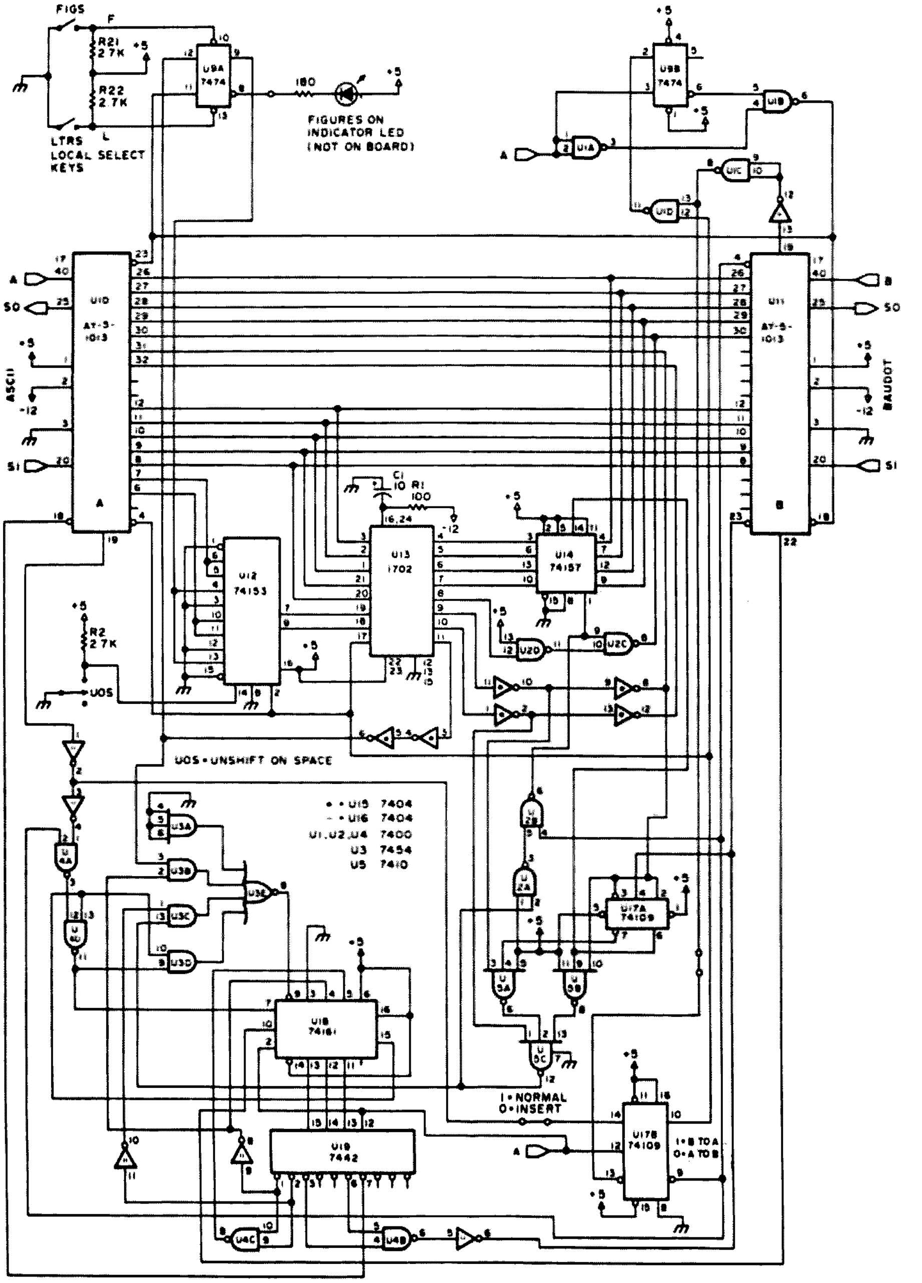


Fig. 1. ASCII-to-Murray converter.

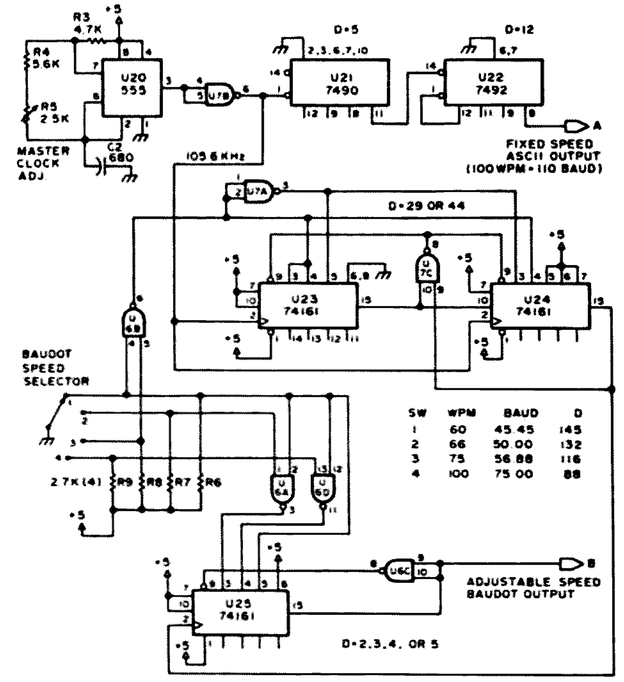

Fig. 2. Clock driver circuit.

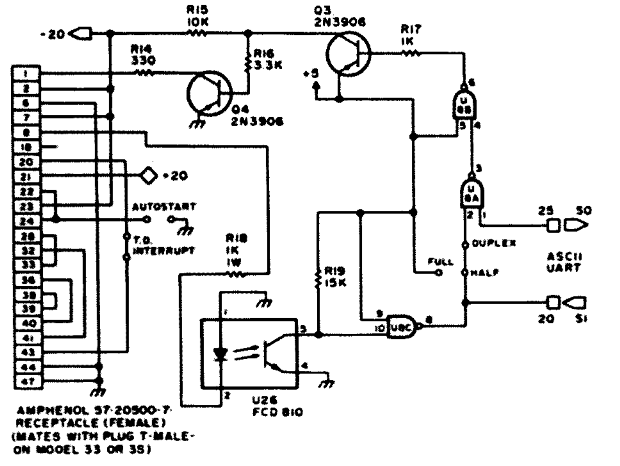

Fig. 3. Teleprinter interface.

12K in size on a 32K machine, and a receive buffer of equal size. These buffers may be loaded from tape, saved to tape, or printed out on the system printer. There is also a raft of features. Let's look at a few of them.

On RTTY, an automatic CR/LF pair may be generated, if desired, after the character in the tenth through eightieth column. At which position to limit, if at all, is easily specified. Station buffers, keyboard buffer, or even the receive buffer may be transmitted with a keystroke. Unshift on space is supported and may be turned off if desired. The number of carriage returns sent may be changed from the default of one up to nine. This is useful on some circuits, such as MARS, where I well remember the required CR-CR-LF-LTS-LTS sequence. There is even an automatic RY generator!

When operating CW, the functions are essentially the same as with RTTY, with a few exceptions. The speed of the incoming station is tracked, with transmit speed being set ahead of time. All the buffers work the same, as do the features, except that the RY test does not send Morse Vs. However, there is a code-practice option which sends random five-character groups with the audio heard over the TV set speaker. By the way, the CW portion provides several keys for "specialized" signals: the @ key is the BT (— . . . —), $ is the AR (. — . — .), the * is the AS (. — . . .), and several others.

Now, there are a few problems with this program. Sorry, Clay, but I do have my opinion! First of all, this is a self-booting tape. While I have no need to copy it, I would like to transfer it to disk, at least to load it. That cannot be done, as it assumes control of the machine as soon as it loads.

Secondly, saves and loads can only, currently, be made with tape. Clay does indicate, however, that a disk version is in the works.

And finally, if you have the CW transmit speed set, say, at 15 wpm and tune in a station sending at five, your response will stay at the faster speed unless you break out of the receive routine and reset the speed. Kind of messy. Two possible solutions would be to have the sending speed approximate the receiving speed (optionally, of course) or to have a control function reset the speed while still receiving.

One more thing—the keyboard input seems a little sluggish on my CoCo2. When Tandy upgraded the Basic ROMs, they moved the routine that polls the keyboard for input by a few bytes. If this program is using the old address, that would explain the sluggishness. I can't check it because of the "locked" nature of the program.

The solution is to use extended indirect addressing instead of plain extended addressing. It only takes one byte of data, but it would mean reassembling the whole program. Oh well, something more to think about!

All in all, this program looks hard to beat. Clay says that he is selling them like hotcakes. I am sure he would like to hear from you. Drop him a note care of Clay Abrams Software, 1758 Comstock Lane, San Jose CA 95124, and tell him WA3AJR sent you!

Now, a lot of you have been writing me notes and asking for a repeat of some of the basics. I don't think that reruns here are in order, but I will agree that there are many newcomers out there who might benefit from a review of material printed here several years ago. Therefore, I cautiously announce a new service. I shall try to put together on a monthly basis a compendium of RTTY material to be available by mail from the above address. The first edition will be an elementary introduction to RTTY, with other topics to follow in future months. Such items as RTTY reception, transmission, and machines are some of the items I hope to review. I shall announce each edition here as it becomes available.

To receive your copy, just send $2.00 and a self-addressed, stamped envelope (or sufficient US funds for foreign postage) to me at the above address. I hope this answers the needs expressed in so many of your letters. Watch this column for announcements of future editions.

Next month begins our eighth year of RTTY Loops. It is sure to be exciting, so be sure your subscription to *73* is current and watch for each month's RTTY Loop.

THE WONDROUS WWV—PART 2

Have you been listening to WWV at 18 minutes after the hour as I suggested last month? If not, turn on your receiver, tune in WWV at 10000.000 kHz, and listen as you read this.

In addition to its main function of providing a time and frequency standard, WWV also disseminates information for other government agencies. Included are storm warnings at 8–10 minutes after the hour and Omega navigation information at 16 minutes after (the Omega system is a VLF location system—10–14 kHz). The information of greatest interest to amateur-radio operators, especially DXers, is the Geoalart bulletins, at 18 minutes after each hour.

The information in these bulletins is produced by the National Oceanic and Atmospheric Administration (NOAA), which shares space in the same building as the National Bureau of Standards' master cesium-beam clock (see this column, last month.)

Every three hours an officer at the NOAA Space Environment Services Center in Boulder picks up a phone and calls a special drum recorder in the master clock room at the WWV transmitter site, 35 miles to the north in Fort Collins, Colorado. That drum is controlled in the same way as the drum which has the voice time announcements. When the 18th minute rolls around, the recording is broadcast on WWV. (You can also listen to the message by calling (303)-499-8129.)

The form of the message doesn't vary. First comes the solar-flux level from Ottawa, Canada. This is followed by the A index, the K index, and information on solar activity and geomagnetic storms. DXers can compile this information and use it to increase their DX efficiency, especially in times of low sunspots, such as now. Let's look at this information and see how it relates to DXing.

The Solar Flux

The first item covered in the Geoalert bulletin is the solar flux. This is the amount of radiation coming from the sun at 2800 MHz, as measured in Ottawa. (Ottawa figures are used because they have been recorded since 1947 and they provide a consistent picture of the sun.) This solar-flux figure is directly related to the number of sunspots on the surface of the sun facing the Earth. It is easier and more consistent to measure the solar flux than to go through the somewhat arbitrary calculations of sunspot numbers. And solar flux can be measured when it's cloudy!

The solar-flux index ranges from 66 to about 250 or even higher. A reading of 68 is equivalent to zero sunspots—zilch! At about 80, there is enough radiation coming from the sun to open the 15- and 10-meter bands to some parts of the world. Higher readings suggest a better ionosphere, from the ham-radio point of view. What is most important about the solar flux, however, is the *trend* of the figures. A rising flux suggests improving band conditions; falling figures indicate the bands are deteriorating.

Also, the flux figures provide some predictive value for the next month. Since the solar flux is tied directly to sunspot activity and because the spots swing around as the sun rotates about once every 27 days, you can make some guesses about radio conditions 27 days ahead, based on today's figures. Alas, the sun is more fickle than this suggests. Even the largest spots have been known to completely disappear as they go around the back of the sun. And new spots spring up without warning. Still, the value of the flux 27 days ago is one of our best predictors of band conditions. Just don't bet your life on it.

Another useful predictor based on the solar flux is a sudden increase in its value. The extra radiation suggests that more particles will be streaming from the sun, and it's these ions, electrons, etc., which stir up the ionosphere and give us good DXing. These particles move at speeds less than that of light, so they arrive a day or two after the flux values change. So a sudden increase in solar flux suggests better band conditions in the next day or so.

To make the best use of the flux figures, you should write them in your log daily. Then compare radio propagation at *your QTH*, with *your* equipment, to the flux values. With time, you will begin to see how that solar flux correlates to DXing from your station. DX clubs often have a member who keeps track of the flux values on a daily basis and shares the data over a repeater. And some of the DX bulletins publish this information. But entering this figure daily in your own log is still the best way to track band openings. Try to get the figure soon after the 1800Z daily update.

The Other Figures

While solar-flux level is a good predictor of future band conditions, the A and K indices provide a better idea of what is happening *now* on the bands. The A index is a figure between 0 and about 100 (although readings as high as 400 have been recorded). It is a measure of the geomagnetic activity of the Earth's magnetic field. When the A index is low, not much is happening, and signals pass with little attenuation or loss. An index reading of 10 or less suggests "quiet" conditions, just what the DXer ordered. As the sun starts acting up, however, the A index will rise, the Earth's magnetic field starts jumping around, and absorption increases. Your signals get weaker. At high absorption levels, you might as well turn off the radio and go mow the lawn or get reacquainted with your family.

Unfortunately, the A index is yesterday's news. Even though it is updated every three hours, it reflects what went on in the ionosphere yesterday. So when you hear a high value on the A index, you know that the bands stunk yesterday, something you were probably already aware of. This is similar to getting weather "forecasts" for the previous day.

So why pay any attention to the A index? First, the *trend* of the index is important. If the absorption level is rising, the bands will be getting worse. If it's falling, maybe you should anticipate spending more time on the air. Also, as with solar flux, the A index tends to repeat at 27-day intervals, as the sun rotates. A bad day (high A value) 27 days ago suggests today will be punko, too. Of course, the vagaries of the sun and a little Murphy keep this from becoming as simple as it seems.

The A index is especially meaningful as related to polar radio propagation and high-latitude east-west paths. The north-south paths are little affected even on days of high A readings. So consider swinging the beam to the south on days of high absorption.

The last figure given in the 18-minutes-after-the-hour Geoalerts is the K index. This is similar to the A index, except that it is much more current. It is actually measured right at the Boulder, Colorado, labs and updated every three hours like the A index. The K index varies from 0 to 5, with the higher numbers reflecting higher absorption, just as with the A index. A K reading of 4 or 5 suggests lawn mowing. A low K of 0 or 1 means it might be well worth tuning around the bands.

Again, the *trend* of the index is as important as the actual value. If the K index is higher than it was three hours ago, things are getting worse. Tell your spouse you'll go out to dinner after all. Decreasing K readings mean the absorption is lessening.

To recap these numbers, DXers pray for high solar flux and low A and K readings. A solar flux of 200, A=3, and K=0 would be a banner day to DXers. A flux of 85, A=34, and K=4 encourages even the most avid DXer to consider stamp collecting.

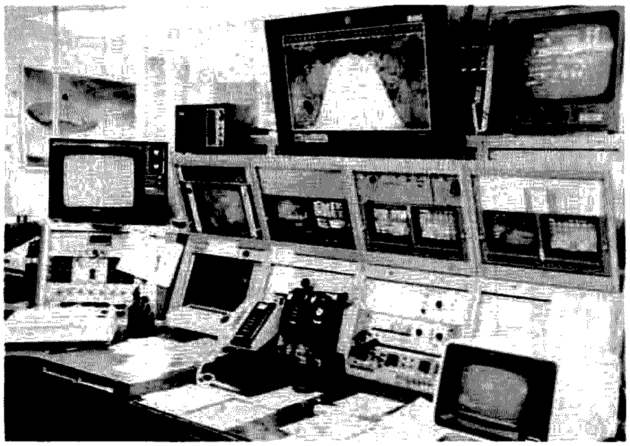

Photo A. The control room at the Space Environment Services Center in Boulder, Colorado. Information on the state of the sun and the Earth's magnetic field pours into this communications hub and is distilled into the WWV bulletins at 18 minutes after the hour.

Storm Warnings

The last item on the Geoalerts is a description of solar activity, especially any solar flares. Flares are sudden eruptions on the surface of the sun which fling out enormous numbers of charged particles into space. Flares occur very suddenly, lasting a few minutes to a few hours.

Flares can be real disasters for DXers. The swarms of particles and ions rip up our ionosphere, sending absorption sky high (if you'll pardon the pun). A major flare can produce a Sudden Ionospheric Disturbance (SID). Most hams have experienced one or more of these: You turn on your rig and you hear nothing, absolutely nothing—not on any band. I once spent two hours ripping apart my station and tearing into my receiver, certain that something was seriously wrong. Of course, something *was* wrong, but with the ionosphere, not my station. It was several hours before the bands began slowly to return to normal.

There is nothing you can do about the SIDs. When one hits, turn off the radio and walk away. Unfortunately, we'll be seeing a lot more of these DX disasters in the next few years. With declining sunspot activity, SIDs tend to become more common. Also, there seems to be a vague 22-year cycle associated with SIDs, and the 1984–1985 range is 22 years after some of the most severe SIDs ever recorded.

Fortunately, WWV will give you some advance warning about SIDs. The Space Environment Services Center (SESC) monitors the X-ray output of the sun constantly. Information on the X-ray level pours into the Boulder labs from stations all over the globe and from two satellites above the Earth, GOES 5 and 6. This information reflects activity on the sun as currently as possible, with only an 8-minute delay for the speed of light.

The information on the X-ray flux is automatically charted on a video monitor (see Photo C) as one part of the SESC control desk (see Photo A). The office is manned 24 hours a day, with staff such as Master Sergeant Harry Sorg (see Photo B) keeping a close eye on any sudden changes in the value. The close-up photo of the video screen shows a Class M flare, serious enough to disrupt communications. A Class X flare wipes out everything, and a very powerful Class X flare can knock out power lines and do other physical damage. High-flying airliners on polar routes might be exposed to excessive radiation during flares. And persons living in high-latitude regions will be treated to a glorious aurora, which they might as well watch, since all radio propagation will be nonexistent!

But thanks to the time lag between when the flare starts (as indicated by the sudden burst of X-rays) and the time the particles which do the damage arrive (a day or so later), SESC can issue warnings to help reduce damage. And vital communications lines can be prepared for the coming radio blackout. When a major flare starts, Sergeant Sorg and his counterparts start notifying a list of customers that the particles are on the way. And they also put the information into the geophysical alerts at the end of the 18-minutes-after-the-hour WWV bulletins.

The SESC tries to predict flare activity based on complex models and studies of the sun. The magnetic fields around the sunspots, the relative motion of the spots, the flare history of a spot group, and other information is compiled and analyzed at the SESC office to generate this forecast of flare activity.

So when you hear the words "Solar ac-

Photo B. Master Sergeant Harry Sorg points to the solar flare recorded on the video screen. X-ray data from ground stations and satellites reveals the current state of solar activity.

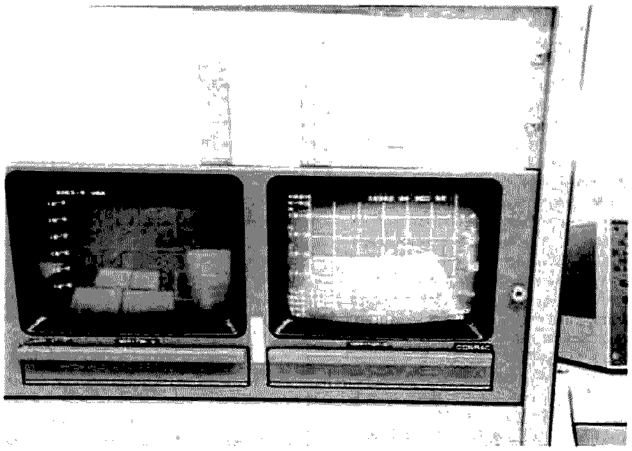

Photo C. Close-up of the X-ray monitor screen showing a Class M solar flare at about 1545Z. In a day or two, radio propagation will be affected by the charged particles from this flare.

tivity expected to be high" on the WWV bulletin, be prepared for some fireworks. On the other hand, the influx of solar radiation which arrives at the speed of light tends to increase the ionization of the atmosphere and *improve* radio propagation for a few hours. So a solar flare is a mixed blessing for DXers. The first few hours will be good radio operating times. In fact, some of the best possible propagation occurs just after the onset of a flare. But then the next day or so when the particles arrive: wipeout!

All of this information is packed into a few words, sandwiched between the tones, ticks, and beeps of the regular WWV information. And I haven't even mentioned some of the other data available from the WWV broadcasts, such as musical tones, standard audio frequencies, information on how fast the Earth is turning (listen for the ticks after the start of each minute!), and more.

The National Bureau of Standards and WWV provide a unique and useful service to amateur-radio operators and others throughout the world at remarkably low cost to the taxpayer. Keep them in mind the next time someone starts talking about government waste and inefficiency. And I would like to especially thank those NBS staffers and others who made my visit to the wondrous WWV and the Department of Commerce Boulder labs so informative and enjoyable: John Milton, Chief Engineer of WWV, Howard Machlan, WWV Engineer, Master Sergeant Harry Sorg, SESC staff, and especially Fred McGehan, Public Information Officer for the NBS.

That's it for this month. Next month we'll get down to some nitty-gritty about propagation and how you can use all of this information to improve your DX success. Meanwhile, listen to WWV at 18 minutes after the hour, tune into 14100, and log what you hear on that frequency. You'll be surprised at what you hear! I'll cover more on the Northern California DX Foundation beacon network in a future column. Good DX!

REVIEW

N2NY HAM MASTERTAPES

Well, I knew it would finally happen. These days just about anything you can imagine is showing up on videocassette. Movies, Broadway shows, hard-core porn, musicals, and training/instruction on just about everything from A as in apple growing to Z as in the training of zebras. It's all there for you to enjoy if you happen to own a home videocassette recorder and are willing to pay the price for the software.

Inevitably, the time would come when some enterprising ham would think in terms of training prospective amateurs using this developing media. Last spring, while visiting the east coast during the pre-production planning for "Amateur Radio's Newest Frontier," I was invited by Larry Horne N2NY to be a guest on his cable-TV program. It was then I learned that Larry had spent the better part of the past 24 months planning the production of an all-inclusive videotaped amateur-radio training program.

Training newcomers is nothing new to N2NY. He's been teaching amateur radio literally from the day he was first licensed, 32 years ago. His first graduates were his fellow grade-school students, and N2NY has been going strong ever since. His dream has always been that of making entry into the ranks of the US Amateur Service available to anyone who has the interest.

The release of the Ham MasterTapes training course by N2NY did pose one problem for publications such as this. Simply, neither *73* nor any other amateur-radio periodical had been put in the position of having to review a videotape. *73* was a bit luckier than the rest. They knew that one of their Associate Editors makes his living by "making television," and that's how it came to pass that this writer finds himself producing a review on the N2NY Ham MasterTapes.

The main question is whether or not the N2NY Ham MasterTapes are worth the $200 price tag. From my standpoint, the answer is in the affirmative, but in the end only you can make that judgment. Dollarwise, they are an excellent investment for anyone planning to teach an amateur-radio school of any sort because they take away the need of having to solicit specialized equipment usually required for live demonstrations. It also does away with those embarrassing moments when a demonstration either fails or backfires in a way that nobody is expecting. A VHS or Beta home VCR and a color TV set replace the collection of gear that is usually necessary for such classes, and the demonstrations work perfectly every time.

I'm convinced that in his younger days, Larry was as addicted as I was to the NBC children's science program, "Watch Mr. Wizard." In his Ham MasterTapes, N2NY has utilized and expanded upon the teletraining methods developed—and still used by—television's teaching master, Don Herbert, the real Mr. Wizard. Those of you who were around during Mr. Wizard's tenure on NBC will remember that each week Don would spend 30 minutes every Saturday afternoon teaching one of the local kids what he called "the magic of science in everyday living." True, the local kid was a professional actor or actress, but the idea was that of educating by making learning fun. That's exactly the method utilized by Larry Horne in Ham MasterTapes.

Larry appears as much at home before a TV camera as he would be if you met him on the street. The fact is that this is actually the case. After several years of producing and hosting a weekly program, he has developed a very laid-back style of his own. This style, along with his obvious dedication to what he is doing, ranks him quite high on the list of educational television instructors. His on-camera presence helps counter the somewhat plastic performances of the others, which is about the only flaw in the entire production.

There are two methods of producing any film or videotape. One is Rehearse - Run-Thru - Rehearse/Tape - Air/Tape; the other is Block and Shoot. Larry's decision was to use the latter, and it appears to have been a wise move. It meant that an entire script did not need necessarily to be memorized at one time, and it permitted the use of prompting devices as well.

By using Block and Shoot, attention could be given to each individual aspect of the overall presentation, permitting attention to be paid to minute detail, simple things, such as the way an array of handheld radios was placed on the table before the trio so that they were clearly visible on camera. Without several additional people to keep exact notes, it is all but impossible to use the earlier method without matching shots using an additional VCR playback for the purpose. By going to Block and Shoot, each scene could be done individually as many times as needed until Larry, as producer, was satisfied. The actual taping took five 10-hour work days. Again, by way of comparison, your TV sitcom usually takes only 4 hours total to tape, but at least 7 days...sometimes 20-hour days of preparation and rehearsal.

These days, it appears that a TV program is made or broken in post-production. That's another word for editing, and it's become an exacting science. Under Larry's personal supervision, the program was edited by his director, Christopher Stola, and the post-production phase is one of the high points. I say this based upon the minimal use of far-out special effects that might tend to confuse the viewer. Larry and Chris used the KISS Principle (keep it simple, stupid) with scene-to-scene transitions being the traditional "fade," and all transitions in a given segment being either straight cuts or cut-to-freeze-frame when a point needed emphasis.

In one place, Larry did get a bit liberal with his use of the freeze-frame, but it was something truly spectacular. Ever discharge a capacitor and notice a spark? Moves by pretty fast, doesn't it? Not in the Ham MasterTapes. Using stop-motion freeze, the viewer is treated to a spectacular fireworks-like display as the capacitor is discharged in a fiery fury. Almost something akin to the effects in "Star Wars," but not planned to be that way.

Every important point covered is emphasized by on-screen "fonts," i.e., texts superimposed on the screen, such as the name of a reporter on a news program. Larry uses fonts liberally as a way of permitting the viewer to take simple notes during the segments and review each subject after each of the 26 segments has been completed.

Just about everything you can think of (and some items you may not expect) are contained in the N2NY Ham MasterTapes. Larry does not stop at giving the minimum amount of information needed to pass an amateur examination. This is where most training courses end, leaving the student hung out to dry with a license and radio, but no experience with either. The traditions of amateur radio are rarely, if ever, included in programmed training courses. The so-called cheat books give only questions and answers. Most courses simply teach the minimum necessary to pass a

test. The N2NY Ham MasterTapes pick up where everyone else leaves off.

Larry has told this author quite candidly that learning how to operate various modes and rigs is important, but so are proper on-the-air procedures. There are also the traditions of the Amateur Radio Service, and they are included in the study course—things like the best way to conduct oneself on the air, entering a QSO, and operating a repeater. Even the way in which repeaters are coordinated to their channels by voluntary coordination councils is explained, and in detail. To put it concisely, everything other than CW is included in the N2NY Ham MasterTapes training program, and that puts it head and shoulders above just about anything else on the market.

As you sit and watch the Ham MasterTapes series, one thing comes across. The people who put them together really cared about what they were doing. Quality of production was obviously paramount to Larry and his crew, with cost of production taking a back seat. There would be very little I would change if it had been my show, except perhaps to use professional actors in place of volunteer students. While this may seem to be a contradiction in terms, as any good producer or director will tell you, the people who handle themselves best and appear natural on camera are those who have been specifically trained for that task. Each of us does one job best, and when actors are called for, I believe in using them. There's no substitute for experience.

I won't tell you the best way in which to use them, but whether you purchase the tapes for your personal use or to augment a training class run by your club, they are definitely a worthwhile investment. They have the ability to stand alone or be incorporated into a structured training program—and that's another part of their beauty. Any time a technical subject is broached and where needed demonstrations are included, Larry takes the time to stop and explain what he means in simple, easy-to-understand layman's terms. One thing is sure: Your students won't get bored.

The tapes are available on VHS and Beta formats at standard play speeds (Beta II and VHS-SP) so as to be compatible with just about any home VCR. Duplicating quality is what one would expect, being several tape generations down from the original masters, but they're on a par with most movie rental tapes. I would strongly recommend using multiple 25" TV sets for showing to large groups. Avoid video projectors, as all home-video systems appear to become fairly grainy when used in conjunction with them. For at-home viewing, any 13" to 25" TV set will suffice.

At $199.95, the set of tapes is not cheap, but it is definitely a good investment if you are among those working toward strengthening the US Amateur Service by bringing new amateurs to it.

For more information, write *Larry Horne N2NY, Ham MasterTapes, 295 Park Ave. South, New York NY 10010.* Reader Service number 478.

WHAT DO *YOU* THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

LETTERS

FATHER MORAN ARRIVES

I need your help in publishing the fact that Father Moran 9N1MM is coming to the US, arriving September 4. This will be his 60th year as a Jesuit missionary.

I am in charge of scheduling his trip all over the US and I am looking for DX clubs in the larger cities who would like to have him for a guest for 2 or 3 days.

Send all inquiries and donations to me.

Edward F. Konop W3WGS
125 Wetzel Rd.
Pittsburgh PA 15209

EGO MISSPELLED

I just read your "Ego" editorial in the February issue of *73* and noted the spelling error: It's spelled E-N-E-R-G-Y. Your subscription-chucking critics are jealous of the energy that jumps off the page at me.

I am at the moment earning radio money as I write. I am a part-time security guard at the dead heart of what was once a huge restaurant empire. It's all being sold off, from semitrailer trucks down to Sanka—desks, pencils, meat massagers, all lying in heaps on the once-busy warehouse floor. It's like visiting the home of a recent widow, before she's cleared out all the guy's stuff. What happened? Shortsightedness, greed, and *lazy thinking*!

One hears of bankruptcies by the score (9 out of 10 new businesses quickly fail, I hear), and people wonder why anyone would even try to start a new business. Or a magazine. As I learned from a bunch of soap salesmen, though, anything is possible—as long as you get off your butt and go after it, rather than sit in front of a TV and wait for somebody to throw success in your lap. I'd like to thank you for saying the same basic thing. You are helping me keep a new leaf turned, to have goals instead of wishes.

Included in my rounds through the moribund imperial seat of Sambo's is their print shop full of Heidelberg presses, paper, a darkroom, etc. I started a college newspaper with some other oddballs and ran it for the two years I was there, so the smells of ink, developer, paper, and wax conjure forth some powerful memories. As I remember what fun the whole process is, from writing and paste-up to printing and feedback, I realize that both you and your niche are lucky to have found each other. Keep having fun. I am with you all in spirit.

Anyhow, I enjoyed your magazine and editorial and thought I'd write and feed your ego. Drat. Now *I* misspelled it.

Lyle D. Gunderson
Santa Barbara CA

BITTERSWEET VICTORY

I read with great interest the March issue of 73. The diaries of those trying to contact STS-9-W5LFL were very exciting to read, even though few were successful.

Unlike some other ham magazines, *73* prints real-people experiences and brings us right into their ham shacks.

I didn't think to write about my W5LFL "contact" but it may be of some interest. At 13:07Z on December 6 (orbit 128) I used an Azden PCS-2000 borrowed from my neighbor next door, Charlie Newman KA4TRF, a 2-meter home-brew quad (K4HDV), and my Curtis KB4900 keyboard, set for 18 wpm. I sent, "W5LFL de W8SJO AR K," to which (during my repeating several times) Charlie came running in the front door (13:06Z) yelling, "You did it! Stop transmitting! He answered you—he said, 'W8SJO, this is W5LFL in the spacecraft, *Columbia*, acknowledging your CW call.'" And then Charlie said he faded away.

I am feeling it was a rather bittersweet victory. Not only because I personally didn't hear it, but also because my "contact" (yet to be confirmed—on this pass in this area—west central Florida—he wasn't heard answering anyone else) resulted in suspicion, denial, accusation of fabrication, disbelief, and alienation of some former hams who I thought were friends.

After the Sarasota newspaper (*Herald Tribune*, January 4, 1984) printed my story, one particular "friend" was in a state of rage. To this day he hasn't spoken. I feel sorry that a facet of ham radio has become a source of envy, jealousy, and animosity, instead of a comradery which comes from mutual respect and admiration of each of our own personal accomplishments.

Most of the hams are very supportive and congenial to me still. Most feel as I do...it really is no big deal...they know the facts. But I wanted to write this to perhaps bring up a point that I doubt has been really considered.

Personally, I'm bedfast most of the time, on oxygen, and ham radio (especially high-speed CW) is really a great hobby for me. I don't understand how we could have become so competitive in our avocation that the human element of fraternal socialization is being lost.

Barry G. Yoder W8SJG
Bradenton FL 33529

BIASED STORY

Your extensive coverage of the W5LFL DXpedition in space leaves me feeling that hams are trying to tell only the good part of the story. Oh, there were a few mentions of transmissions on the downlink. And Wayne Green passed off the negative aspects of the operation with three sentences, ending with, "the usual crapola."

I do not wish to take away from the significance of this historic moment for our hobby, but I came away with a different perspective.

Never in my experience has any event been so well publicized. The frequencies were published far in advance in magazine after magazine. In our area, 2-meter repeater nets went over the game plan in agonizing detail. Goddard and Houston were on HF with complete and updated information. And much more!

Yet, in the Dallas Metroplex area, you would think the whole thing came about on the spur of the moment. One of the really good passes by W5LFL was clobbered in part by "turkeys" on the downlink and "policemen" yelling at the turkeys. I understand it was worse in many other areas. The whole time Owen was in space, the conduct of hams in this area proved that maybe we need an intelligence test for hams, rather than a code or theory test.

Hams had better quit yapping about what a great asset we will be in a "real emergency." If we as a group cannot handle a simple air-to-ground commo exercise, with everything laid out for months in advance, what will we do if that "real emergency" comes up?

I am ashamed to play my tapes of Owen's transmissions to anyone outside the hobby. In a way, we are managing news, by telling only part of the story. We get real upset with the White House or CBS or *The New York Times* if they do that.

Richard C. Rhodes KH6IO
Dallas TX

OVERKILL

A ham operating from space is certainly a great event in the history of amateur radio and worthy of an article or two in any amateur-radio publication. The 22 stories taking up 32 pages in the March *73* seems a complete overkill. 22 consecutive articles on how to install PL-259 connectors would be just as interesting and informative.

Bruce A. Wilke KB0UV
Wapello IA

ECLIPSE NET

A unique opportunity to aid the scientific community will occur on May 30 for hams in the southeastern and mid-Atlantic states. On that date the moon will pass between the sun and Earth, causing a solar eclipse visible across portions of eight states: Alabama, Georgia, Louisiana, Maryland, Mississippi, North Carolina, South Carolina, and Virginia.

Amateur-radio operators in these areas are needed to relay current weather information and predictions for two days prior to the event and to conduct propagation experiments during and after the eclipse. Persons interested in helping out should contact me.

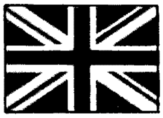
major language spoken, but did you know that besides Spanish over 100 dialects also are spoken? Almost all of them have nothing to do with the Spanish language and have been spoken for thousands of years. You may just get a chance to hear one spoken on two meters sometime when you're down our way! *Hasta la vista* for now!



MONTSERRAT

Errol "Bobbie" Martin VP2MO
PO Box 113
Plymouth
Montserrat
British West Indies

STAR-GAZING TOWARD MARS

The Montserrat Amateur Radio Society (MARS) was founded in 1978 by a small handful of amateurs here on the British Caribbean island of Montserrat, West Indies. It all started when the amateurs decided to pool their efforts in publicizing amateur-radio activities here. The first meeting took place at Foxes Bay at the home of Arnold VP2MH and his beautiful wife Arleen VP2MI. Gathered there were: Arnold Gauthier VP2MH, Charles "Chod" Harris VP2ML, Dr. Konrad Hollatz VP2MF, and Errol "Bobbie" Martin VP2MO.

The first order of business was to elect officers, and this took only a few moments, for the decisions were unanimous. The results were: President—Chod VP2ML, Vice-President—Bobbie VP2MO, Secretary/Treasurer—Arnold VP2MH, and Executive Member—Doc VP2MF.

The total membership immediately rose to 8 when the XYLs decided that they were not going to be left out: Arleen Gauthier VP2MI, Ilse Hollatz VP2MD, Mae Martin VP2MN, and Jean Harris who was not then a licensed ham. Thus began the Montserrat Amateur Radio Society.

Looking at the Society as it is today, it's somewhat difficult for the unknowing to imagine the humble beginnings it had. The first project was introducing amateur-radio classes locally and exposing the general public to amateur radio. This was done in the form of demonstrations, newspaper articles, etc. We immediately applied for and were granted affiliation with the IARU and the ARRL, and Montserrat really came alive on the bands with our operators making world-class scores in the contests and in the pileups.

As we know it today, MARS, with its special callsign, VP2M, is still very active and instrumental in promoting amateur radio nationally and internationally. It is proud of its membership of about 50, divided into three categories: full membership, which entitles one to vote and be eligible to hold office, associate membership A, which entitles the holder to vote but not to hold office, and associate membership B, which is for anyone not a licensed operator but who has an interest in amateur radio, for which there is no age limit.

The Society still has among its priorities amateur-radio training programs, at the end of which there is an exam based upon knowledge of the theoretical aspects of electronics and amateur radio and the capability to receive and send 12 words per minute in Morse code. Through this system there have been a number of new hams on the air.

The present officers of the Society are: Dr. Vernon Buffonge VP2MV, President, a former student of the Society, Sydney St. C. Meade VP2MC, Vice-President, Ursula Sadler VP2MDY, Secretary/Treasurer, also a past student, Victor James VP2MQ, Equipment Officer, also a past student. Executive Members are Dr. Konrad Hollatz VP2MF, Errol "Bobbie" Martin VP2MO, and Perry Britain VP2MR.

The Society's equipment (for its club station) includes an Icom 730, an IC-22, antennas for 2, 10, 15, 20, 40, and 80 meters, a Spectrum SCR-1000 repeater, and a Phelps-Dodge 22' vertical antenna. The repeater is housed in the receiving-station building of the Antilles Radio Corporation, under their auspices, and the antenna is mounted on a 36' pole donated and installed by our local power company, MONLEC. All this is located atop St. George's Hill which rises 1100 feet above sea level overlooking Plymouth and is readily accessible by hams on the neighboring islands.

The repeater and associated equipment were obtained through the perseverance of a few local hams assisted by the influence and integrity of our governor, Sir David Dale, as a gift from Canadian International Development Aid (CIDA) for the purpose of providing communications island-wide in times of emergencies. It is an open repeater except when it is being used for its primary purpose. The frequency is 146.37/.97.

The original surveys as to the effectiveness of 2-meter communications island-wide were carried out many years ago by Alex Kasevich VP2MM and Bobbie Martin VP2MO using an FMH hand-held and a Drake TR-22C portable, and it was discovered that due to the volcanic structure of the islands, 2 meters proved very effective due to the number of reflections we were obtaining; this meant that with a transmitting station located atop any high point, communications could be maintained on a continuous basis.

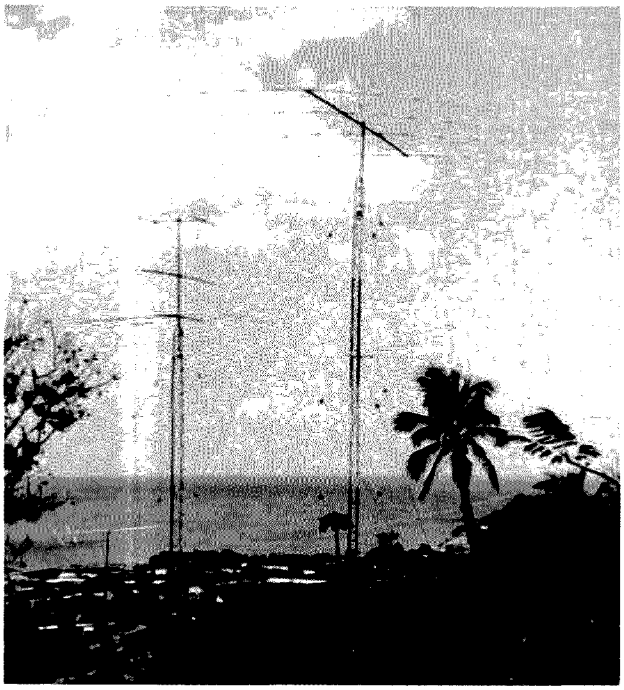
The Montserrat Amateur Radio Society has formed an Emergency/Disaster Team composed of at least 12 operators resident at various parts of the island who are always ready to go into action if required, and there is a daily preparedness net held via the repeater at 2230Z each evening. The net controllers are on a weekly rotational basis to give each the opportunity and training necessary to handle traffic. Each person has been issued an Icom IC-2 hand-held, spare batteries, converters, and other accessories to facilitate efficiency. Along with this daily exercise, there are regular island-wide simulated-emergency tests involving the entire membership.

Because of the valuable service that the Society has been rendering, the local government has awarded it import-duty-free concessions. These are limited to the members only, so visitors to the island are expected to pay the regular *refundable* deposit required by the system here. This deposit is based upon the value of the equipment that the individual is bringing in.

LICENSING AND OPERATING REQUIREMENTS

The island of Montserrat (which is 39-1/2 square miles and is a British colony) has reciprocal-licensing agreements (no third-party traffic) with many countries including the USA and Canada, and the following can prove very helpful to persons wishing to operate here. To obtain permission to operate on VP2M, one should (a) send a letter of application stating your estimated time of arrival, (b) the intended length of stay, (c) intended address while here, and (d) type of operation intended; include (e) a copy of your *national* license, (f) a request for acknowledgement of receipt, and (g) a bank draft or certified check in the amount of US$7.00 and an SAE with funds for return postage (no SASEs as foreign stamps cannot be used here).

Send to The Telecommunications Officer, Ministry of Communications and Works, General Turning Road, Plymouth, Montserrat, British West Indies. Please make your application at least 2 months prior to your intended time of arrival in order to allow enough time for processing and mailing.



The VP2MO antenna farm. (Photo by VE5RA)

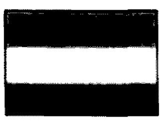
LICENSE JURISDICTION BOUNDARIES

Irrespective of the shady practices very evident today in some areas and the apparent disregard of what agreements really mean, under the reciprocal agreement obtaining a VP2M callsign does not in fact give one the right to export the call. In other words, the callsign issued by reciprocal agreement is *not valid outside of the host country*. If used under those circumstances, it is illegal and is subject to reprisals just the same as when any other law of a country is broken. In fact, a person who obtains permission to operate here is protected only as long as he is in the jurisdiction of this country; as such, he is subject to the laws governing Montserrat and by the same standards is not allowed to operate within this territory until such time as permission is applied for and obtained.

In the case of maritime mobiles, etc., those stations can operate while in international waters using their original calls/MM2, but just as soon as one enters territorial waters, one has to QRT the station until permission is granted (unless he has had prior permission). This topic has been the subject of much misunderstanding in the past, and hopefully this practice will cease to exist. If one is not aware of the requirements, one only has to ask around, for ignorance of the law is no excuse!

This misunderstanding, sometimes deliberate, has led many administrations to change their licensing system, reverting to portable calls or slash suffixes in a move to thwart these offenders, and as a result, much inconvenience has been caused to genuine DXers and contesters alike, and the objective is to stop issuing something that can be exported.

It's a real shame if it results thus, but we only have ourselves to blame.



THE NETHERLANDS

Henk Meerman, Jr. PD0DDV
Zandvoorterweg 33
2111 GR Aerdenhout
The Netherlands

TOP SCORE FROM DUTCH SWL

Dutch SWL Jan Steenbergen NL-213 has a top score on VHF and UHF. On two meters, Jan received the incredible number of 60 different countries, 58 of them confirmed. His best catch on two was Z56DN via transequatorial propagation. On 70 centimeters, Jan heard 35 countries and got 32 confirmations. Jan's best catch on UHF was JA9BOH with Earth-moon-Earth reception.

ATV RELAY

In the region of Doetichem, a few hard-

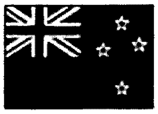
working amateurs are trying to construct an amateur television relay station. When this station is ready, they will place it near the village of Aalten in the eastern part of the Netherlands. Plans are to have FM input on 1275 MHz and an AM-CCIR output on 1252.5 MHz.

P14YK

P14YK is the call of a brand-new station that will be on the air for standard-frequencies broadcasts for the benefit of Dutch amateurs. The station also will broadcast RTTY standard test tones for alignment purposes with a very stable frequency. Furthermore, the station will be able to measure the deviation of signals received from counterpart stations in the two-meter band. Frequencies that will be used by P14YK are 3600 kHz, 144.800 MHz, and 432.800 MHz. The station will be on the air on the following dates this year: January 11, March 14, May 9, July 11, September 12, and the 14th of November. Transmission starts at 1900 UTC. The first operator of P14YK will be Piet van Weerlee PA0YZ.

THE FIRAC

About twenty years ago, those railroadmen who had ham radio as their hobby were united in the international union, La Federation Internationale des Radio-Amateur-Cheminots (the FIRAC). On the first of November of last year, the RANS (Radio Amateurs Nederlandse Spoorwegen), the Dutch division of the FIRAC, was begun. The purpose of the RANS is to strengthen national and international contacts between railway employees. At this moment, the local union has about 30 members.



NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

The space-shuttle flight of W5LFL was not very successful for ZL amateurs, as reported in last month's column. The reasons were no doubt attributable to the late launching of the shuttle, changed work schedules, rest times, and the space vehicle's 2m antenna not facing Earthwards when over our area.

Interested amateurs here were able to obtain orbit information, times, and frequencies for contacts with W5LFL through the ZL 80-meter AMSAT net on 3850 kHz nightly (the net was especially activated for information dissemination), ZL1MO doing a fine job in this direction. Other amateurs made trans-Pacific telephone calls to NASA to get updated orbital data. But all this was in vain because no ZL stations heard Owen transmitting, although many ZL stations tried transmitting on the various uplink frequencies without hearing W5LFL calling first. However, it could be that he copied some of these stations; we shall just have to wait for the list of confirmed QSOs, with interest.

Amateur satellites are an area of growing interest in ZL. We are fortunate to have Ian Ashley ZL1ADX as one of the AMSAT-appointed ground-command stations for the Phase III series of craft. Ian is always ready and willing to provide assistance and information to those who are interested in this facet of the hobby. As the Technician-class license in New Zealand is presently a non-Morse grade, some ZL VHFers in this grade are restricted in their satellite work; they are prevented from the use of Morse as a means of communicating through the various amateur satellites. As a consequence, the Phase-II-type satellites with their 2m uplink and 10m downlink frequencies are still very popular. The Russian RS-series satellites are proving very reliable in this respect.

OSCAR 10 is more of an obstacle as stations require a reasonable UHF SSB signal to access this craft, and this usually means the purchase of a 70 cm multimode rig or a transverter for the HF rig. Nevertheless, an ever-increasing number of amateurs in ZL are equipping themselves for operating through this bird. The tremendous DX capability offered by OSCAR 10 is a powerful incentive—from ZL locations, places as far away as Israel, Kenya, and Helsinki are just in range at various tmes during the orbit, and the ability to make contact with west-coast USA stations most of the time is also a real bonus.

The special-service channels on OSCAR 10 have so far seen little utilization "down under." Suggestions have been made to use one of these to distribute an IARU Region 3 bulletin with scope for local news inserts. This is already being done in Region 1 and seems to be working very well. Information on STS-9 was broadcast from OSCAR 10 and provided a welcome source of times when HF propagation was poor. Hopefully, some use of these special-service channels will be realized in 1984.

At a later date I will try to bring a report on the summer VHF/UHF DX season and the annual VHF/UHF Field Day activities (in February).

Field Day in ZL originated in the early 1930s as a means of testing the effectiveness of the newly-set-up ZL Amateur Emergency Corps, when most active branches went into the field with portable transmitters and receivers operated from dry batteries and stations exchanged messages up and down the length of ZL.

There is still an Amateur Radio Emergency Field Day each year to test the emergency communications network, but the real Field Day activity is the National Field Day in February, when branches of NZART set up stations in a field situation, operate from some form of portable power, and participate in a contest to find the top teams in each ZL district and overall winners for the whole country.

There are trophies for QRP, single operator only, CW only, etc., and last year 60 of the total of 79 branches were activated in the contest. The National Field Day preparations begin with the selection of suitable sites, and these vary from somewhere within city limits to isolated situations away from cities and towns. Once the sites have been selected, the next step is to organize the antennas to be used and prepare them in a knock-down state for quick and easy setting up on the morning of Field Day.

One of the rules governing this activity is that no part of the station may be erected before 10 am on the morning of Field Day, in preparation for the commencement of the first operating session at 1500 hours the same day.

So, once the antennas have been arranged, then the FD controller recruits operators, rigs, the portable power supply, and tents or other portable accommodations for the station and the operators who have to camp out overnight, and arranges a meeting to coordinate all these details. The operators who are manning the station have to attend to their personal requirements for food and sleeping if they are in the overnight group. There are usually a number of operators who attend for their operating periods and return home for overnight.

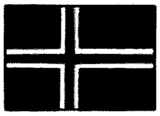
The contest operating periods are from 1500 to 2400 hours Saturday and from 0600 to 1500 Sunday. During that time, stations operate on 80 and 40 meters, phone and CW, under the usual contest setup, exchanging number groups for each contest. The operating periods are on an hourly basis, only one contact for each mode being permissible between stations each hour. The usual arrangement followed by most stations is phone for the first half hour and CW for the second half hour, throughout the contest. Location and propagation as well as operating skills play a big part in each group's activities, but come what may, most branch groups have a ball on Field Day.

There are always many humorous stories told at subsequent branch meetings about the various activities of the participants both on the air and during their rest periods. And also there are the hard-luck tales when rig failures, antenna problems, propagation, etc., robbed a team of their chances in the contest. But regardless of these problems, the really keen ones are always to the fore when the names are being collected for Field Day operators each year because it gives members a chance to get together in a picnic atmosphere, compete against the other branches of NZART, and enjoy themselves in a friendly competitive environment with plenty of time for operating and eyeball rag chewing between operating periods with other members of the team and visitors to the site. Of course, there is also the consumption of numerous 807s, TU1s, or whatever your special name might be for the proverbial bottle of beer, as February in ZL is the equivalent of July/August in the Northern Hemisphere; it is plenty hot and good mosquito weather usually, just the setting for camping out and increasing the liquid intake.

BITS 'N' PIECES

A recent visitor to ZL-land was W6REC/ZL0AJW (Duane Asherman) who has been hitchhiking throughout both main islands, meeting amateurs he has worked and talking to interested groups on the artificial heart project he was associated with several years ago in the States. Duane also is meeting with vintage motorcycle groups, too, as that is another of the interests he has.

While in our area, Duane attended a special meeting of the local branch and gave us a talk on the development of the artificial heart with the team he was involved with in Cleveland, Ohio, some years ago. The talk was received with great interest, and from the questions put to Duane, the members present were appreciative of his giving us the chance to hear his talk and meet him, even though just briefly. No doubt many of those he met made arrangements for QSOs when he returns home to California.



NORWAY

Bjorn-Hugo Ark LA5YJ
3120 Andebu
Norway

Welcome to a new year, and we are just getting used to writing 1984. DX activity has from my side been rather low, but we have managed to work VU7WCY, Laccadives, on several occasions. Unfortunately, this was not a new one, but we got him easily on 40m CW. Operation sounded very smooth and easy although the conditions and the signal were mediocre; the operation went rather easily on both expeditions. I reckon quite a few DXers spent some nice moments working him.

There is one thing that always surprises me: Even the average operator turns out to be a rather experienced operator after a while. The only difference between him and the very experienced operator is the speed and the stubbornness to keep on giving those 59 reports even if he is so tired that he is falling asleep between the QSOs. Others who seem to chat a lot about how great they are but haven't yet proved it in a contest seem to fall apart when placed under those stressful conditions. It is difficult to judge who will be a better operator, but it seems to me that the average serious DXer could do the job perfectly even if a little slowly in the beginning. It's just a matter of will and understanding.

Even if I haven't worked too many DX stations on the lower bands, I have spent some time monitoring 160, 80, and 40 meters and have on several occasions had the pleasure of hearing stations all over the world come through on 160. 80 has been as usual quite good, but not the big burst I have been used to. Other LAs have of course had some nice openings, but it's a matter of being at the right place at the right time. Since I have only the weekends to spend, the QRM level always rises quite a bit then, and one surely gets fed up with hearing those multi-kW guys with big antennas laying two or three kHz away from each other sitting there calling CQ DX hour after hour. Surely they are working some stations, but I'm sure they could have worked quite a few more with a little bit more listening. Very often a local W QSO is taking place on the same frequency, and as a result nothing transpires. You could, of course, go into the same business, but since your signal is not that spacy, they creep up on you, and I sincerely can imagine quite a few more pleasant things to do than messing around on a crowded 80-meter DX portion.

40 meters as always is great—signals pushing through from all areas, and if you have the possibility, get up a sloper, dipole, or inverted V and see for yourself what kind of result you may obtain. It's really amazing how good that band is.

Guess what I've done? I've computerized. Just purchased a CBM-64 and am starting to get familiar with the common Basic language. Looking into back issues of 73 for programs, but all the programs I seem to have use for are made for the TRS-80 or the ABC-80. Why couldn't someone have put in more programs for CBM-64 computers? I'm sure both the editors and the readers would like that very much.

The CBM-64 seems to have taken more of the market among radio amateurs in Norway. I'm really looking forward to a program taking care of my log books, band/mode, countries, and my 5-band WAS, with easy access to the information. The CBM-64 should have the capacity to handle this kind of stuff very easily.

I must say that this computer seems to make me feel more or less the same way I felt when presented with my first amateur station. For some funny reason, I did learn that quite easily though, so even if a few years have been added since then, I reckon I should be able to manage this new challenge as well.

The LA-DX group had, during January, another successful meeting in Oslo. This time they had made arrangements to include a visit of SM0AGD. Eric gave his famous speech based on his DX trip

around the Pacific Ocean. He presented his adventure in a very interesting manner. It was a great pleasure to meet him for the very first time. It is rather rare for us in Norway to be able to greet such accomplished hams on the DX front.

Eric himself used the opportunity to collect members for the NCDXA, and I sincerely hope that they will appreciate his efforts in California

This session was really quite an unforgettable one, and again, thanks to Eric for taking the time to visit us and to the LA-OX group tor the arrangement. It is absolutely recommended that you invite Eric SM6AGD if you wish to have a successful meeting.

We have just heard that several of the guys here in LA-land have been able to work ZL8AFH on Kermadec Island and that he is active even on 40 meters. Surely I can tell what my weekends will be occupied with until I land that new one for me. Actually, we sincerely hoped that Jim VK9NS would be able to go there, but it seems that this has been cancelled for the time being, so we had better concentrate on working the guy who's there.

As you probably know already, Clipperton is due and we are hoping that we'll be able to land it this time; after what I've heard, quite a few others are having the same hope.

I wish you good luck in your achievements both in DXing on the lower bands and in getting a new one.

JUBILEE RADIOLOCATION CONTEST

The 10th Jubilee Radiolocation Contest organized in connection with the 40th anniversary of the birth of the Polish Peoples Army took place in Funka (Bydgoszcz province) in August, 1983. The Commander of the Pomeranian Military District, General Zbigniew Blechman, was an honored guest.

A higher technical standard was achieved in the 10th contest than in the 1st one, when referees shrouded in thickets had to become visible to do their judging. This time, a photodetector coupled with a crystal clock (the work of two designers from Bydgoszcz, S. Wilczynski SP2FLE and A. Owsianny SP2GJI) made it possible to gauge the time of competitors.

Eighty-one men and women competed from 13 district departments of PRAA (Polish Radio Amateurs Association), one contestant came from GFR, and one from GDR partook of the contest. On August 25th, the competition took place on the 3.5-MHz band. The terrain was broken up by hills and woods and was rather difficult. The length of the route for men was 5.5 km. Among 72 starting contestants, 28 did not end the race or went beyond the limit of time. The best men competitors found 5 or 4 senders in about 1 hour and the best women did the same in about 1 hour 43 minutes.

The competitions on 144 MHz were carried out on August 26th. The length of the route was 4.5 km. Also 81 took part this time. The times of the best competitors were from 36 to 51 minutes according to category.

By virtue of scores in both competitions, the best teams were the team of OD of PRAA, Bydgoszcz: Champion of Poland; the team of DD of PRAA, Lomza: Vice-Champion of Poland; and the team of DD of PRAA, Biala Podlaska: Second Vice-Champion of Poland.

Congratulations!

JUBILEE RADIOLOCATION WINNERS
(Champions and Runners-Up)

Individual	PRAA District
3.5-MHz Band

REPUBLIC OF SOUTH AFRICA

Bill ZS6XD, Chairman
Southern Africa DX Association
PO Box 48670
Roosevelt Park 2129
Republic of South Africa

NEWSLETTER, WEEK ENDING 1ST FEBRUARY 1984

One month into the DX year and the bands have been buzzing with activity despite poor band propagation on 10 and 15 meters. Predictions for the next 12 months vary from fair to poor as we slide further down into the low end of the 11-year cycle (which has still another two years to go before bottoming out!). 20 meters, however, should provide some very good openings and will be the DXer's band for many of those rare contacts.

Table 1 provides contact information from Eric ZS6ME which gives an indication of the band conditions. It is expected that the 40m and 80m bands will become more popular as 10 and 15 meters deteriorate.

XT2BR (Upper Volta) has been very active on 20 meters and can be heard most nights in a stateside pileup at 2100 UTC. Even from the back of his beam he can hear us! Also current and active for the next 4 weeks is OM Patrice 5T5RY in Mauritania. OM John CT2FR will be active from the Azores up until 1985. Look for him on 20m at ± 2100 UTC.

WHAT IS SADXA?

SADXA was formed in June, 1983, by a group of South African DX operators with the aim of assisting DXers and newcomers to DX with information regarding DX operations and techniques. The founder of SADXA was the late Mike Sherman ZS6IW, who put forward the idea of a number of prominent South African DXers. Other founder members are Bob Hooper ZS6AEV, Bill Smith ZS6XD/H5AHF, Sam Ford ZS8BRZ, Eric Meyer ZS6ME, and Julius Lieberman ZS6AF/4Z4NY.

The aims of SADXA are many, but among them is the aim of improving amateur activity on the African continent by assisting newcomers to the hobby in countries where equipment cannot be obtained or, if available, is exorbitantly priced, by donating equipment, QSL cards, etc., and offering assistance, where possible, with the setting up of new stations.

DXpeditions are also a major part of the SADXA operations, and the general aim is to have at least one a year. Likely locations are Bouvet Island (3Y), Malawi (7Q), Botswana (A22), Heard Island (VK), and Marion Island (ZS2MI).

To its members, SADXA will provide, in the form of a monthly newsletter, the latest news of DX operations and DXpeditions worldwide, times, dates, and frequencies of operation of rare countries and stations, news of forthcoming events, and general information and news regarding OXing, i.e., QSL info, propagation predictions, etc.

SADXA will also, in the not-too-distant future, conduct an HF net on one of the bands. Details about that will be published in the newsletter. At the moment, a DX Alerting Net is operational on 144.975 MHz in the Witwatersrand area, and we hope to expand that to a 40m net as well.

Also in the pipeline is an "Africa Calling . . ." DX contest in which the aim will be to contact as many stations on the continent of Africa and in the Indian Ocean area as possible during a 24-hour period. An annual trophy, the Mike Sherman Memorial Trophy, will also be instituted and will be awarded to the ham that, in the judgment of the SADXA committee, has done the most for the DXing aspect of our hobby in that year.

As can be seen, SADXA is an organization worth belonging to, and without members to support us, we cannot grow or do what we would like to do. Interested? Write us for application forms!

THE "CHEAP TRICK" TVRO NOW ALSO IN SWEDEN

In my part of the world TVRO equipment is still not very common. *QTC*, the Swedish ham magazine, has not yet published any material about satellite TV, but as a subscriber to *73* magazine during 1982, I devoured articles about satellite TV. I decided with help from these articles to build Dwight Rexroad's "Cheap Trick" (*73*, September, 1982: "The $100 TVRO Receiver," Stephen Gibson) and bring down the Russian TV satellite (4 GHz) Ghorizont, which has 3 transponders. Transponder No. 1 is available in Sweden.

I succeeded with the Cheap Trick and can now watch Russian television. I do not care much for the East Block propaganda, but I do recommend the children's (circus and sport) programs. Before telling you about the hardships with the Cheap Trick, I would like to tell you a little about myself.

My profession is associated with electrical power equipment (motors, generators, transformers, etc.). When I was in school, the transistor was not mentioned in the books! I have always been interested in pictures, but I am a lousy photographer.

On my own, I have tried my best to follow modern technology. My first project was to build a small black-and-white TV set equipped with VHF, UHF, and video input and output. This television set has later been very useful in other projects. As an old man (or at least well over forty), I got my ham certificate in 1971.

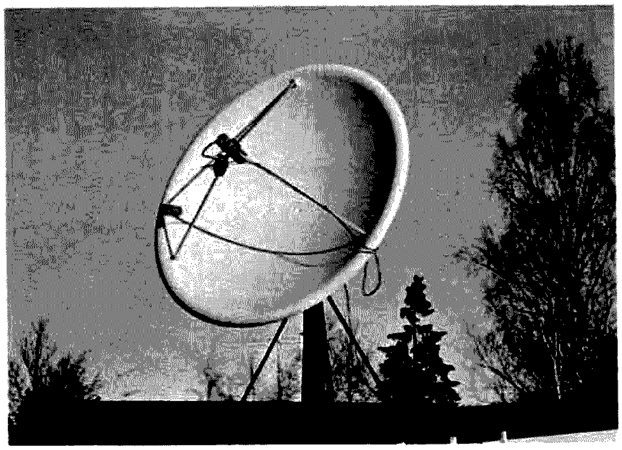
However, I wanted to do something other than operate in voice and code via my station. One by one, I have done projects for gear which no other Swedish hams have! This has meant that I have not been able to discuss them with anyone. The projects have been relatively difficult. They always had their origin in the United States. The projects were:

- 1975: SSTV monitor and flying spot scanner (W9NTP), the only one in Sweden!
- 1978: SSTV keyboard (W6LMD), the only one in Sweden!
- 1983: TVRO, Cheap Trick (Rexroad), the only one in Sweden for the present.

As you can see, I have SSTV very much at heart and I am now on the air, color SSTV, in the 24-sec. mode.

For the Cheap Trick project, Rexroad suggested a parabolic antenna as well as an LNA. Where to get hold of this equipment in Sweden where only the Russian Ghorizont (with factory-made TVRO equipment) can be seen? However, there are 2 or 3 commercial firms which are getting prepared for the real satellite-TV wave around 1985-1986. Fortunately, these firms happen to have hams on their staffs.

OM SM5EEP with the Cheap Trick.



SM5EEP's antenna.

Reception from the Ghorizont. This improved after further aiming of the antenna.

I managed to get a warped antenna and a laboratory LNA (GaAsFET/NE21889) at a very low price. The LNA took 100 mA which is no guarantee for perfect function! Although I had only 40% of Rex's requirements, I decided to go ahead with the project.

I started to obtain the parts necessary in November, 1982, and in December all the PCBs were etched and equipped according to Rex's instructions. A few parts were imported from the United States. The deliveries always arrived promptly. During the winter the project was suspended, but it came alive again in the summer. The antenna was mounted before the summer holidays. The problems began in the starting-up procedure. How and where should I start the alignment?

There was no TV satellite receiver to borrow in Sweden. Nor did I know any owner of a spectrum analyzer or a sensitive counter. I was nearly desperate, but a certain Mr. Mac Palomaki from one of the commercial firms promised me he'd check my downconverter (MRF901). According to Rex's instructions, we made 3.2 GHz. One element that was OK!

I now moved up to the garage roof to test the antenna, the LNA, and the downconverter, which gave 500–600 MHz corresponding to the UHF channels No. 23-25 in the Swedish TV system. If all details functioned and the signal was fed into a TV set, I should get video sparklies or at the best a very bad picture. I got a bad picture which later was aligned to best quality. I continued my work in the garage where Rex's receiver was to be aligned step by step. The UHF tuner was a problem.

The input was altered according to Rex's instructions, but in the output only R20, C10, and C28 were removed. L18 and C26 were replaced by 1000 pF. Consequently, no broadband transformer. Now I got 70 MHz, but pin 1 was fed with about + 1.75 V.

The 70-MHz filter was aligned with an ordinary signal generator with an output of 50 Ohms and a very even output level.

The transformer, T1, caused a lot of trouble in the baseband block. Finally, I found the right connection and the 70-MHz signal could be divided.

The video- and audioblock caused no problems, so I could peacefully watch a perfect black-and-white picture on my homemade TV set. Now I began to align all the circuits starting at the antenna and the LNA. As the RG-59 cable had now been led into my house, the working conditions were now more pleasant!

One last problem to overcome! Ghorizont transmits through the SECAM system while we use the PAL system in Scandinavia. There are, however, now PAL/SECAM TV sets on the market, so of course I got hold of one. By using my VTR, I can now enjoy Ghorizont in color. The quality is 95%, which is very good. The missing 5% is to be found in the warped antenna and the dubious LNA!

Rex, thank you for this project! It took me some time, but I am presumably the only lucky person in Sweden to have experienced this miracle.

THAILAND

Radio Amateur Society of Thailand
PO Box 2008
Bangkok
Thailand

SECOND GENERAL MEETING, 1983

Mayuree Chotikul HS1YL presided. There was introduction of new members, including foreign guests who were attending the meeting.

The society attended the 13th meeting of SEANET Convention at Singapore. 13 representatives from RAST attended, joining some 200 delegates from other countries. The meeting voted that the 14th SEANET Convention, scheduled for 1984, would be held in Malaysia.

Sombat Tharincharoen HS1BV, treasurer, reported that the grand total remaining was 69,706.75 baht [c. US$3,000].

Hans Hoilstein HS1BG, secretary, reported that Victor C. Clark W4KFC, president of the ARRL (American Radio Relay League), died of heart failure on November 25, 1983, and that he was going to send a cable of condolences in the name of RAST to the League.

The Central American country of Belize (for which the prefix is V3) is applying to become a member of IARU World Association and asked for a vote of support from RAST. The meeting unanimously voted to admit the country.

The Asian Institute of Technology (AIT) at Rangsit has given informal permission for RAST to use the site as a place for permanent contest operations.

A total of 161 countries were contacted during the CQ WW CW contest on November 26–27 from a station set up at AIT, and Thailand expects to rank about sixth with an estimated 625,000 points.

For future CW contests, a consensus was sought to use the callsign HS0A which is a good call for that mode. The meeting unanimously approved this.

Election of executive committee members for 1984 resulted in the following: president: Chamnong Phiromphakdee HS1WB; first vice president: Mayuree Chotikul HS1YL; second vice president: Prof. John Hugh Jones HS1AIT; secretary general: Hans D. Hoilstein HS1BG; deputy secretaries: Chaiyong Wongvudhikamchom HS1BL and Sombat Tharincharoen HS1BV; treasurer: Rasdaphorn Bunphithak HS1DC; duputy treasurers: Kamol Choosri HS1DG and Yukluechai Pramitithanakan HS1YP; members at large: Chester Davis HS1AIM, Athit Chuenchamnong HS1EK, Sahas Bhukkaman HS1WC, Banchorn Pramitithanakan HS1JK, Thawatchai Suthavanich HS1HT, and Surapong Srivinich HS1NA; bulletin manager: Hans Hoilstein HS1BG; deputy QSL manager: Tony Waltham HS1AMH; public relations managers: Tony Waltham HS1AMH and M.R. Chakarin Vorawan HS1VV; registrar: Khun Phachern Singhaphalin HS1DH and Kijja Naksomphop HS1KJ; lawyer: Dr. Gunn Nakhamdee.

INVITATION TO VISITORS

The Radio Amateur Society of Thailand holds regular monthly meetings which all foreign radio amateurs and SWLs visiting Bangkok are invited to attend.

The club's committee is pleased to inform anyone who may be visiting Thailand during the first Sunday of any month that the society now meets at the Singha Bier Haus on Asoke Road.

An excellent buffet luncheon is provided, and meetings begin at 11:00 am. A feature of the meeting is usually a talk or demonstration relating to amateur radio, as well as the usual informal get-together.

TRINIDAD AND TOBAGO

John L. Webster 9Y4JW
c/o Department of Soil Science
University of the West Indies
St. Augustine
Trinidad
West Indies

The TTARS welcomed the arrival of 1983, especially due to its designation as World Communications Year and the obvious emphasis that would be placed on communications. The TTARS has always found it difficult to create an awareness in the local public of amateur radio. Trinidad and Tobago, being the most southerly of the Caribbean islands, tend to escape the destruction often wreaked in the more northerly Caribbean islands by the passage of hurricanes.

These hurricanes, although very destructive to homes, property, and agriculture in the Caribbean area, have actually been a benefit to the ham population. The governments in the affected islands have recognized the importance of encouraging amateur-radio operations and have usually extended a variety of privileges to hams, including duty-free concessions on imported amateur-radio gear. This has been very good for the growth of the ham community in this area, where income is often quite limited.

Unfortunately, in Trinidad and Tobago the importance of amateur radio has yet to be appreciated. Many persons either do not understand or do not know about amateur radio, and it is often confused with CB, which is illegal in this country. This confusion has, on occasion, led to the harassment of licensed radio amateurs by the police.

The Executive of the TTARS recognized the benefits that could be derived from WCY and devised a public-awareness and -education program for 1983.

This program took the form of a series of TV interviews with members of the TTARS during which they discussed most aspects of amateur radio, demonstrated ham equipment, and displayed some samples of home-brewed equipment. Throughout the interview series, viewers were encouraged to contact the TTARS, and many did.

There also were radio interviews on the local broadcasting stations, and two of the ARRL films were screened during prime viewing time on the local TV station. The films screened were "The World of Amateur Radio" and the one on Dr. Owen Garriott's planned operation from the space shuttle, *Columbia*. This was quite an achievement for the TTARS, as it was previously almost impossible to get an amateur-radio film screened at all.

The public-awareness program culminated in participation by the TTARS in a large government-sponsored exhibition on communications. This exhibition was held during the last week in October and will be the subject of the second part of this review in my next column.

The TTARS participated in several other events during 1983. The annual simulated-emergency test was conducted in June. Participating stations used only emergency power, and many of the newer hams were introduced to message handling while operating from remote locations.

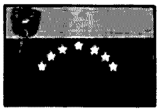
Our president, Nick Percival 9Y4NP, attended the IARU conference in Cali, Colombia, during the first week of July. At this conference, Nick was the official representative of both the TTARS and the Amateur Radio Society of Barbados (ARSB). Later in the year, in October, he once again represented the TTARS at the World Amateur Radio International Conference (WARIC) in Tokyo, Japan. Here Nick had the rare privilege of being the unofficial representative of an entire continent—there was no one else representing South America!

In the first half of the year, the TTARS and ARSB jointly created history by linking the islands of Trinidad and Barbados on two meters. After several years of planning, the 9Y-8P link repeater was installed and has been operating since with varying degrees of success. Details of this system will be the subject of a future column.

While on the subject of repeaters: The local repeater has for many years operated on 146.34/.94 from a remote site in the central mountain range in Trinidad. It actually shares the location with the repeaters for Amoco (oil company). From early in 1983, the repeater was on the air sporadically and the trouble was traced to lengthy power outages in the area causing the backup battery system to become exhausted. On one occasion, the battery charger was damaged by the power fluctuations. Hams had, therefore, become accustomed to finding .34/.94 not on the air. With the introduction of the link repeater system, they simply switched to that frequency until .34/.94 returned to the air.

In mid-October, .34/.94 once again disappeared from the air. After a week had elapsed and it still had not returned, our technical officer, 9Y4AR, decided to investigate. We were all shocked to learn that the repeater hut had been broken into and our .34/.94 machine, standby battery, and charger had all been stolen! Amoco also lost some of its equipment. Fortunately, our duplexers were left behind, probably because they were firmly bolted down to the floor. Up to the time of writing this column, the items have still not been recovered and the TTARS is making plans to purchase a new repeater in 1984.

Well, until next time, 73 and good DXing.



VENEZUELA

Luis E. Suarez OA4KO/YV5
PO Box 66994
Caracas 1061-A
Venezuela

There are several radio clubs in Venezuela. Most are local clubs with small memberships. The Asociacion de Radioaficionados de Venezuela (ARV) and the Radio Club Venezolano are national organizations with memberships ranging in the thousands.

The ARV was established in Caracas on January 24, 1967. It has 43 Seccionales (branches) in all 9 call areas. At this time there are 7 more Seccionales almost ready to be established. As a demonstration of democracy, the ARV bylaws specify that the board of directors' HQ would be in major cities of the country on a rotational basis. That's because the ARV has a dynamic modern organization based on goodwill and hard work.

The current national board of directors includes the following members: Jose YV5AEX, Francisco YV3ARE, Manuel YV5ETV/3, and Nicanor YV5FVN. The general coordinator is Marichal YV5FTU. This board has been on duty for the past two years. The ninth national convention will take place in Guacara, Carabobo State, next July.

This dynamic association manages the most reliable and trustworthy QSL bureau in YV-land. At this time, in Caracas the bureau is managed by Ramon YV5FAA.

Besides all those normal activities of a radio club, currently the ARV members are carrying out technical seminars and, at this moment, they are arranging an expedition to the widely-known Angel Falls. This, no doubt, is a major event for the year. Nevertheless, the ARV fraternity feels that there will be many important happenings during 1984.

The seminars are organized by coordinator Ramon YV5EED, a young medical doctor, and are scheduled four times a year. The central subject is selected by consensus. The first one was "The Two-Meter Band" in October; the second was "Operational Practices" this January. The third was programmed for April on "Satellites."

RADIO BULLETINS

YV5ARV, the ARV's station in Caracas, broadcasts a weekly bulletin on 7,100 kHz every Saturday at 1700 UTC. Each official station at each of all 43 Seccionales joins in. I recommend to all DXers that they keep the list of all 43 stations for future reference (see Table 1). The meeting lasts several hours due to the large number of participants (jammers included).

NETS

The Red Venezolana de Radioaficionados Net is scheduled daily on 3,760 kHz at the following times: 1100–1300 UTC by Eliseo YV1CCV, 1600–1730 UTC by Tirso YV4CYF, and 2200–2400 UTC by Nubia YV3BOS. The Red Net Internacional YV is held Monday to Friday at 0100–0200 UTC on 14,130 kHz. This very well known Latin American net began during 1968 and is currently conducted by Primitivo YV5EPP. Anybody, anywhere, looking for any city in Latin America is encouraged to joint the net. It is also supported by the local 2-meter FM net of repeaters.

At this time they do not sponsor any certificate, but soon they will be announcing something. They own two 2m-FM repeaters, one at Coro (YV1) 147.300 +600 that covers part of the Netherlands Antilles and the second is near Caracas at 147.090 +600. This is also very often activated by DX stations from the Caribbean area and Argentina, too.

Of course the ARV has also a national coordinator for civil defense and is, hence, a link with government authorities in the event of disasters. He is responsible for calling the emergency net if needed.

EXPEDITION TO CHURUM-VENA

The Pomones, aborigines who populate the lands to the south of the Orinoco river, call the widely known Angel Falls "Churum-Vena." This name is mistaken by many people, even in Venezuela, and many times it is heard that the original name of the Angel Falls is "Churum-Meru." In fact, expeditions there are advertised as expeditions to the Churum-Meru, and people think this is the name of the falls. I'll explain, so keep reading.

To make a visit to the Angel Falls, it is necessary to take a plane trip to Canaima National Park. The park has an area of 30,000 square kilometers—almost as large as the whole area of Belgium. Northwest of this park, on the banks of Canaima Lagoon, there is a site facing Hacha Falls named Canaima Camp. The camp is sponsored by a national airline. The Hacha Falls are a wide series of falls similar to those at Niagara but with not so much volume of water. At the foot of the falls, the Carrao river widens to two times its normal width and forms a lagoon. All around this territory there are big, flat-topped, rock mountains whose straight sides rise abruptly; they are named tepuys by the aborigines and plateaus by geologists.

The Canaima Camp has cabins all around the place for the guests arriving at the park. A dining room, bar, and other

Table 1. Branches of the Asociacion de Radioaficionados de Venezuela.

facilities are on the hill above the river bank. Almost daily several excursions depart from the camp to the nearby waterfalls. Most last for a couple of hours. If the weather is good, the airline routes its planes near the falls so that you can appreciate them from the air before landing or after departure. The fact is that if weather is OK to see them by air, it is not good for going to the falls on the ground, for ground travel is by river, and good weather means no rains and too shallow waters for the canoes.

The Churum-Vena are some 40 km southeast of Canaima Camp. The Falls' expeditions go on 5-day round trips up the river during the rainy season when the river is high (from June to December), by motorized canoe. The expeditioners carry coats, sleeping bags, blankets (nights are cold), hats, etc. This *river* is named Churum-Meru, and *that's* why some people think the waterfall name is Churum-Meru instead of Churum-Vena.

The plateau is named Auyan-Tepuy and only very few people have been up there. There is a man that lives nearby and knows how to go up, but he doesn't want to reveal the secret to any except the very few who are guided by him. Most expeditions to the top of the plateaus go from the west side of the plain and take several weeks; these are not recommended for tourists. The 7-day trip to the foot of the waterfalls is not recommended for children less than 15 years old.

The falls start from a river formed 70 meters below the surface of the plateau. The free fall plunges 980 meters—that's 20 times as high as Niagara Falls. The underground river is formed by the rain that falls over the plateau and then seeps through the fissures in the terrain. Most of the area atop the plain is swamp and the air is damp and warm. The plain is accessible by air only from mid-March to mid-May. The rest of the year it is covered by a heavy fog.

On the tepuys small black scorpions live, a species that has existed for 500 million years. Also there is a small black toad that cannot jump; instead, he walks and climbs over the moist rocks. The soil is very poor and there are strange plants unique to the area. Because of poor soils, many plants populating the area get their nutrients from insects; they are known as carnivorous plants. But don't worry; they won't eat hams!

It is atop the Churum-Vena, in the Auyan-Tepuy, that 12 amateurs from the ARV are planning—as I write this—to call CQ on March 30, 31, and April 1. The station's special call is 4M5ARV/6 and they plan to transmit on 6 bands and in three modes. The most important thing is that by the time you read this, an amateur-radio expedition may have taken place to this remote and unique location.

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003, Trades 463-1886 San Diego, 827-5732 (Reno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.

San Jose CA

Bay area's newest amateur radio store. New & used amateur radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Azden, AEA, Kantronics, Santec. Full line of accessories. No sales tax in Delaware. One mile off 1-95. Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.

Boise ID

Rocky Mountain area's newest ham dealer. Call RJM first for AEA, Azden, KDK, Ten-Tec, Butternut, Cushcraft, and more! RJM Electronics, 4204 Overland, Boise ID 83705. 343-4018.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

DUMB WAYNE

Word of a petition I submitted to the FCC having to do with CW was published in abbreviated form in *QST*. Working on the basis of this biased report and without giving the situation much thought, a few Chicken Littles have been yelling wolf, if I may mix my metaphors. Actually, I think that without exception the reaction has been to attack me personally, not my ideas. I'm used to that.

In a classic case of projection, I'm classed as dumb by amateurs who haven't been reading *73* and thus don't understand what I'm doing. Hey, they may not agree with what I think or do, but if they ascribe dumbness as a factor, they're in trouble.

So what in hell is Wayne up to, anyway? Well, it is simple in some ways, but not quite obvious unless you read things carefully all the way through and then think about it. You *73* readers are used to that—indeed, that may be one of the things that sets you apart from the others.

Let's look at the basic situation. We have a dying hobby—amateur radio. Twenty years ago, 75% of the newcomers were teenagers. Now, not only do we have very few newcomers, but of the ones we do have, only about 25% are teenagers. Thus not only is amateur radio drying up as a market and as a hobby, but also it has almost totally dried up as a source of high-tech career people. This last has, I believe, done serious damage to our country.

Now, I suppose that it is quaint of me to worry about the United States. And it is even sillier for me to let my feelings for my country influence what I do. But I see amateur radio as having two major responsibilities to our country—one as a way to attract youngsters to high-tech careers and the other as the only real backup we have for communications in case of a nuclear attack.

Neither of these is a simple matter. But I can't help but take emergency communications seriously when President Reagan tells us that a survivable emergency communications service would be one of the best deterrents to an atomic attack yet. This makes eminent sense.

If I didn't think it made sense, I would not have devoted the last few years to working with the FCC's National Industry Advisory Committee and the last 18 months also to the FCC's Long-Range Planning Committee (for emergency communications). I've made many trips to Washington at my expense for these committee meetings and have been one of the more active participants right from the beginning.

By virtue of my position with the committees and my discussions with the FCC Commissioners, I have a fairly good understanding of the state of the art of emergency communications at present for all of the communications services. I've written about this before, so it should not be a news flash. I don't think I'm letting any secrets out if I tell you that other than amateur radio, there are few real plans for coping with any serious emergencies by the commercial radio communications systems. The worst part of it is that you may imagine that amateurs have some sort of wonderful secret plan. Sorry about that, but there's virtually nothing!

Amateurs have taken the lead in coping with emergency communications needs for many years—and we've done rather well, all things considered. These past emergencies have taught us some lessons which

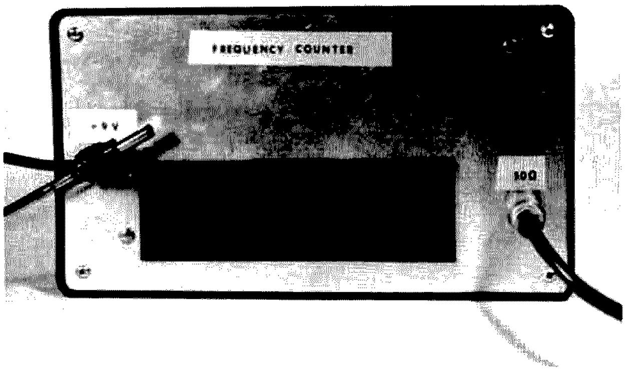
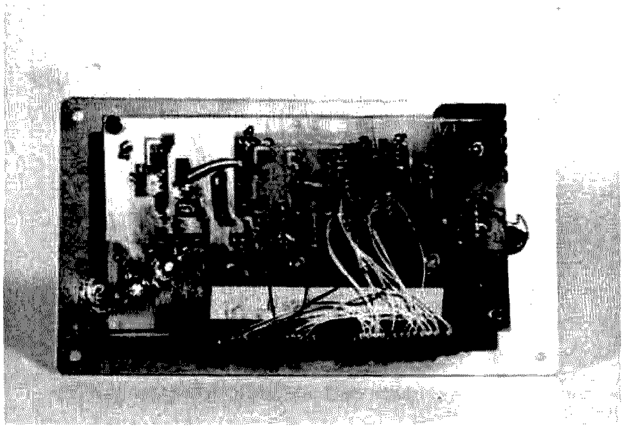
Easy Berardi Building

You can count on this simple frequency counter from Arizona.

Joseph Berardi
14213 N. 38th St.
Phoenix AZ 85032



Front view.



PC board, foil-side view.

This is a construction article for building a very simple, high-quality frequency counter. My home-made counter uses the very popular Intersil ICM-7216-D counter chip and the Fairchild 11C90 prescaler. Just add a few discrete components, some LED displays, another three ICs and we have a very professional-looking frequency counter. I built this counter on a 3″×6″ printed circuit board and installed it in a small lightweight enclosure. The counter design is essentially lifted right out of the appli-

cation notes for both the frequency counter and prescaler ICs.

I will not go into great detail on the operation of the two main ICs; the application notes have all of the necessary information. This counter will accurately measure frequencies from 500 kHz to over 600 MHz.

Operation

The frequency counter circuitry consists of three main sections. The first section consists of a wideband commercial-grade amplifier. The second section consists of two counters to prescale the signal down to a usable frequency since the Intersil maximum operating frequency is about 10 MHz. The third section is the Intersil counter which counts pulses for a specified gate time and then displays the frequency.

Preamplifier

The wideband amplifier has a flat frequency response up to 450 MHz and gradually starts rolling off as the frequency increases. The MWA130 has a gain of approximately 14 dB from 0 to 450 MHz and gradually drops down to 11 dB of gain at 600 MHz.

The high-power amplifier was chosen over the low-power version (MWA110) since the amplifier starts saturating at a much smaller signal level. When the amplifier starts saturating, the harmonics increase in amplitude relative to the fundamental. This confused the prescaler and resulted in erroneous readings. According to the data sheet, the prescaler is most sensitive with a 225-400-mV p-p signal applied to the input. The diodes on the input merely protect the amplifier since the diodes won't start limiting until a 500-mV p-p signal is applied. This signal level would result in presenting a minimum of 1-V p-p signal to the prescaler. This would limit the prescaler to only 450 MHz.

Prescaler

The 11C90 is a high-speed prescaler designed for communication and instrumentation applications. The prescaler can be programmed to divide by 10 or 11. The 11C90 is hard-wired in the divide-by-10 mode. The prescaler has both ECL and TTL outputs, but only the TTL output is used in this ap-

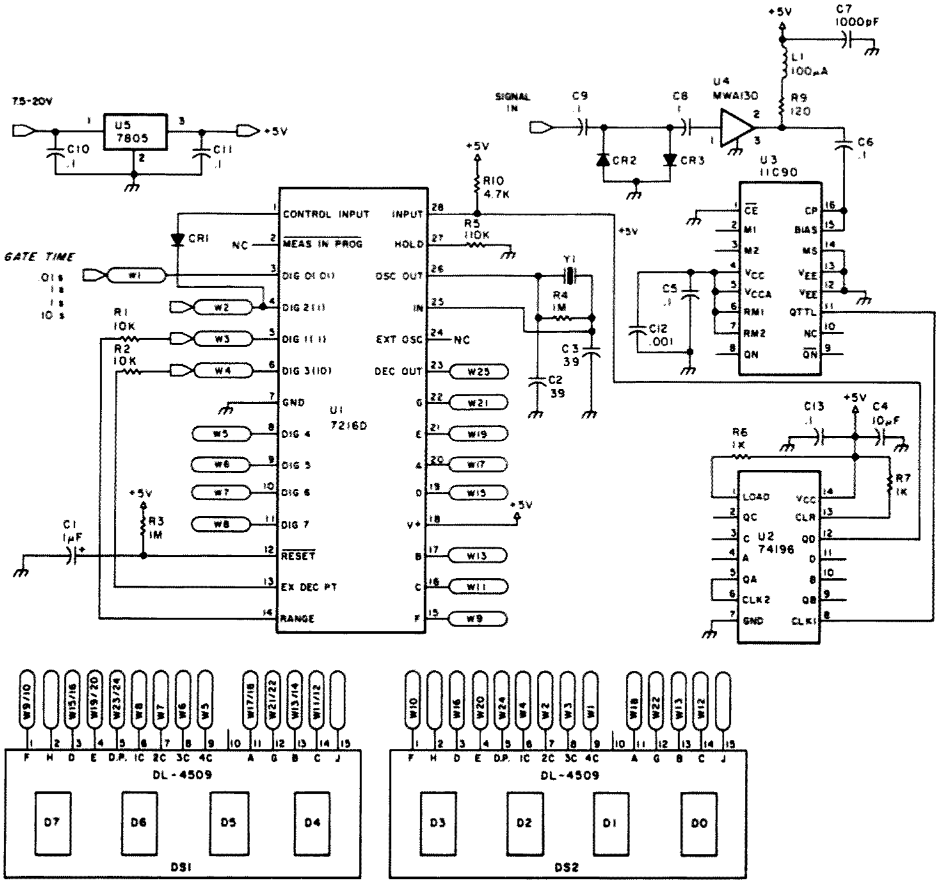

Fig. 2. Frequency counter schematic.

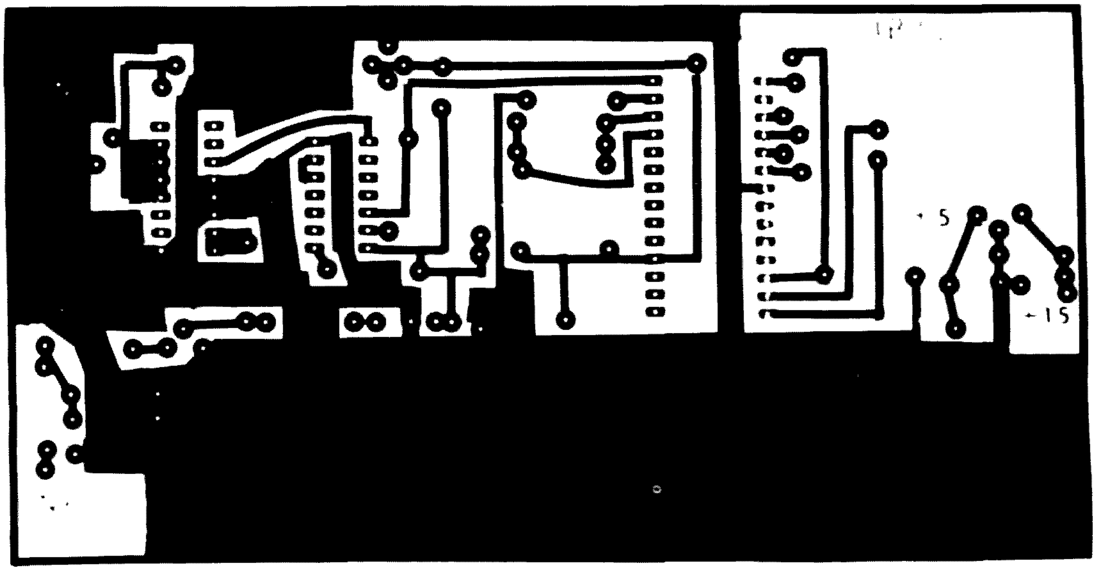

Fig. 3. PC board.

plication. According to the data sheet, this IC has the widest operating range, with a 225–400-mV p-p input signal level (see Fig. 1).

The prescaled output toggles a TTL decade counter; the output of the decade counter is now 1/100 of the original signal and is counted by the Intersil frequency counter.

Frequency Counter

The frequency counter has an internal time-base oscillator which uses an external crystal. A 10,000-MHz crystal was chosen for this application. There are a few discrete external components which tap the signals necessary for determining the counter's mode of operation. The counter has four possible gate times, but only the .1-second gate time is used, for simplicity. A 1-second gate time will increase the counter's resolution to 100 Hz, but will update the display at a much slower rate—which can be annoying if you are looking for rapid changes in frequency.

Construction

I laid out a printed circuit board for the circuitry and used the wire-wrap technique for wiring the displays. The point-to-point wiring method will work just as well for the displays. A wire list is included for wiring the two Litronix red multi-digit reflector arrays. These displays are very inexpensive, but almost any common-cathode, seven-segment displays can be used instead. The prescaler must be soldered directly onto the PC board, but DIP sockets can be used for the remaining DIP ICs. The builder should use the assembly drawing as a guide for installing the parts, and the parts list for determining the component values.

Parts List

U1	ICM7216D—Intersil (common cathode)[1,2]	$20.95
U2	74196	.80

Checkout

This project requires a +5-V-dc supply. A voltage regulator is supplied, so a dc charger (Radio Shack) can be used for power. When using the voltage regulator, the supply voltage can be anywhere between 7.5 and 20 volts but must be able to supply 200 mA of current. The display will light up as soon as power is supplied. Apply a signal to the input and the display will count the input frequency. You will be surprised at the excellent performance of the counter. ■

Don't Grope in the Dark!

Let a simple card-file box be the brains of your own emergency lighting system.

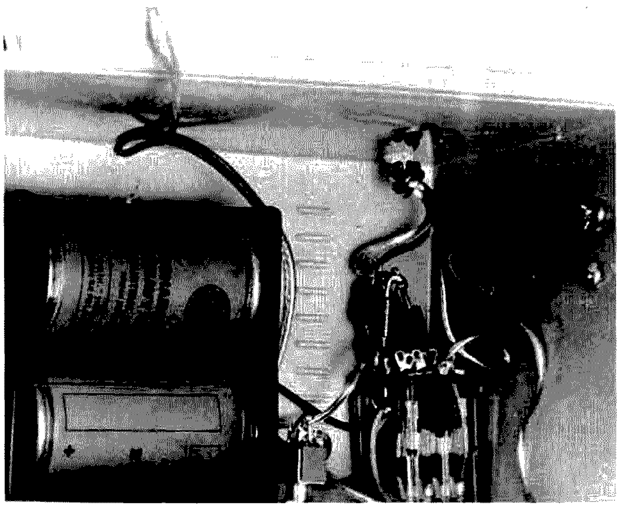
Because a salesman's business lunch was abruptly interrupted by a sudden power failure, a well-known flashlight and battery manufacturing firm was founded. When the main lighting system failed, everyone's attention was drawn to the restaurant's novel flower planters; they contained a crude flashlight. Perhaps this is one of the earliest recorded uses of automatic emergency lighting.

Today, it is common, even required in some cases, to have a form of automatic emergency lighting in hospitals, hotels, businesses, etc. Many homes are so equipped as a matter of convenience.

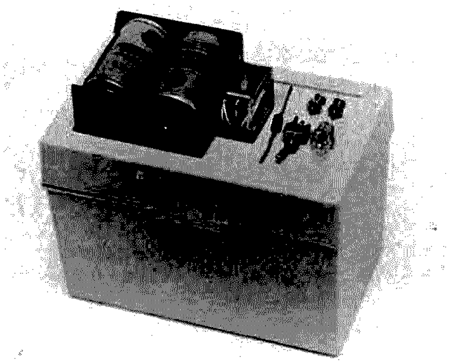
Although sophisticated commercial systems are available which include rechargeable batteries, trickle chargers, test buttons, and power-on indicators, it is practical to make a simple but very effective system mostly out of junk-box parts. The system need not be any more complicated than a flashlight lamp, two dry cells, a relay, and a snap-in battery holder. Two alkaline cells, if the TV ads are believable, should still give plenty of light even after two years of intermittent use, although an annual check/change might be in order.

Regardless of which system you put into your home, ham shack, or cabin, the basic operation is quite simple. When the power fails, the normally-closed contacts of a 115-volt relay complete the circuit between the batteries and light bulb. The bulb automatically turns off and the batteries start recharging (if it is that type of system) when the power is restored.

Gel cells take a float charge quite well, and for that reason are found in many commercial emergen-



Parts placement. The four diodes at the relay form a bridge, allowing use of a 6-volt relay and a cheap ac low-voltage game module. The diode near the top of the box ensures proper polarity of the recharging current.



The parts needed for the project.

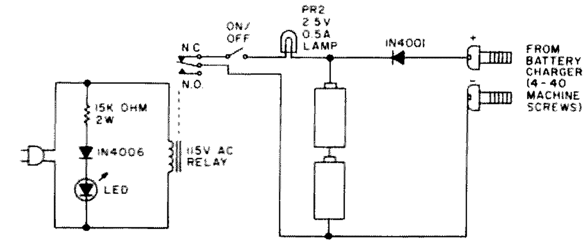


Fig. 1. Schematic of the emergency-lighting project.

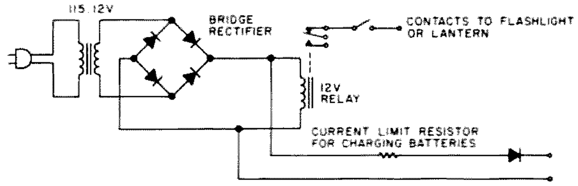

Fig. 2. A variation of the project.

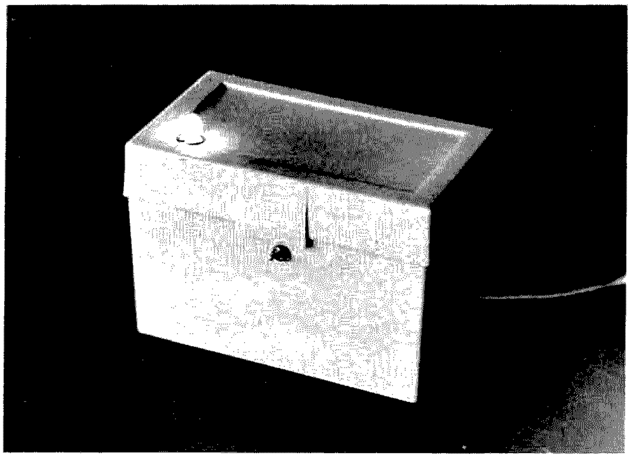


The finished project in action.

cy-lighting systems. Nicads, on the other hand, don't like float charging and should be completely run down before being recharged.

A 4" × 6" card-file box holds the few parts I used. The on/off switch disables the system when it is purposely removed from the power mains. The terminals on the side of the box go to an external charger for the two nicads. As the diagram in Fig. 1 shows, a diode is series-connected with one of the terminals to prevent accidental discharge or reverse charge. The relay contacts could be connected to a lantern through a miniature plug and a closed-circuit jack if you don't wish to construct a flashlight. The relay isolates the 115-volt lines from the low-voltage lighting circuit.

Fig. 2 shows a variation using a low-voltage relay with suitable transformer and provisions for recharging batteries. Don't give up for lack of a 115-volt relay. Perhaps the spare-parts box has an old door bell transformer and a low-voltage relay in it, or a diode and a series-voltage-dropping resistor can make a dc relay work.

There are many possible variations of the basic circuit; this should give you a good starting point.

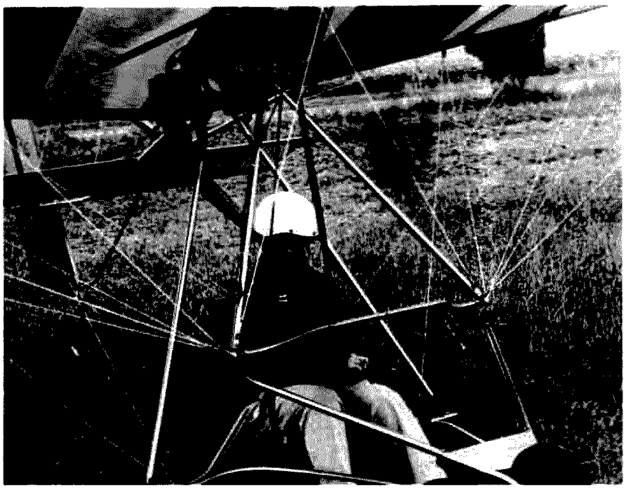
The gentle pitter-pat of a summer rain shower and accompanying sharp lightning bolt doesn't have to leave you in the dark again! ■

Flying High with Two

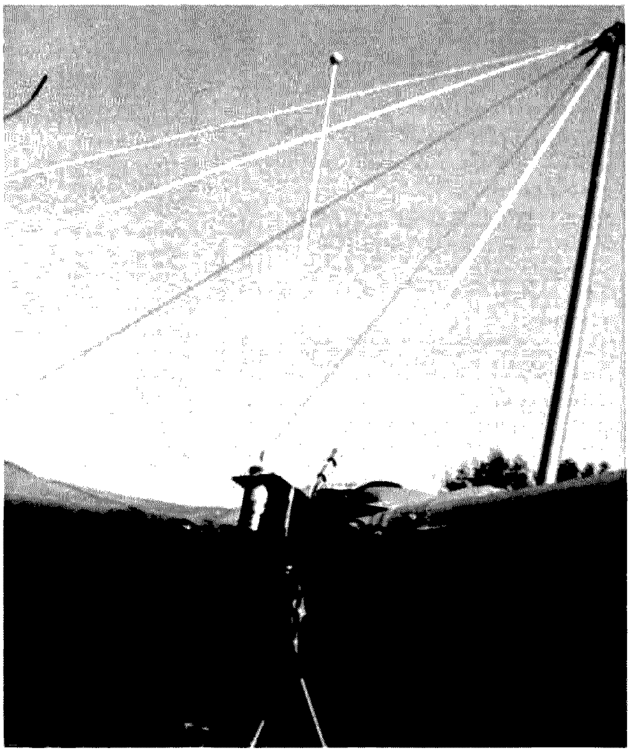
Here's how a hand-held makes for some ultralight Michigan madness.

Ralph E. Taggart WB8DQT
602 S. Jefferson
Mason MI 48854

FM articles in the amateur press seem to cover a wide spectrum—from providing communications for the opening of a new

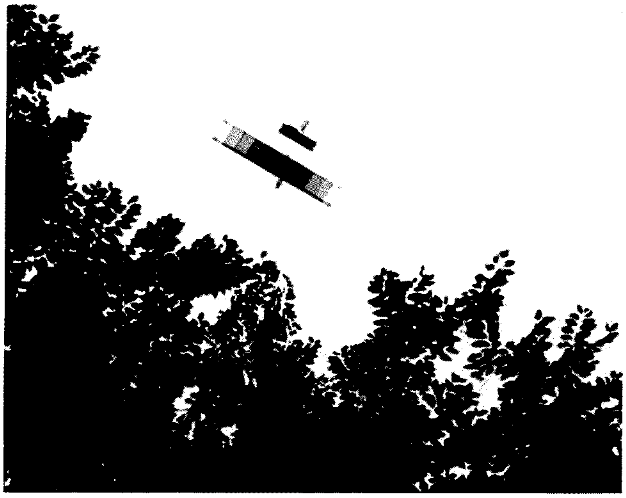


The author intently strapping into the flying harness prior to donning stopwatch, camera, and hand-held. Some of the wire bracing that rigidifies the aircraft structure is clearly visible. The 15-hp engine is mounted below the wing and drives the prop (located behind the wing) through a belt reduction system.



A 2-meter quarter-wave whip anchored to the forward end of the fuselage provides increased range over a rubber duckie partially shielded by the tubular frame of the aircraft.

Don Chubb, my partner in ultralight madness, lifts off in light ground fog for an early morning flight. The pilot's weight is shifted to the rear for takeoff and climb, achieved by simply keeping his legs straight when his feet are resting on the foot bar up by the nose wheel. Movement forward will pitch the nose down while movements from side to side will turn the aircraft in the direction of movement. Pitch control is achieved entirely by weight shift. The side to side movements of the pilot induce the required bank for a turn with the rudder coupled to the harness. Although such a control system sounds strange to a pilot used to the conventional control stick and rudder pedals, it actually feels quite natural and can be learned in a fraction of the time required for conventional flight training.



After taking off and making a 180° turn, the author swings back over the farmyard while climbing to cruise altitude. Although our Quicksilver has a service ceiling of 9000 feet, most flying is done between 500 and 1500 feet—high enough for safety yet low enough to avoid most other air traffic while still maintaining a good view of the countryside. Wind is the greatest enemy of the ultralight flier and most flying is done with wind speeds of 5 mph and below—primarily early morning and early evening. I have built a couple of fancy anemometers to keep track of wind speed, but the leaves of this old tree still provide the most reliable indication of flying conditions.

sewage plant to linking voice-controlled repeaters with blue light. In a sense this is an FM article, but it is a bit off the beaten track in that it describes a new use for those ever-present two-meter hand-helds that seem to be sprouting up like mushrooms on the ad pages of all the magazines.

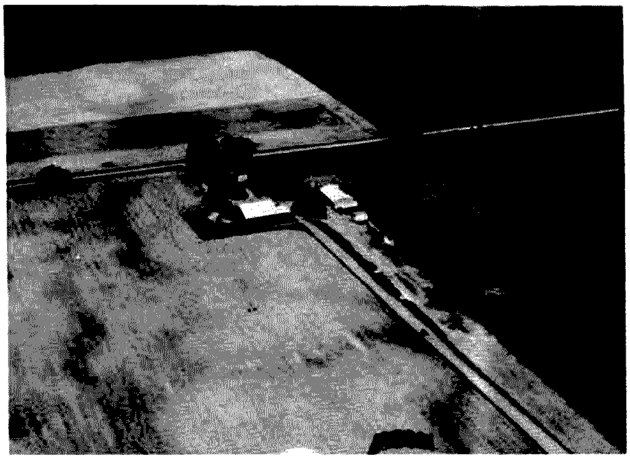
The subject at hand is the marriage of good old VHF and UHF FM with what is perhaps the neatest invention since 20 meters—the ultralight aircraft. It is an application where your FM bands may provide one of the few viable options for good communications (more on that later), but for the moment, if you have a slightly adventurous spirit, hang in there and let me introduce you to ultralights prior to lamenting their communications problem.

First of all, what is an ultralight? The easiest answer is that it is a minimal aircraft—a simple flying machine of aluminum tubing, dacron™, and a small engine—that can introduce you to the thrill of flying with a minimum of fuss, low cost, and, although it might seem difficult to believe, safety. Almost everyone has dreamed of flying at one time or another and radio amateurs are at least as prone to the syndrome as anyone else—perhaps more so. The next time an air mobile calls on 52, just listen to the pileup! The response is due in no small part to the vicarious participation it provides.

In the days of the Wrights and pioneers such as Glen Curtis, the aircraft were constructed of wood, fabric, and wire, and although the activity was far from safe, it was thrilling enough to galvanize a world into the age of flight. Today flying is taken for granted—the thrill is still there and it is certainly safe, but just as certainly it is no longer either simple or economical. Of course it really can't be simple with air lanes crisscrossing the sky stacked all the way to the stratosphere and the requirement of maintaining the safety of those in the air and on the ground. Nonetheless, it is hard to avoid nostalgia for the early days when frail aircraft lifted out of cow pastures, thrilling pilot and spectators alike.

In a sense, ultralight aircraft can provide a return to the best of these rose-colored visions. Ultralights trace their evolution to the hang-gliding movements of the early and middle 60s when intrepid souls, longing to fly on a budget, launched down hills and sand dunes on (or more precisely beneath) rogallos, monoplanes, and biplanes constructed of bamboo and plastic sheeting. That sport blossomed with the aircraft rapidly evolving to sophisticated aerodynamic forms constructed of aircraft aluminum and dacron. Today the sport is dominated by launches from cliffs and mountains in search of the lift to provide flights to extreme altitude or long distances cross-country. Internal regulation permitted hang gliding to develop into a generally sane activity and I have followed its development for several years.

Unfortunately, Michigan has no mountains and even if we had spectacular cliffs and sea breezes, I really couldn't see myself stepping off into the void! Apparently other flatlanders had the same problems, but their response was different. Instead of sighing and putting away the magazines, they responded by attaching engines and wheels to reliable hang-glider designs and ultralights were born! The result has been a



Our rural "aerodrome" photographed from an altitude of 400–500 feet. Not a bad antenna location. Although the gain of the array may not be spectacular, it's hard to complain about the line losses. The reliable communications range is quite fantastic and if the link is marginal, you simply climb a little higher.

surge of reliable, simple aircraft that will fly out of your local pasture. Aircraft-grade aluminum tubing and hardware, stabilized dacron, and light and powerful two-cycle engines replace the hardware of yesteryear while sophisticated application of low-speed aerodynamic principles replaces the "wonder if this will fly" approach of the early days. The simplicity and thrill remain.

At present, regulation is minimal (no pilot certificate or aircraft registration required) if the design meets two criteria—it must carry only one person and it must be *capable* of being launched and landed on foot. Note that I said capable. If the ultralight is a commercial product, the manufacturer will provide evidence of foot-launch and -landing capability and you can stick to your wheels. However, if you designed the bird or modified it and you should encounter an FAA inspector, expect to demonstrate it yourself. If you fail to do so, you will be advised to get a student pilot's certificate and register the aircraft. Stricter regulation is on the horizon, but it will probably be modest with an aim toward maintaining safety while preserving a category for simple recreational aircraft. Present limitations will probably be retained with the addition of standards for maximum aircraft weight, flight training standards, and assurance of familiarity with the Federal Aviation Regulations (FARs).

Ultralights come in a bewildering array of designs, most running between $3000 and $4500 in price. Most ultralights are delivered in the form of a collection of aircraft hardware, pre-drilled and -formed aluminum tubing, and presewn fabric with assembly time varying from 10 to 30 hours.

The key to safety is to stick with those manufacturers who insist that you buy from a dealer who will inspect your work before you fly it. The *Quicksilver*, owned by my partner Don Chubb and me, is a good example of this policy. Manufactured by Eipper Formance of San Marcos CA, it must be purchased through a dealer who will provide any advice you require during assembly (about 20 hours). The dealer will withhold certain vital items—such as the prop—pending dealer inspection of your machine and will test-fly it once assembly is complete. You cannot take full possession of your flying machine until you have completed the dealer flight training course which involves about 5 hours of instruction. One or two hours will get you to your solo while the rest is devoted to developing proficiency.

The plane itself is very simple to fly and after the first few minutes of your solo you will ease out of the shaking-knees-and-white-knuckle phase and really relax and enjoy the experience. The key to safe ultralight flight is rigorous preflight checks on the machine and careful attention to the wind. The latter is an important factor given the light weight of the machine. Our *Quicksilver* has a 32-foot span and 160 square feet of wing area yet weighs only 155 pounds. With a pilot weight of 190 pounds, that is quite a bit of wing for relatively little weight. Most training is conducted under calm conditions. Air currents of 5–10 mph are considered windy and gusty conditions are avoided completely.

The thrill of flying cannot really be described. To really understand it, you have to experience the world opening up as you rise above the tree line at the start of your own private dawn patrol over the rural countryside. Suffice it to say that I spent a good bit of the summer flying every minute I could with nary a thought to the old radio shack!

Once I had become immersed in the ultralight experience, however, I did begin to realize that communications between the pilot and the ground could be of real value. Take training as one example. Needless to say, there is no such thing as dual instruction in a single-seat ultralight. The instructor stands on the sidelines to discuss your progress and problems as you learn proper ground handling, transition to crow hops (short hops into the air down the runway), and finally the solo flight.

Ultralights fly very slowly (typically 20–35 miles/hour) and are constructed of tough materials so you are not likely to hurt yourself in training. However, it is possible to bend some tubing that will cost $$$ to replace. Most of the student problems leading to bent tubing and a confidence crisis could easily be avoided if the instructor could speak to the student during his gyrations instead of afterward. Sounds like a job for radio. Ditto once you are flying regularly. Wind conditions can change, for example, while a flight is in progress. It would be nice if the individual waiting patiently (?) on the ground for his turn could talk with the flier about such weighty matters—not to mention the inevitable "You've been up for 40 minutes, the sun is going down, and I want my turn!"

Cross-country flights have their own attraction; although you will not go particularly far cruising at 30–35 mph, flights of up to 30 miles are quite practical. We usually run a chase car for such ventures, but the car has to follow the roads and is often detoured to pick up gas for the return flight or to get the family outdoors to watch Daddy fly over. Given these realities, a communications link would be quite useful in keeping track of where the aircraft is located, notifying if the flight route has been changed, or, heaven forbid, if you have had to put down somewhere out in the boonies with a problem.

Most ultralights are flown without instruments since they really aren't needed for this kind of flying. If you do carry up an altimeter or air-speed indica-

tor, it is usually out of a sense of curiosity rather than necessity. Radios, however, would be nice. The question is, what kind of a radio. It is here that the unique nature of ultralights presents a problem. Most are powered by two-cycle engines and the pilot environment is noisy, to put it very mildly. The noise is both acoustic and electrical. The former is taken care of by ear plugs designed to deaden impulse-type sound waves, but the electrical dimension is pure poison for an operating radio system. The electrical noise level varies with the engine in use but typically is moderate to quite high.

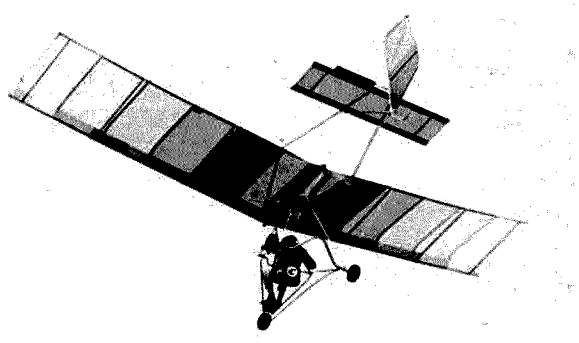
When an ultralight pilot or instructor first thinks about radios, the first step is usually a CB hand-held. Such units lack internal noise limiters and have poor squelch action and cumbersome antenna systems. The newer "rubber duckies" for 27 MHz have eased the size problem somewhat, but they are poor performers at such a low frequency. Even with a 5-Watt ground-based unit, the end result is a radio system that is so noisy and unreliable that it hardly pays to take it up!

Very compact transceivers (even synthesized hand-helds) are now available for aircraft service (108-136 MHz), but these are AM and have many of the same operational limitations as CB units. They also tend to be very expensive. But what about FM? FM would solve the electrical noise problem to a large extent and is characterized by effective squelch action as well. Since I already had a synthesized mobile rig for two meters, this was a logical place to start. Off to look at hand-helds!

I am definitely not a two-meter freak, so the rig for the plane did not have to be microprocessor-equipped —I was not, after all, going to figure my income tax while aloft. I started to scrounge for an old-fashioned crystal-controlled hand-held since these are now considered passé in the better FM circles. A close-out deal of a Pace Communicator MX, complete with rubber duckie, nicads, and charger, seemed the best bet, so off went a phone order to AES in Milwaukee and I had the unit a few days later. A quick check with the wattmeter indicated that my 1-Watt transceiver was putting out 700 mW in the high power mode and about 200 mW in low. What the heck, this did not seem to be an application requiring excessive power and the batteries would last longer. A camera strap was clipped to the securing ring on the hand-held; it went over my shoulder and I headed for the wild blue yonder.

The results of the first test were mixed. On the plus side it soon became obvious that even 200 mW was sufficient for solid communications to the ground mobile, with altitude more than compensating for the inefficiencies of that rubber excuse for an antenna. Although the noise of the engine was definitely modulating the downlink signal, the voice audio had no trouble riding over it with adequate intelligibility. Reception upstairs was another matter, however. Between the engine noise and the ear plugs, there was no way that that little speaker was going to be heard.

That evening was spent on the bench adding an earphone jack. The next morning, complete with an earphone, we had a working communications system. My partner was impressed enough by the tests that he is hitting the code tapes and books to join the party. Refinements now under way include a padded clamp-rack for the radio, a quarter-wave whip mounted above the wing, and a "radio helmet" with a pair of built-in padded phones and a boom mike. Included will be a remote PTT switch on the control bar to minimize the one-handed flying.



The author photographed during a landing approach. Landings are typically made at low throttle with pilot weight shifted well forward to keep the nose down and the airspeed up. Note the bent knees to achieve this attitude.

Although the system was put together for utility communications, it soon became obvious that it had great potential for recreational hamming. Take my word for it: If you give a call on 52 from 1500 feet, you will get answered. It's really fun when the crowd discovers what you are flying and starts preparing the commitment papers while you are still aloft. The crystal complement includes 52 for general hamming, an out of the way frequency for utility communications (never mind where), and a couple of wide-coverage repeaters for the day I have to set down in someone's back 40 and call in the cavalry.

Obviously, if you are an amateur interested in ultralights, you have the communications problem half licked. Although all tests to date have been on two, 50, 220, and 440 MHz would be equally useful although lower-band occupancy might reduce the recreational potential.

A real interesting feature is the potential for recruiting ultralight types to ham radio. Most tend to be highly interesting people and we certainly can't complain if we snag a few of those to swell our ranks. Most fliers would like reliable radio systems and amateur radio can provide just that with a little study. An instructor with a ham ticket need only equip students with a pocket scanner to be able to provide those much-needed instructions at panic time. The advantages are obvious and the canny amateur will work a deal exchanging code and theory tutoring for flight instruction.

One of the things that keeps our hobby healthy is the constant search for new modes as well as new applications for existing technology. There will certainly be lots of ultralight fliers out there—the industry delivered only a few thousand units in 1980, but '81 sales soared quite a ways past 10,000 and most people are still unaware of their existence. Who knows, air mobiles might become quite common. As for me, try 52 and please excuse the background noise—I only worry when it stops! ■

Creason's Do-It DVM

The more Sam builds, the more smart people pay attention.

One of the handier pieces of test equipment for someone who experiments with solid-state analog and digital equipment is a hand-held DVM. I recently needed such a device to measure dc and rf voltages. Since I had no need for either ac or Ohms scales, I chose to save a few dollars by building my own. A schematic of the result is shown in Fig. 1.

The heart of the DVM is an Intersil ICL7106 3-1/2-digit single-chip analog-to-digital converter (ADC) with on-board liquid-crystal-display (LCD) drivers. Powered by a 9-volt battery in the manufacturer's recommended circuit, it provides a basic 0.1999-volt full-scale DVM. Additional components expand the voltage measurement capability and drive the decimal points of the LCD.

The components which are grouped at the upper left of the 7106 (pins 27–29, 38–40) support internal functions: an oscillator, reference generator, auto-zero circuit, and integrator. The interested reader should consult a data sheet on the 7106 to learn more about its internal workings.

The components which are grouped at the lower left of the 7106 (pins 1, 26, 30–32, 35, and 36) provide power, a reference voltage, and the means to connect the voltage to be measured. Switched 9-volt power is applied between V+ and V−. The 22k fixed resistor and 1k trimpot which are connected from V+ to REF LO generate a reference voltage for the converter. The reference is stable because REF LO and COMMON are tied together, and COMMON is internally clamped at about 2.8 volts below V+. The voltage to be measured (0.1999 volts maximum) is applied between IN HI and IN LO (the latter and COMMON are tied together). A 1-megohm resistor limits the current which can flow in response to an overvoltage. Together, the 1-megohm resistor and a 0.01-uF capacitor form a simple low-pass filter. Taps on the 10-megohm resistive ladder between +IN and −IN provide 1.999-volt, 19.99-volt, and 199.9-volt ranges, selected by switch S1a.

With the exception of pin 37, the remaining pins on the 7106 drive the LCD directly. Unlike an LED display, an LCD must be driven by ac waveforms. A dc drive voltage will burn out an LCD in a matter of minutes. The 7106 applies a 60-Hz 5-volt peak-to-peak square wave to the backplane of the LCD. As long as the same waveform

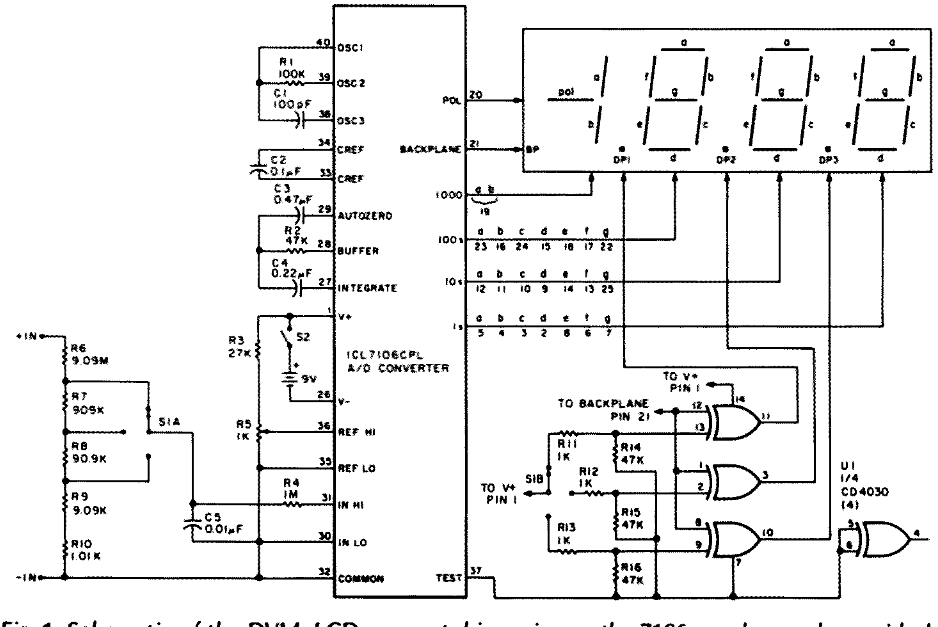

Fig. 1. Schematic of the DVM. LCD segment-driver pins on the 7106 are shown along with the designations of the segments which they drive. No pinouts are shown for the LCD, since they vary from device to device. Undesignated resistors are ¼-Watt, 5% tolerance. R5 is a 10%-tolerance trimmer. R6 through R10 are ¼-Watt, 1% tolerance. R6 is a 90.9k and nine 1M resistors in series. R10 is a 1k and a 10-Ohm resistor in series. Undesignated capacitors are mylar™. C1 is mica. All capacitors are 10% tolerance, 100-volt.

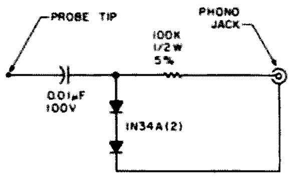

Fig. 2. Schematic of the rf probe.

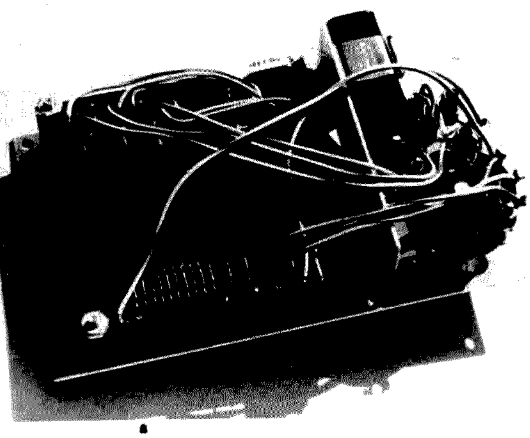

Photo A. Internal construction of the DVM.

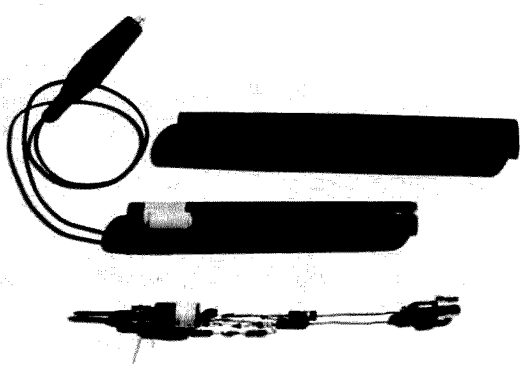

Photo B. Some construction details of the rf probe.

is applied to a segment of the LCD, that segment is off. A segment is on when the waveform applied to it is inverted with respect to the waveform applied to the backplane. The 7106 has internal drivers which accomplish the inversion for the minus sign and each segment of each of the four digits.

The circuit which consists of the CD4030 quad exclusive OR gate, S1b, and six resistors is needed in order to drive the decimal points. One input of each of the three active EOR gates is connected to the backplane drive signal. Depending upon the setting of S1b, the second inputs of two of the active EOR gates are pulled low by 47k resistors tied to ground (pin 37, TEST, is digital ground). These two gates pass the backplane drive signal unchanged, and the corresponding decimal points are off. The second input of the remaining active EOR gate is pulled high via S1b and a 1k resistor tied to V+. This gate inverts the backplane drive signal, and the corresponding decimal point is on.

With the possible exception of the LCD, all parts for the DVM are available from the usual mail-order houses. Also available is an evaluation kit which contains a 7106, an LCD, the passive components to build the bare-bones 0.1999-volt full-scale DVM, and a printed circuit board. The components for the input-voltage divider and decimal-point circuit and the rotary switch and toggle switch must be obtained separately. I used a kit for the convenience of the PC board. However, buying the individual components and assembling them on a piece of perfboard will cut the cost significantly.

Photo A shows the internal construction of the DVM. About ½" of the PC board which is supplied in the evaluation kit is cut away. The cut is made at the upper edge of the pads which accommodate the input jacks. A 1" strip is then cut from the bottom of what remains of the PC board and reconnected at an angle of 90 degrees. Lengths of no. 20 wire restore the connections and provide mechanical support for the strip.

All capacitors except the mica device are mounted on the rear of the board. A piece of perfboard containing the resistive ladder for the input circuit and the decimal-point driver circuit is mounted 1/4" behind the PC board, on fiber spacers. The PC board is mounted 3/8" behind the front panel by means of additional fiber spacers. The entire assembly is held together by 6-32 hardware. The enclosure measures 6-1/4" long by 3-3/4" wide by 2" deep and is of unknown brand. A similar-size mini-box would be a suitable substitute. If a larger enclosure is acceptable, the PC board may be left intact.

Fig. 2 is a schematic of the rf probe, which consists of a resistor, two diodes in series, and a disc-ceramic capacitor. The measured value of an rf waveform corresponds well to the value indicated on the DVM when a 100k resistor is used. A 4.7-megohm resistor might seem the correct choice, given the 10-megohm input impedance of the DVM. However, the ADC is an integrating device which will directly give the rms value of the rectified waveform. Two diodes are used in series to allow measuring rf voltages as high as 30–40 volts.

Photo B shows some construction details of the rf probe. The capacitor is just behind the body of the probe tip, a Radio Shack 274-723 solderless probe tip which is cut to 1-3/4" overall. The component assembly measures 4" from the center of the large portion of the phono plug to the opposite end of the probe tip. The shield for the probe is a 4" length of 3/8"-i.d. copper tubing. The lead from the ground clip is soldered into a notch at the end of the tubing. Taping a 1" "U" into

Parts List for Rf Probe

Part	Value	Part number	Cost
C1	0.01 uF, 50 volt	DC.01/50(J)	.08
D1, D2	1N34A	276-1123(R)	.10
J1		274-346(R)	.45
Alligator clip		270-378(R)	.13
Heat-shrink tubing		278-1627(R)	.50
Phone tip		274-723(R)	.50
Copper tubing (local hardware store)			.50

Parts List for Dc Probe

Part	Part number	Cost
Coiled test leads	278-750(R)	3.99

		10 Ohms (E)**	.50
R11-R13	1k	271-1321(R)	.06
R14-R16	47k	271-1342(R)	.06
Battery connector		– (J)	.10
Case		270-627(R)	2.39
Battery, 9-volt		23-464(R)	.59
S1, 2-pole, 3-position		275-1386(R)	1.19
S2, SPST		275-612(R)	1.69
Knob		274-415(R)	.40
14-pin DIP socket		– (J)	.17
Hookup wire, #22 stranded		278-1307(R)	2.19

* 90.9k and nine 1M in series; $4.50 is cost of nine resistors.
**1k and 10 Ohms in series.
For R6 through R10, prefix part number with TRW/IRC-RN55D.

Substitutes for Parts in Evaluation Kit

Part	Value	Part number	Cost
R1	100k	271-1347(R)	.06
R2	47k	271-1342(R)	.06
R3	27k	271-1340(R)	.06
R4	1 meg	271-1356(R)	.06
R5	1k, variable	43P-1K(J)	1.19
C1	100 pF	DM15-101J(J)	.35
C2	0.1	MY.1/100(J)	.27
C3	0.47	MY.47/100(J)	.45
C4	0.22	MY.22/100(J)	.33
C5	0.01	MY.01/100(J)	.12
Perfboard		84P44WE(J)	2.95
A/D converter/driver		ICL7106CPL(J)	9.95
Banana jacks (2)		274-725(R)	.69
Battery holder		270-326(R)	.30
40-pin DIP sockets		– (J)	.49
3½-digit LCD			

Unless otherwise shown, resistors are ¼ W, 5%, carbon. 100-pF capacitor is dipped mica; others are mylar™, 100 V, with values in microfarads. Cut one 40-pin socket in half, lengthwise, to accommodate width of display. Evaluation kit 7106EV/Kit may be obtained from Jameco Electronics for $34.95.

the lead avoids stressing the solder joint.

The first step in assembling the probe is to tape the exposed leads. Then the component assembly is slipped into the copper tubing so that the free lead from the 1N34A lies on the solder joint of the lead from the ground clip. The phono jack is soldered in two or three places. When the tubing has cooled, the free end of the diode is quickly soldered into the notch. Finally, a piece of heat-shrink tubing is used to cover the tubing. The cable for the probe consists of a piece of RG-174 coax with a phono plug at one end and a pair of banana plugs at the other.

Once the DVM is built, calibration is simple. Select the appropriate range and connect a known dc-voltage source. Adjust R1 until the correct value is displayed. A new 1.5-volt battery is a convenient source. ■

Meeting Ends Make

These ten tips will better your club. Are you friendly or frigid?

Recently, a ham I know moved to an area which has two ham clubs. *"And they're both mighty big bombs!"* he told me.

I asked him what he meant.

"I went by myself to the club meetings—they were on different nights, of course. When I arrived, at both clubs, there were about 20 members already there, shooting the breeze in small groups. *Man, were they unfriendly!"*

But, of all the problems hams face, are unfriendly clubs worth worrying about?

If you need statistics, the answer is that no one knows. While there are more than 2,600 amateur-radio clubs in the United States, no one keeps score of just how many could be rated "unfriendly."

But if you ask—as I have—a number of hams who move often or who travel frequently and visit local clubs, you, too, may be surprised at just how widespread the problem seems to be.

Ask, for example, hams who belong to such clubs as the Naval Postgraduate School Amateur Radio Club in Monterey, California Most of the members are service personnel who move to new duty stations every couple of years or so, joining new clubs across the country and abroad. Several members of the Monterey club have told me of their firsthand experiences about just how friendly or unfriendly some clubs are.

Yet it's a problem that's hard to pinpoint.

Many hams are reluctant—understandably—to name clubs or even cities in which they feel clubs are unfriendly. As one unhappy member put it, "No use me mentioning names and making them still more unfriendly!"

Yet every example and quote in this report came from hams who have faced frigid receptions at various ham clubs.

Another reason the problem of unfriendly clubs is hard to pinpoint is that what makes a club seem unfriendly to one ham may lead another to consider that club as desirable. One newcomer told me, "When I went to my first meeting at this one club, no one even asked me if I wanted to join." But another ham said, "I don't like clubs which try to push you into joining the first time you come."

Still, in spite of such conflicting views and the lack of data on how many clubs could be rated "unfriendly," there are enough hams telling horror stories about unfriendly clubs to suggest it might be wise for all ham clubs—and their members—to take a careful look at themselves, to make sure they do in fact make newcomers feel welcome.

From listening to hams who belong to a variety of amateur-radio clubs in different cities, I've identified ten tips on how to make and keep your club "neighborly," to use the word of a young ham from Iowa I talked with recently.

The first tip came from an experience told to me by a ham on the day after his first visit to a club.

"I walked in at 7:25 pm, five minutes before the meeting was to start. A couple dozen members were already there. A few of them were talking to someone next to them. The rest were silent—just sitting there, not saying a word. Only a few glanced at me as I stood at the door, trying to figure out where to sit. No one invited me in. Not a one said anything to me or even gave me a nod."

Tip #1: Ham clubs should designate two or so of their members to be greeters, to welcome newcomers.

Greeters don't have to be—shouldn't be—formal. They don't have to stand at the door, wear neckties and jackets, have a set patter, escort newcomers during the entire meeting, or such. Instead, greeters should simply keep an eye on the clubroom door as they mix with other members; when they see an unfamiliar face, they

should go over immediately, introduce themselves, and initiate the usual ham talk. Such face-to-face meetings need not be much more structured than the usual on-the-air QSO.

Once the greeter has learned a few of the special interests of the newcomer, he or she should introduce the guest to another member with similar interests. The point is, of course, to make sure first-time visitors are not left on their own to search out members with whom they may feel comfortable.

To prod my friend to tell me more about that club which ignored him as he walked in to its meeting, I asked, "So what did you do?"

"There were just three empty chairs. They were all together, at the far end of the table. I walked down to them. No one asked me to sit or anything. I waited a few seconds and then sat down. The guy next to me gave me a glance and then went on with his small talk to the ham across the table."

I prodded again: "Not very friendly, huh?"

"After waiting what I thought was a proper length of time for a break in the chatter, I introduced myself to the two guys. One said 'Hi,' gave me his call, and went on with his talk about the weather or something."

Tip #2: All club members should be urged to talk with newcomers.

This is so basic it's almost embarrassing to mention. But of course the problem is *not* that hams are socially unsophisticated, not knowing that they should talk to others. Rather, many of us get so involved in our own discussions of hamming that we may ignore others.

Hams, like many people everywhere, can benefit from increasing their sensitivity to the interests and needs of others, especially to newcomers. That will not only make recent arrivals feel welcome, but also it will help you feel better. As American humorist Philander Johnson wrote, "New friends leave the heart aglow."

My friend's concern about unfriendly ham clubs sounded deep, so I urged him on: "Meet anyone later in the meeting?"

"The meeting started out with the usual self-introductions. You know, they went around the room, each ham giving his or her name and call. When it came my turn, I said just what the others had—my name and call—adding that I'd just moved into the area."

"Did that spark any interest?"

"Not a bit. The self-introductions continued."

Tip #3: Make all introductions worthwhile.

Many clubs open meetings with self-introductions which are given quickly and briefly; many are muttered, some are embellished with bits of "in" humor, getting laughs from only a few. Such self-introductions become so routine they are close to meaningless.

I asked several long-time members of various clubs, "What good are those introductions?" Answers were limited.

"Gets members participating." (Saying just three or so words equals participation?)

"We get to know who's here." (To find that out, most members have already looked around long before the self-introductions.)

"Lets everyone have a moment in the spotlight." (Hams, with all their distinctive skills and achievements, need that?)

Introductions should not take much time of a meeting, but they should be valuable. Members should be encouraged to speak slowly, clearly, and add a few words about their recent activities, interests, or such. Setting a limit is wise—the membership guide for one group states, "No more than 20 words."

One good technique for improving introductions was suggested by Gene Piety KH6PP, now living in Santa Cruz, California:

Tip #4: Have a greeter introduce newcomers.

Only a few words are needed: "Here's a ham new to our area, interested in home-brewed rigs. He's just moved here from (. . .). His name is (. . .); his call is (. . .)."

An interesting technique to add friendliness to clubs was initiated by Bill Webb NK6H, of Monterey, California, when he was president of his local ham club:

Tip #5: At each club meeting, have one or two members give, say, a 5-minute autobiography, preferably with slides, artifacts, or such, detailing their shack and their interests beyond hamming.

These, of course, should not be formal speeches. Brevity is the key.

There is the problem that some members may be hesitant to give such talks. Perhaps they overlook the fact that when they're A3-ing, there may well be far more people listening than are at their club meetings. So start by asking those members who seem to like to get up and speak. Also ask frequently for volunteers — that apparently shy one may well be masking a stimulating speaker! After a few members have presented themselves, most of the others will usually want to take part, too. Certainly some may be strictly against getting up to give such talks, but there's no need to pressure them into participating.

Another idea to help clubs welcome newcomers came from this story told by a ham in central California—that's as close as he wanted to identify this club.

"After my first meeting, when I got home, I realized I really hadn't learned much about the club. Sure, I heard the treasurer's report—they had several hundred dollars in the till. But since they didn't say what activities they're into, I couldn't tell if they had money or not. The president said the newsletter gave details about an upcoming field day, but I didn't see a copy—they were mailed to the members' homes. And I met a couple of guys, but too fast for me to remember all their names and calls."

Tip #6: Give information packets to newcomers.

The packets should include, at the very least:

1. List of members with their calls, addresses, and phone numbers.
2. List of committees—members and tasks.
3. Minutes of the last few meetings.
4. Copies of recent newsletters.
5. Schedule of activities.
6. Repeater frequencies for the area.
7. A copy of the club's constitution.
8. Instructions on joining.

Other materials some organizations give to new members—although I know of no ham clubs which provide these—include:

1. Local sources for equipment, parts, services, etc.
2. List of names of members' spouses and children (helps develop family involvement).
3. History of the club.
4. A few copies of articles about the club — say the top three articles published in the last year or so.

Here's the experience of another ham. It's valuable because it points to another tip to help ensure that visitors don't come to just one of your club's meetings and then never show up again.

"The club's secretary gave me an application form for joining the club. I

thought that was a nice touch. Later, I read the application. It included a statement I was to sign, agreeing to abide by all provisions of the club's constitution. That seemed overly formal, but I figured, well, maybe they have a good reason for that provision. Only they hadn't given me a copy of the constitution. And when I asked for a copy, I was told it was being revised and would be ready in a month or so, but not to worry, just go ahead and sign anyway."

Tip #7: Give newcomers a copy of the constitution, rules, by-laws, or whatever guides your club.

Even if your constitution, for example, is being revised, prospective members should be given a copy of it so they'll know the ground rules as they are at the moment. Many prospective members consider such documents quite seriously. They like to know what they're getting into—how decisions are made, dues increased, leaders selected, and such. They *don't* agree with the advice of American writer George Ade: "To ensure peace of mind, ignore the rules and regulations."

An officer of one ham club I visited handed me an application form on which two members were to sign as "sponsors" of new members. But since I didn't know anyone in the club and since neither that club officer nor that form told me how to get sponsors, membership seemed to be blocked. Therefore:

Tip #8: If new members are to be sponsored by established members, make sure information on how to get sponsors is readily available.

Of course, if a member brings a newcomer, he or she most likely would be a sponsor and would usually help find additional sponsors, if needed. But clubs which require sponsors should have a method for providing them for prospective members who come on their own to a club's meeting. Greeters or club officers might be appropriate sponsors.

Another problem for newcomers is highlighted on the second page of *The Radio Amateur's Handbook*: "One of the *first obstacles* for a person seriously interested in amateur radio is finding a local amateur to provide assistance. This volunteer amateur is called an 'Elmer.'" (Emphasis added by author.)

Finding an Elmer should certainly *not* be an "obstacle."

Rather, an Elmer should be immediately available to every newcomer—to prospective hams, to new hams, and—just as important—to established hams who move into a new area.

But there's an additional problem with many Elmers today. They may tell a newcomer something such as, "If you need help, give me a ring."

That's not really much of an offer of help. Elmers should do more than that. One good example is J. V. Rudnick K6HJU of Felton, California, who has been Elmer to scores of hams. He drops by a new ham's shack a few days after they meet. He comes with tools, ready to spend a few hours, if needed, to help find electrical interference, check out a new rig, select an antenna location—all examples from his recent Elmering.

Tip #9: Ensure that every prospective member gets an Elmer—an active Elmer, a real Elmer.

Finally, the essential tip:

Tip #10: Evaluate your club and yourself: How do you think newcomers would rate you?

Are you and your club friendly or frigid? ■

Tester Project: England '83

Wherein you flash-chance transistors, chap.

Reprinted by permission from the May, 1983, issue of *Radio & Electronics World*, 200 North Service Road, Brentwood, Essex, CM14 4SG, England. The transistor tester was designed by R. A. Penfold, 12 The Crescent, Hadleigh, Benfleet, Essex, SS7 2HF.

Transistor testers normally fall into one of two categories: basic units where a flashing light indicates serviceable devices, or calibrated metering circuits which give a rough indication of current gain. Our design is really a cross between these two. It uses a flashing 10-LED bar graph to indicate whether or not the transistor is usable—the number of LEDs activated gives an indication of current gain. This novel system enables checks to be made very rapidly and easily, as well as providing more reliable and informative results than a single-LED tester.

Design

The basic setup used in the transistor tester is shown in Fig. 1. Schematic (a) shows the block connections for testing PNP transistors and (b) shows the slightly different arrangement needed when checking NPN devices.

Looking first at the PNP mode, a low-frequency oscillator drives the base of the text device via a resistor which sets the base current. The transistor is thus switched on only when the output of the oscillator is in the low state (it is cut off when the output is high). A zener diode is used to give a stable output voltage from the oscillator so that a reasonably stable base current results.

The bar-graph driver and display are fed with the voltage developed across the collector load resistor. Circuit values are chosen so that a very low gain device produces only sufficient voltage to activate one or two LEDs, while a very high gain device will activate all ten. So, with a serviceable device being tested, the LED display should flash on and off, and the number of LEDs will indicate the gain.

In the NPN mode, an oscillator, zener stabilizer, and series resistor are again used to pulse the base of the test transistor with a reasonably

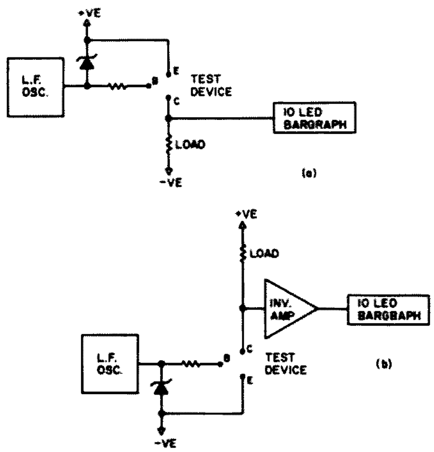

Fig. 1. The two basic circuit configurations for testing NPN and PNP transistors.

CIRCUIT DESCRIPTION

The full circuit diagram of the transistor tester is shown in Fig. 2. The LF oscillator is a straightforward 7555 astable, operating at a little over 1 Hz. IC1 is a CMOS version of the 555, used primarily because of its low current consumption. In order to permit the use of very simple NPN/PNP switching, separate NPN and PNP test sockets are used, as well as separate zener stabilizers and base resistors. In the prototype, there was a tendency for very high gain PNP transistors not to cut off properly due to the output of IC1 going slightly less than fully positive on the appropriate output half cycles. This problem was completely overcome by making R4 and R5 a little higher in value, and adding R3; which have no significant effect on circuit operation in other respects.

The closed-loop gain of the circuit is accurately set at unity by R10 and R13. R6, R7, R11, and R12 are close-tolerance components so that consistent results are obtained when moving from PNP mode to NPN.

R8 and R9 form the load resistance for NPN devices, while R14 and R15 are the load resistance for PNP devices. The value of R15 sets the operating-current range of the unit. It varies from about 450 uA, with one LED switched on, to around 12 mA with all ten activated. This gives a reasonable operating current for low gain devices, whilst removing the need for excessive current flow when high gain transistors are being tested. R14 is added in series with R15 merely to provide additional current limiting if a closed-circuit device is checked.

Switch SW1 is all that is required to give NPN/PNP switching. It switches the input of the display circuit to either the output of IC2 or the PNP-collector test socket (note that IC2 has a class A output stage which enables its minimum output voltage to swing down to near the negative supply potential).

The display driver is an LM3915N integrated circuit (IC3), which is similar to the popular LM3914 device. The LM3914 has ten *linear* LED threshold voltages, whereas the 3915 has a *logarithmic* scale with the LED threshold voltages at 3-dB intervals. This enables a wider range of current-gain values to be covered, with the maximum value being about thirty times higher than the minimum. R16 controls the LED operating current, and the specified value provides around 4.5 mA.

stable current. However, there is a minor complication in that the voltage developed across the load resistor is relative to the positive supply, whereas the bargraph driver requires an input voltage referenced to the negative supply rail. A unity-gain inverting amplifier is therefore used between the load resistor and the display driver to give a suitable input signal for the latter.

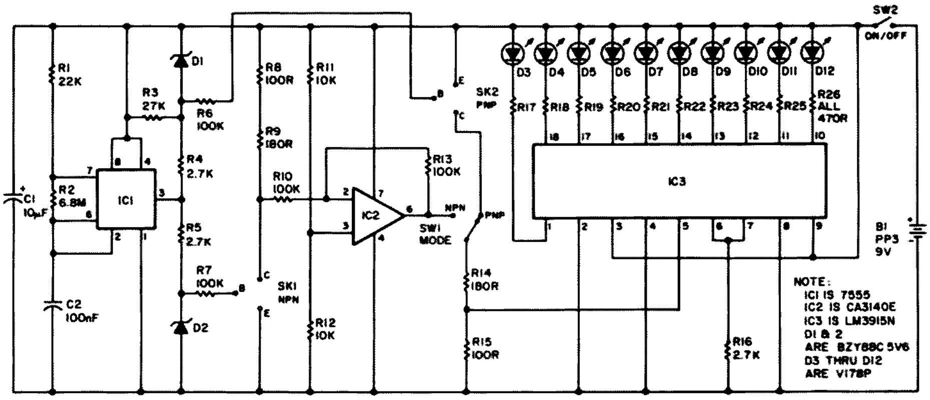

Fig. 2. Complete circuit of the tester.

Construction

Practically all the components are fitted on the printed circuit board, the only exceptions being the battery and the sockets. Details of the PCB wiring are provided in Fig. 3. If the specified case is used, the two cutouts in the corners of the board are necessary to mount flush with the pillars inside the case.

It is essential that the mounting holes for SW1 and SW2 are accurately positioned on the front panel. One way of ensuring a good fit is to use the board as a template. It is probably best to initially drill small guide holes of about 1 mm in diameter.

Construction of the PCB is quite easy, but note that IC2 has an MOS input stage. Although IC1 is a CMOS device, it does not require any special handling precautions. The tags of SW1 and SW2 should be pushed right down into the board before these components are soldered into place.

The test sockets are two groups of three 1mm sockets, and provided each set of three is tightly grouped, it will be possible to fit most transistors directly into these without difficulty. A set of test leads can be used to make connections to transistors that will not plug into the sockets. The tags of the sockets should be bent at right angles so that they do not come into contact with the PCB when it is fitted into the case.

Operation

In use, the mode switch is set for NPN or PNP, and the test device is connected to the correct sockets. If the device is functioning prop-

erly, the LED display should flash on and off with a suitable number of LEDs being switched on. It is a good idea to test a number of transistors of various types, which are known to be fully operational, so that you know the approximate number of LEDs that should be activated when testing a suspect device.

If the LED display lights continuously, this indicates that the device under test is closed circuit, but check to be sure that SW1 is in the right position and that the device is connected correctly. If not all of the LEDs switch off, this indicates that the test device is faulty and has a high leakage level, but again, check that it is connected correctly and that SW1 is in the right position. Also, do not hold the transistor in the test sockets touching the base and collector leads. This could supply a small current into the base of the component giving a high enough collector current to activate one or two LEDs. If the display fails to light at all, it indicates that the transistor under test has gone open circuit. ■

Sounds Good to Me

Two Texans put together "73 Morse R/T." It's the best Basic VIC-20/C-64 code program you will ever see.

Three things plague Morse code transmit/receive programs. First, the good ones are expensive. Second, the inexpensive ones don't generate good-sounding Morse. Finally, most Morse programs you enter yourself are in Basic and are too slow to generate or copy well-spaced Morse.

So what have we here? True, it's Basic that you must enter yourself, but before you dismiss it as just another Morse program, consider that "73 Morse R/T" has been carefully assembled to make maximum use of Commodore Basic.

Because variables improve program speeds, the program sections using numbers have been created to use the faster variable method. Morse spacings have been carefully guarded, and this program generates the best-sounding code possible in Basic at speeds from 5 to 50 wpm.

73 Morse Receive/Transmit allows type-ahead buffering of up to 255 characters and three (or more) 255-character message buffers into which may be placed a CQ, station brag tape (rig message), and QTH information.

Additionally, a simple interface schematic is included in this article. With it, your Commodore VIC-20 or -64 can be connected to your radio and be used with 73 Morse R/T on the air.

Two items of caution before describing this program in detail. First, if you make program modifications, add no line number preceding line 200. Any line appearing prior to 200 must be processed between each character sent by the program and even a Remark statement will deteriorate the sound.

Second, we suggest you avoid attempting to enter the Receive mode of this program until you have constructed the interface. If you engage the Receive option without an interface attached, 73 Morse R/T will lock and you will be unable to return to Transmit. Until you have constructed the interface (or attached a suitable one), place a Remark (REM:) at the beginning of program line 255 to prevent the lockup. Remember to remove it when you connect an interface.

73 Morse Receive/Transmit supports the following amateur CW prosigns:

Prosign	Key
AR	)
KN	=
SK	–
AS	@
BK	*
BT	=

In addition, Morse error (eight dits) is sent when Return is depressed or an undefined key is struck. The Run/Stop key is an exception and acts as a Break key; if accidentally depressed, type "CONT(inue)".

This program features a 255-character keyboard buffer. If the 255-character limit is exceeded, excess entries will result in the "string too long" error message. Should this occur, enter "CONT" to resume.

The Delete key may be used in the normal manner to make changes and corrections, providing the character to be corrected has not been or is not being transmitted at the time of the attempted correction.

A transmission may be aborted by using the Clear/Home key, but can be called only from the Transmit mode. Exercising this function results in a clear screen and loss of the buffer contents.

Six 255-character buffers

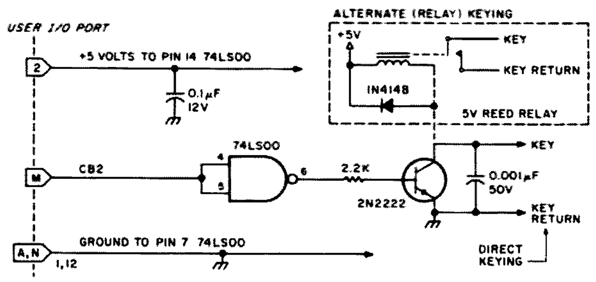

Fig. 1. 73 Morse transmit schematic.

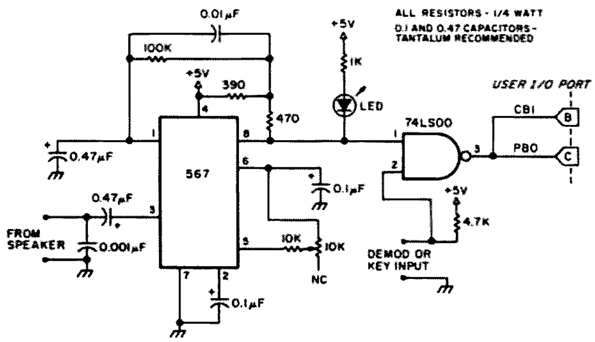

Fig. 2. 73 Morse receive schematic.

are included with 73 Morse R/T. All are accessed from the Function Keys on the right side of the VIC-20 or -64. Earlier, only three were mentioned. The reason for this is that to be useful, one buffer must hold the station callsign input, another the callsign of your station, and the third an HW CPY link.

Although more than suggested data could reside in the preceding three buffers, their function limits the length of the contents. Feel free to change the contents of any buffer (Function Key) as you wish. Details of how this may be accomplished can be understood from reading the following documentation sections.

F1 will send the message contained in program line 310, which in this case is CQ. Any message up to 255 characters in length may be placed in this buffer. You are limited in line length, however, to the default limits of your computer (88 on the VIC-20, 80 on a -64). If your message exceeds these lengths, it is suggested that you add a second line number (in sequence) to complete your message, as illustrated in the link example in program lines 360 and 361. Notice that GOTO 45 appears at the end of the last line of buffer text only and that line contents must be linked as "KS=K$+" on additional lines.

F2 allows you to enter the callsign and name of the station with whom you are engaged. These entries may be left blank, or to change the data you may recall the option and enter a single quote (") when the information is requested. Once a name or callsign has been entered, entering a null will preserve whatever data resides in the memory for those categories.

F3 will send "(his callsign) DE (your callsign)" if a callsign for the station being worked has been entered. Your call must also appear in program line 330.

F4 sends the QTH or other message contained in program line 340.

F5 will transmit "SO HW CPY (name)? (his callsign) DE (your callsign)" followed by the invitation to transmit "(K)". This function demonstrates how two (or more) Function Keys can be linked (concatenated). In this example, F3 is called by F5.

F6 sends the station brag tape (rig message) or the contents of program lines 360 and 361. These linked lines are explained in F1 above. When linking program lines to allow more than the standard line lengths, caution should be exercised on the unexpanded VIC-20, as memory limits can be approached quickly and result in erratic code spacing. Should this happen, abbreviate your messages or add memory expansion.

F7 toggles between Compose and Send modes. When Compose is chosen by a single depression of the F7 key, 73 Morse R/T will allow building your transmission in advance of being sent. It will not function during Receive. Function keys may be embedded during Compose, but remember that the lengths of messages linked in this manner will affect the maximum count of 255 characters. It is easy to exceed maximum buffer lengths unexpectedly in this way. Should an error develop due to this, type GOTO 50 and your transmission will continue with the offending characters removed. Depressing F7 a second time will send your Composed text.

C-64 modifications to 73 Morse R/T listing.

F8 sends "DE (your call)". Useful for IDs and QSK.

Note in line 340 (and others) the buffer (B$) is added to the message, preventing the contents of the buffer from being lost. This enables the messages to be used within text in either the Direct or Compose modes. In the Compose mode only, a reversed number representative of the inserted Function Key will appear within text. Although not represented in Send, the Function Key will be transmitted.

Receive

With a suitable interface connected, Receive may be entered by depressing the back-arrow (escape) key. A second push of the same key returns to the Transmit mode, and in this way the key toggles between modes. The back-arrow key may also be implanted in text. When encountered, the modes will change.

The simplicity of the receive circuitry on the accompanying schematic is roughly representative of the function refinements. Although accurate and flexible, these restrictions suggest several actions to ensure optimum results.

The variable resistor is used to adjust the loop frequency. Loop adjustment should coincide with the center frequency of the CW filtering engaged. For example, a 750-Hz (typical) filter would require your interface loop be adjusted to 750 Hz—the idea being to adjust the LED to brilliance with full filtering engaged.

As a digital device, the VIC requires spaces of silence between Morse characters for recognition. Therefore, rf gain should be adjusted to permit the LED to extinguish between keying. In other words, tune in the desired signal and reduce rf gain to a point where QRM does not keep the LED from blinking. A threshold adjustment (squelch) would be helpful here, but is not within the scope of this article.

Any suitable interface can be driven with 73 Morse Receive/Transmit. The prerequisite is that the interface in use is TTL-compatible and goes low on keying applied to the external DEMOD input on the interface included here.

Although there is an upper limit to receive copy speed, we have successfully decoded 30-word-per-minute CW generated by HAMTEXT and MBATEXT with this program—admirable for Basic. We feel VIC-20 and C-64 Basic has been optimized at this point. Morse transmission at speeds in excess of 65 wpm is possible and has been decoded by the previously mentioned commercial programs. At speeds approaching 80 wpm, 73 Morse R/T is detected with excess spaces but remains readable.

It is important to mention that no CW decoder will copy poorly sent CW. If, for instance, the transmitting station sends a question mark as "IZ", then "IZ" will be displayed.

In view of this restriction to accuracy inherent in all time-based microprocessors, we recommend you remain faithful to your own receiving speeds and not dive into a speedy QSO you can't keep up with should your VIC crash. If you parallel a key alongside the computer, you can always request QRS if your program or VIC crashes in mid-QSO and you find yourself adrift without oars.

Circuit Notes

The transmit section of 73 Morse Receive/Transmit utilizes the CB2 (RS-232 Sout) signal at the User I/O port on the VIC-20 and -64. CB2 will go low when the transmitter is to be keyed. This further enables the Run/Stop/Restore sequence to interrupt keying at any time and prevents the computer from keying the transmitter on power-up initialization or Reset.

For Receive, this program makes use of the PB0 signal at pin C and the CB1 signal (RS-232 Sin) at pin B. PB0 must go high when a received signal is detected. Although CB1 is not used, it is connected in anticipation of the later addition of RTTY and ASCII upgrades.

The 567 tone-decoder IC is available at most parts stores and is common.

A 12/24 .156 spacing connector is required for this interface. Lacking one, a 22/44 pin connector (common) can be cut to fit. The interface may be constructed on a piece of perforated board and the underside of the connector attached to the board with strong (two-part) epoxy. Refer to the manual furnished with your computer for pinouts.

Do not attempt to key a rig which presents more than +30 V or *any* negative voltage at the key terminals with the direct keying portion of this circuit, for damage to your computer will likely result. Provision for total isolation of the type necessary to permit safely keying such transmitters can be made through a common reed relay using the alternate keying section of the schematic.

Acknowledgements

The authors of this program would like to acknowledge conceptual assistance from Jim Thomas W9OAG, whose application of the 567 tone-decoder circuit appeared on an interface card for CW split-screen on the ZX-81 and was used by permission. Additional thanks to Cliff Nunnery NU4V from whom the ZX-81 program and interface are available. Automatic receive-timing adjustments used in this program were based on the equations of J. C. Sprott W9AV, who created them for the TRS-80 computer.

Notes

If in testing this program you notice scrambled CW, look for an added or missing comma in the Data statements of lines 500 through 540.

Users of the Commodore-64 should replace any existing program lines in the VIC version with those appearing in the 64 modification listing, adding those not shown in the VIC listing.

This program previously appeared as J/20 Morse R/T in the bi-weekly *Journal/20* and has been in use for over a year. It is in the public domain. ■

Piggy-Bank Repeater Project

Set it and forget it.
This inflexible controller doesn't bend the budget.

I know what you're thinking. The last thing this world needs is another repeater control, right? (Some would say the last thing we need is another repeater, period, but that's another matter altogether.)

The past few years have seen a proliferation of microprocessor-based repeater controls offered for sale in *73, HR, QST,* and other magazines. While it's certainly true that these units do offer an amazing array of functions, bells, whistles, and the like, it can be said that such systems may be far more than the average repeater operator needs for simplicity and reliability.

The circuit described here won't win any engineering awards but won't break your bank, either. What's more, all of the parts can be obtained easily. The emphasis is on "set-and-forget" operation, so there are a minimum number of functions to fuss with when performing the final installation. Best of all, this circuit lends itself well to modular designs, such as plug-in cards. In this particular case, this meant the end of the wonderful January trips to the repeater site to troubleshoot in minus 10° weather.

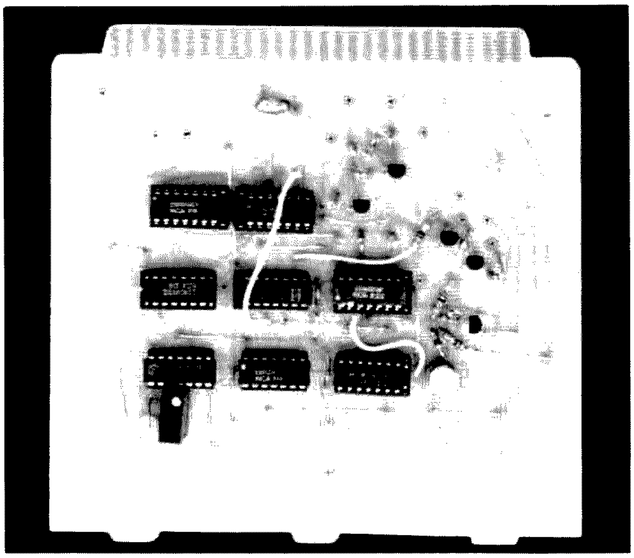

Photo A. Completed board minus the LEDs.

The Split Rock ARA repeater in Rockaway, New Jersey, had used for many years a circuit based on first-generation TTL devices. When it was first built in 1972, it was a pretty impressive piece of equipment! This controller featured a 1.5-second delayed key-up, a diode-matrix ID generator, a "polite" identifier, and used only 22 ICs, 30 diodes, 3 relays, and numerous transistors to do the job. It was constructed on plug-in wire-wrap boards (presumably to allow for some experimentation) and then the wire-wrap was soldered. With attendant power supply, it took up about 12" by 4" by 6"—not a small package.

Well, time marched on. Pretty soon, chips began to fail about the time that various pieces of circuit documentation were mysteriously vanishing. The identifier began cutting itself off in mid-ID, giving us one of the world's shortest calls, "DE W—". Worst of all, the delayed key-up began resetting on every call, resulting in more "doubles" and "triples" than the World Series!

What to do? The repeater users were ready to march on Washington. Everyone grumbled about the situation. The most popular question at our monthly meetings (after "when do we adjourn?") became, "Hey, when are you gonna fix the ID box?? Hunnhh?"

With visions of a lynch mob firmly in mind, the decision was made to deep-six the old control package in nearby White Meadow Lake and redesign a brand-spanking-new controller. Thus would our repeater move into the 80s!

I had experimented with many Rube Goldberg devices over the years for repeater control, being first attracted to a design using 555 timers. No good! The 555 is surely the most versatile IC ever to grace this earth, but it suffers from a problem common to most one-shots: poor noise immunity. My first attempt at a circuit of this type worked great on the bench, but soon wound up in the garbage, as those poor 555s keyed up on every spike within a mile of our site. Sure looked good on paper, though...

A circuit using flip-flops and unijunction transistors soon made an appearance in the March, 1979, *QST,*[1]

and it looked promising. The user "set" the flip-flop upon key-up, and the UJTs "reset" the flip-flop using the classic RC circuit to determine squelch-tail time. Again, not a bad idea on paper. However, in the repeater, it was soon discovered that the user got erratic squelch tails, if any tail was generated at all!

Using tantalum capacitors and precision resistors didn't cure the problem. RFI and timing problems put this model in the circular file. Back to the drawing board! Although the circuit was a clever design, the fact that the capacitor did not always charge completely on each transmission (especially during a series of rapid QSOs) led me away from using any RC-type delay circuits for future designs.

The problem was just too many variables, such as the quality of electrolytics used, type of UJT used, grade of other transistors, and questionable response in extreme environments. However, the basic concept was halfway there—using flip-flop logic and toggling between set and reset modes. Ah-ha! Now I was getting somewhere, and after studying schematics for the 10,000th time, it occurred to me that a better way would be to use clock pulses to do the job. This meant an onboard clock and appropriate divide-by-X chips. And so was born the final circuit (although more out of desperation than inspiration!).

Refer to Fig. 1 for the schematic. Q1 and Q2 serve to isolate any COR lines from the CMOS logic, as well as provide high enough signal levels for reliable keying action. Either positive- or negative-type COR lines can be used, swinging typically from .5 to 8 volts, or vice-versa. U1, a CD4047 free-running multivibrator, serves as the on-board clock. It is set to about 120 Hz at pin 10. The output from U1 drives U2, a CD4040 ripple counter. These two chips make up the heart of the timing circuit and are never disabled while the circuit has power to it. The clock pulses from U2 are fed to three on-board divide-by-seven chips, U3, U4, and U6, which are all CD4024 types and which generate the delayed key-up, squelch tails, and timeout intervals, respectively.

U4 serves an additional function: It resets the delay line after 10 to 12 seconds of inactivity. Or, if you prefer, it can be disabled. When the user opens the squelch on the repeater receiver, the ensuing COR voltage change (either high-low or low-high) will cause Q1 to go low, which in turn also sets pin 2 of U3 low. This COR signal is also sent to pin 12 of U5A, a CD4001 quad 2-input NOR gate. U3 is now counting clock pulses, and after 1.5 seconds, pin 11 of U3 goes high, setting U7A, a CD4013 dual-D flip-flop. Pin 2 of U7A, the $\overline{Q}$ output, goes low. This signal is sent to the other input of U5A, pin 13. Now we're ready for action.

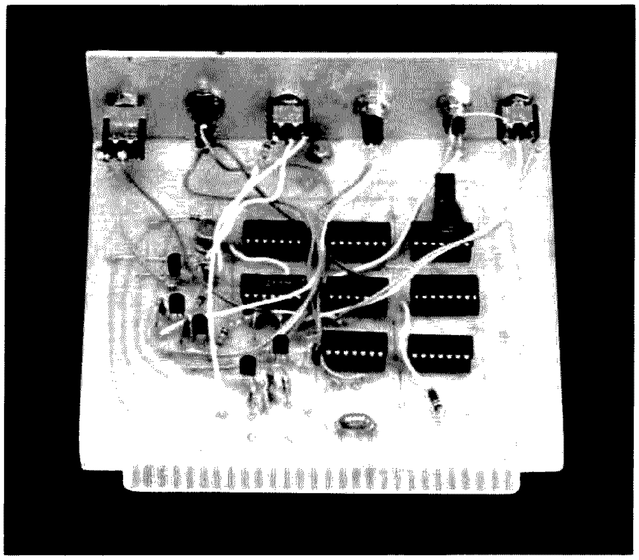

Photo B. Controller built on plug-in card.

U5A at this point goes high through pin 11. This line sets U7B through pin 8, causing pin 12 of U7B to go low. This logic is sent to pin 6 on U5C. Pin 5 is normally set low (we'll get back to it in a moment), with the result that the output of U5C, pin 4, goes high and keys the transmitter through relay driver Q5. When the input signal is released, pin 2 of U4 is set low via NOR gate U5B and after 2.5–3 seconds, pin 11 goes high, resetting U7B through pin 10. This is the squelch-tail circuit. If no further activity is detected after 10–12 seconds, pin 5 of U4 goes high and resets U7A through pin 10. The delay line is back on and ready for the next user(s).

This may seem like a fair amount of work just to kerchunk the old machine, but you'll always get a consistent squelch tail, each time and every time. You turn on

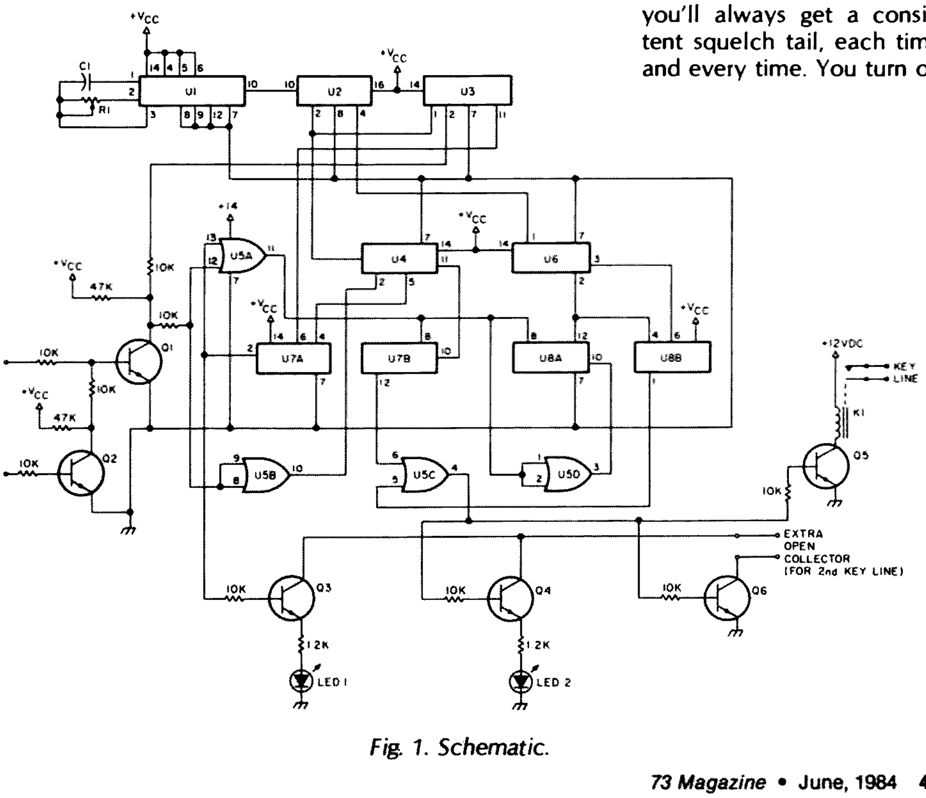

Fig. 1. Schematic.

the various flip-flops and the on-board clock, and counters turn them off, keying the transmitter and dropping it in the process. No noise spikes to fool one-shots, no variable-length tails, timeouts, or delays. Sound good?

Read on! Now you'll find out why I sent you through all those gates and flip-flops. Refer to pin 5 of U5C, the key-line driver. By using a NOR gate here, we've incorporated timeout control, merely by driving pin 5 high. Stops 'em every time! This is easily done by using two more flip-flops—U8A and B.

Let's assume someone has brought up the repeater and is chewing everyone's ear off describing the new Ultra-5000 computerized rig. Remember the COR set conditions: U3 is enabled, U4 is disabled, and U7A and B are in the set mode. Refer again to the schematic and you'll spot U6, another divide-by-seven counter. When pin 11 of U5A goes high, it sets pin 2 of U6 low, enabling the counter. U6 derives its clock pulses from pin 4 of U2 for determining the timeout interval. The Split Rock repeater always had about a 90-second timer, so this program was retained.

As long as pin 2 of U6 is held low, which it is whenever there is activity on the receiver, it will continue to count up to 90 seconds, at which point pin 3 of U6 goes high and sets U8B through pin 6. Pin 1 of U8B then goes high and is sent to—you guessed it—pin 5 of U5C. Pin 4 of U5C goes low and the key line is dropped, shutting off the repeater.

When our hero runs out of superlatives on his new toy and drops the input carrier, several things happen. First, U3 and U6 are immediately reset. U4 is now enabled and its pin 11 goes high, resetting U8A and setting pin 12 high. Like a stack of falling dominoes, this resets U8B, which then resets pin 5 of U5C low, and we're back on the air. You'll get the customary squelch tail, and that's it! Everything is ready for another timeout.

The timeout timer can be reset immediately upon the dropping of each input carrier by using pin 11 of U4, or, if you prefer a short interval for the "beep," pin 9. This will give about a 1-1.5-second interval for reset. The

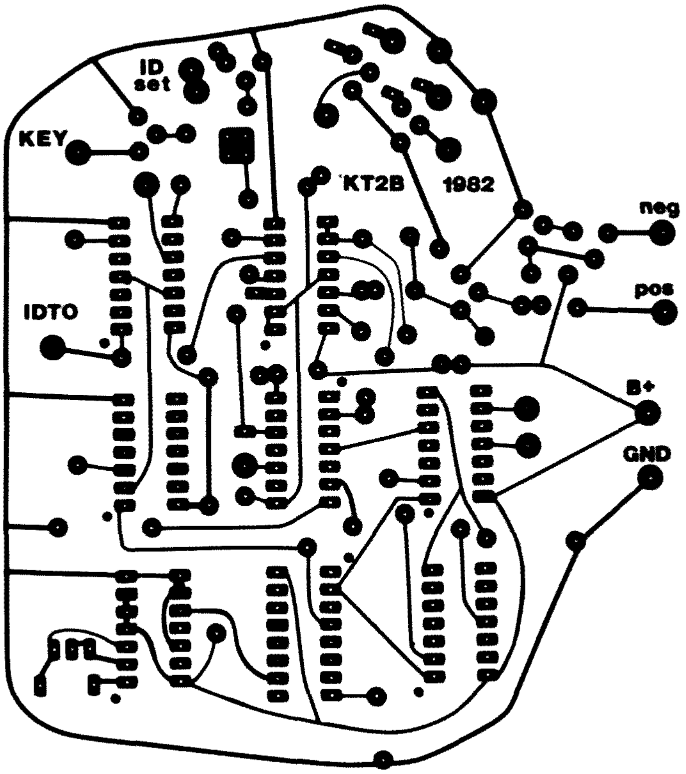

Fig. 2. Printed circuit board.

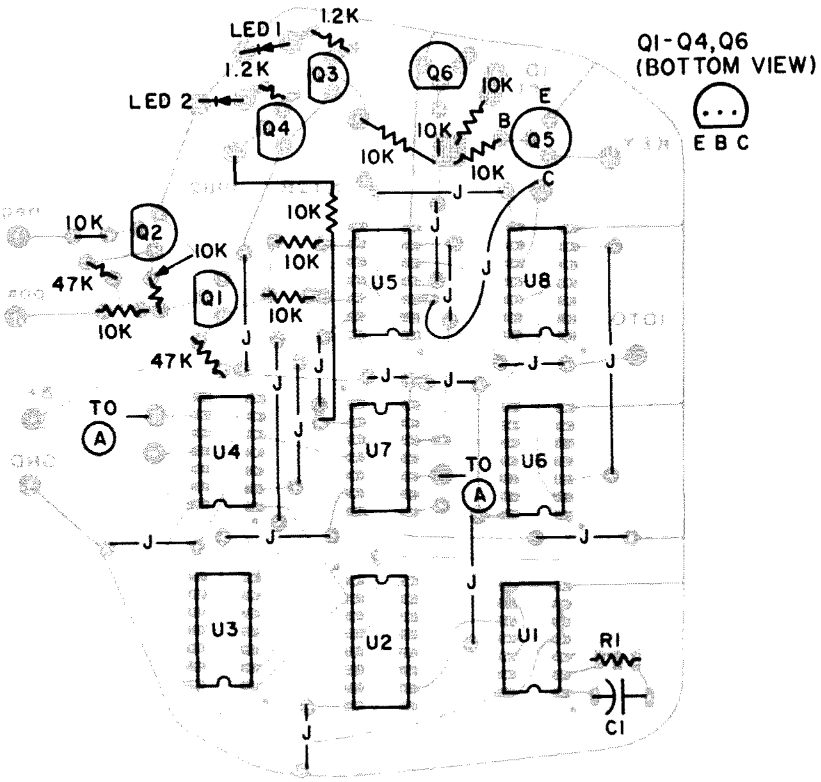

Fig. 3. Component layout.

high-going pulse from pin 9 can be used to activate a beeper, if needed. The time-out program can be changed to the legal limit of 180 seconds by taking clock pulses from pin 13 of U2 and sending them to pin 1 of U6.

That's all there is to it! The addition of a couple of LEDs to indicate DELAY and COR status puts you in business. Photo A shows a completed board minus LEDs, while Photo B shows one version built on a WESCOMM 56-pin plug-in card which SARA uses on K2RF/R. Two built-up boards are now in existence, which means anytime there's a failure, on-site maintenance consists of pulling the bad board and plugging in a new one. The defective unit can be repaired at your leisure in a nice warm place, not some icebox on a hilltop. Photo C shows the difference in size between the old controller and the new version. Fig. 2 shows the circuit board used, and Fig. 3 shows the component layout. If there is sufficient interest, high-quality printed circuit boards will be made available.

One final suggestion: Use good chips. You're trusting the control of your machine to this little bugger, and seconds or grab-bag ICs just won't hack it. A good source for chips would be Jameco Electronics.[2] If you aren't sure if it'll work under harsh conditions, do what I did: Place the board in a plastic bag and toss it in the freezer for about two hours, then pull it out, plug it in, and get the good (or bad) news. Prime chips should handle this test with no sweat.

There is no place to attach the relay to the circuit board since every relay is different. So, do what I've done and glue your relay right to the board on its side—there's plenty of room. Don't forget to bypass the coil with a diode or you may have some problems with spikes.

It's not a whiz-bang micro-based control with 3,000 functions, but on the other hand, you ought to be able to build one of these for under $25.00 with all new parts, and that's a worst-case guess. This unit is ideal for hard-to-get-at locations or for remote links. You can add any type of ID circuit you like; just use the output of pin 11 of U5A to trigger it, through an appropriate transistor.

Have fun! If any questions arise in construction, send along the usual SASE and I'll try to help. ■

Not-So-Famous Garriott Words

In one of his first post-STS-9 appearances, W5LFL spoke at Foothill (CA) College. We record his dedication to amateur radio.

Last February, Dr. Owen Garriott W5LFL described his historic space-shuttle operations in a speech given to over a hundred hams at Foothill College in Los Altos Hills, California. Owen was in the Bay Area to address engineering faculty and students at Stanford University, his alma mater. His appearance at Foothill was arranged by Ted Harris N6IIU, Disaster Services Director for the Palo Alto (California) Red Cross.

Before Owen spoke, college trustee Robert Smithwick W6JZU noted how appropriate it was that the first ham to operate from space should address a group at Foothill, because the college was the original home base for Project OSCAR. Dr. Smithwick also reminisced about the beginning of the space age in October of 1957.

The following is an edited transcript of Dr. Garriott's talk.

Smitty mentioned the events that occurred October 4, 1957. I well remember where I was on that evening. I was a graduate student here at Stanford University, just in the process of looking for some interesting dissertation subject, when all of a sudden the Russians were kind enough to provide the ideal opportunity with this beeping satellite putting out its beeps on 20 and 40 MHz.

On that Friday evening, we went out to the radio-propagation field site (along with a good many other hams) and listened to the sputnik beep its way around the Earth, all of us of course amazed.

The field site was pretty well equipped: We had a number of chart recorders and different kinds of antennas there because the field site at that time was being used for studies of propagation effects. Therefore, we could connect up the output of the Collins receivers to the chart recorders and look at the amplitude and also the very interesting fading pattern, which of course was quite different than any kind of fading that had ever been observed on normal 20-MHz propagation paths.

I can remember the question being asked, "Well, that's puzzling: Why is that fading coming along here at something like a one- or half-a-Hertz rate?" The person who asked was Professor Ron Bracewell, and I suspect he knew the answer to the question at the time he asked. But the question was asked to get us graduate students thinking about it.

Well, that fading, as you all probably already know, turned out to be the Faraday rotation of the satellite signals. As a signal travels down, as it propagates through the ionosphere, its polarization is rotated and that produces the fading pattern which we see on the ground. It was very fortunate for me, as that turned into a dissertation topic in the next year or so.

So I very well remember what happened that October, and it certainly was a very exciting time, that evening as well as for the next year or two, as we began to understand something more about how radio signals propagate through the ionosphere.

Spacelab Constraints

Well, we could go on with some of the historical stuff, I think, for most of the afternoon. There's an awful lot of interest associated with it. But let me talk about events of more recent history, like in the last couple of months. That is, specifically, what we were able to do on Spacelab.

We were on duty for 12 hours a day, and my ham activities were very carefully constrained to make sure that they did not interfere with any of our basic mission objectives. I had a list of 12 items which could not be violated in terms of the ham operations, including such constraints as no more than an hour a day, never when I was on duty, and all these kinds of things. And as a matter of fact, there was no infringement of the main objectives of the flight. We did accomplish all of the scientific activities that we were scheduled to do—and more, in many cases—and I still managed to find a little bit of time for the ham activities in the off-duty periods.

STS-9 Equipment

Now, some of you have perhaps already gotten the February *QST*, so you've seen a picture of the little hand-held transceiver that was used for the in-flight communications. I'll just mention a little bit about some of its characteristics. It was essentially a Motorola design, but it was built by individual Motorola employees during their off-duty time. It may have been a little bit modified from their standard design; I don't really know.

The radiated power was only 4 Watts, but in spite of that, the signal-to-noise calculations showed very good margins. I know the people here at San Jose City College had perhaps as good a calibration as any, and I think your numbers were something like 40 to 43 dB signal-to-noise ratio. And certainly when we were in an attitude in which the antenna was pointed toward the Earth, people could hear from horizon to horizon with an excellent signal-to-noise ratio.

The antenna that we used was also built by hams, these at the Johnson Space Center Amateur Radio Club. It was their own design. It was essentially a single split ring, and then the feedpoint was adjusted around that

split ring until the impedance was matched to the 50-Ohm coax. The measured swr before the flight was 1.2 or 1.3, something like that —really quite good.

The antenna was mounted in a little dish about five or six inches deep and put in the overhead window in the aft flight-deck area, right behind the cockpit area. It worked extremely well. I don't know what the real swr in flight was—I didn't have a meter—but it must have been very close to what we had measured prior to flight on the ground, because the performance as near as we could tell was absolutely nominal and gave very good results.

I had to take the antenna down after every operation, because it really filled up one of these overhead windows and the other crew members preferred to have the opportunity to look out instead of at the back of this metal dish. And so, after each pass on which I was using it, I took it down and sort of taped it over to a side wall where it was out of the way. And then I just took a few minutes to put it right back up in the overhead window again when the next opportunity came along.

U. S. Passes

We had publicized, as I expect most of you know, what the most favorable opportunities would be. We indicated that not all of those listed would be possible in flight, and that's the way it turned out. But still, most of my operations were among those that were listed in the pre-flight forecasts.

We got an extra day extended to the flight, and of course we had no predictions for those, but a lot of the good hamming opportunities came in just the last two or three days of the mission. By that time, I think people pretty well knew how to use the orbital elements that were transmitted by the ARRL, and I suspect most of you knew pretty well when the spacecraft would be coming over, because certainly it sounded as though there were plenty of people on the ground who knew when to transmit.

Dr. Owen Garriott W5LFL speaks at Foothill College about his STS-9 amateur-radio activities. (Photo by Jim Koski KT6W)

One of the most interesting passes came right down across the Mississippi Valley on either the last or next-to-last day in orbit. I've had reports from people on both the east and west coasts who were able to hear those transmissions. In this case, the antenna was pointed right down toward the Earth, and signals were received well beyond the actual geometric horizon. Probably some refraction in the ionosphere, a little bit of refraction around the limb of the Earth, would account for the fact that the signals were really heard over a substantially larger distance than a geometric straight-line path.

It also turned out that even when the antenna was pointed toward the sky, there was enough of a side lobe around the edges of the vehicle that some transmissions could be heard on the ground, and vice versa, although of course signal levels were very much lower than when the antenna was pointed in an optimal direction.

Special QSOs

A number of special contacts were established. For example, I talked with my home ham club in Enid, Oklahoma, W5 Hot Tea Kettle, where I started when I was a teenager. My mother was at the shack, so I had a few moments to exchange a greeting with her. And on the same pass, headed toward the southwest, we passed over the Johnson Space Center where my sons were at the local ham club. So it provided an opportunity to exchange a few words with them.

I think most everyone knows that Senator Barry Goldwater has been very important to our ham activities by supporting ham interests in Congress. I had a special opportunity to talk with him for a few seconds passing down the east coast. And also, very fortunately, I talked with W1AW. They were competing right along with everybody else and managed to show up on one of the published frequencies.

King Hussein was another interesting brief conversation. Of course, there's not a lot of competing activity flying over the Near East, so I didn't have too much trouble having a very nice brief conversation with him.

Shuttle Communications

One final contact I want to mention came when we were flying over Australia. One of our astronaut personnel, Dr. Joe Kerwin, is on assignment in Australia near the NASA tracking station at Canberra. We talked with the hams there, and they went out and set up a fairly high-gain antenna at one of their tracking locations—it's still ham gear, however—and I prearranged a time and frequency to meet with them.

We had it arranged that I'd set up the communication via the ham link, but then they would patch me in via their federally-leased telephone lines back to the capcom [capsule communicator] in Houston. So I talked to Joe briefly and to all the hams at that station, and then they patched me in to the federal line and I talked to the capcom, who was communicating with the spacecraft via the normal channels from the control center in Houston. And the quality of that transmission was better than the normal Ku-band transmissions. It very much impressed the other members of the flight crew and the flight commander, John Young.

John is also the head of the Astronaut Office, and I think there really is a genuine interest in the possibility of having something like this available for a backup communications mode in the future. Whether or not anything develops from that, I don't know. But I think his interest is significant, and others in the NASA administration have also mentioned that to me.

Advantages of 2 Meters

I think 2 meters was a good choice for the operation. Some people have asked me since, "Well, shouldn't we go to higher frequencies?" or "Shouldn't we go down to HF and look for more interesting propagation effects?" All those things are interesting to think about, and we might want to consider something different on another occa-

sion. But for this first opportunity, I think 2 meters was exactly the right choice.

First of all, the Doppler shifts are about plus-or-minus 3.5 kHz, and if you can imagine using anything other than an FM receiver—say, single sideband—you'd be continually trying to track and take out that Doppler shift, both on board and on the ground. It would be a terrible job. With all the hundreds of signals being received and everybody having different Doppler shifts, it would be a hopeless task. Working with an FM discriminator, of course, any place you operate along the passband of the center part of that discriminator circuit, it'll take out the Doppler shift for you. So that was an enormous advantage immediately.

And the second thing about an FM circuit is that it also tends to select the strongest signal and suppress the others. That was also extremely important from the practical standpoint of trying to pick out one or two stations from maybe a hundred that were calling on each of the uplink frequencies. So the FM transceiver at 2 meters was really an ideal choice for this first effort.

Future Changes

All in all, it's just hard to imagine how we might have done things much differently, although I do want to make a couple of points about that.

First, you'll see in that picture on *QST* that I was operating with a very lightweight headset, just a little single bar over my head with one earpiece and a little sponge underneath that. This was designed for working in the spacecraft, so that I could hear all the other things going on around me. That was important for using it in a spacecraft environment for other purposes, but it was a difficulty in working with ham equipment. There was too much outside noise. What I really needed was a pair of good headphones that would really isolate me from the outside world.

And then, the only really serious thing, there was no variable adjustment on the squelch circuit in the transceiver. And the squelch circuit operated such that it compared the signal at the center of the band with what it interpreted to be noise coming in from the outer edges of the passband. Well, with plus-or-minus 3.5 kHz, all these other signals coming in provided what the receiver thought was a lot of extra noise in the fringes of the passband. Therefore, it would often decide, "Well, the signal isn't stronger than the sideband noise, therefore I'll turn on the squelch, because it's not a strong signal." And that way, the whole receiver would be deadened, whereas really I had plenty of good signals there, but no opportunity to inhibit the squelch. So that is the one design feature that I'm sure we would change the next time around.

Mission Successful

Outside of that, things went really beyond our expectations. Every objective we set before the flight was achieved during the time I was able to operate. I was on the air for something like four or five hours total, and during that interval, something like 350 two-way contacts were established. And the ARRL has about ten thousand requests for SWL reports. So it was really very widely participated in by both hams and SWLs. It was a marvelous opportunity and a great pleasure for me to have had this chance to operate from space. And I'm just sorry I'm couldn't have had a two-way with every one of you who tried to contact me. ■

Better the R-70

At your own risk, you can soup up one of Icom's super receivers. How to do it was not read here.

Tom Carlson KE4AQ
Box 4716
APO NY 09109

Being an avid SWBC DXer, I have read with interest in many publications the consistently favorable reviews given to the new Icom R-70 HF receiver. I have been SWBC DXing for a period of time using a high-quality portable receiver, but I finally reached the point where I needed to upgrade to another level to snatch some of the weaker stations I sought. With this idea in mind, I recently purchased an IC R-70 and have been having a ball ever since.

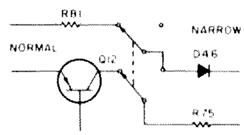

Fig. 1.

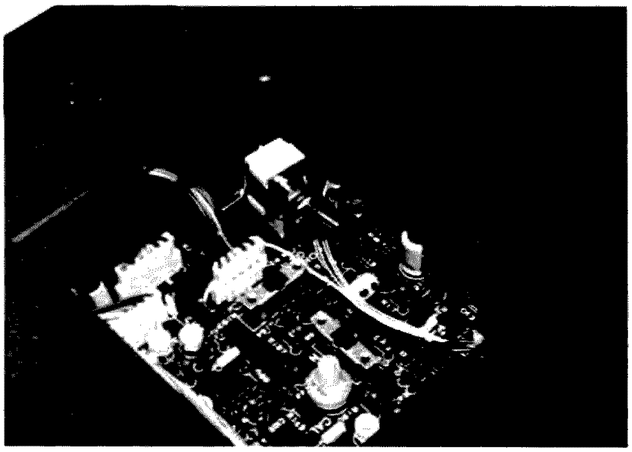
In the AM mode of operation, the passband tuning allows the passband to be varied from 6 kHz to 2.7 kHz. In the SSB mode, the passband can be varied from 2.3 kHz to 500 Hz. This is indeed sufficient for many applications, yet it seems that many of the rarer DX stations that I sought were sandwiched between two or more powerhouse SWBC stations at ± 5 kHz. Needless to say, the resultant cochannel interference would many times render my desired station unintelligible, in spite of the passband tuning.

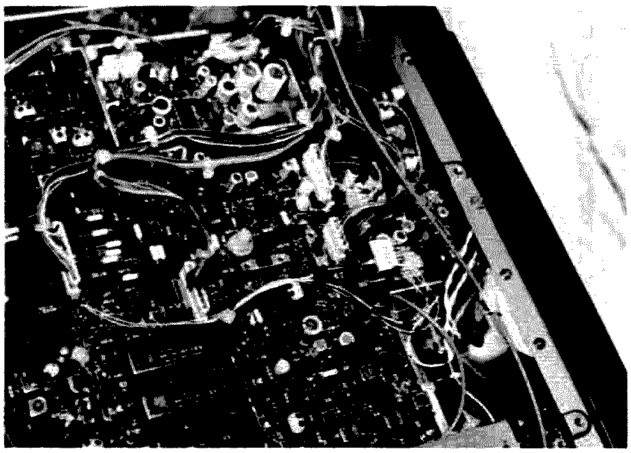
It was at this point that I pulled out the schematic diagram and began investigating the possibility of switching in the narrower-bandwidth ceramic SSB filter instead of the standard ceramic AM filter.

The steps that follow will

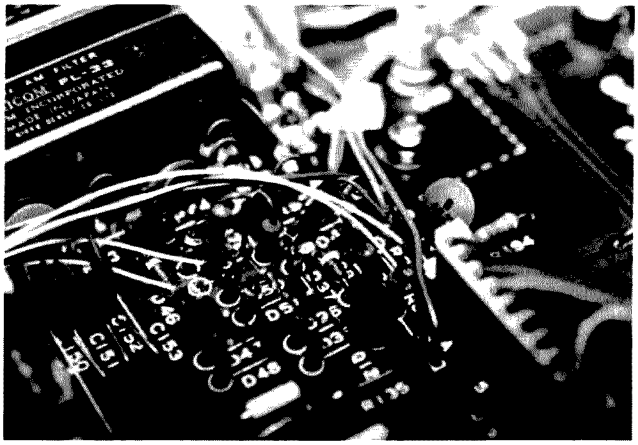
Photos by D. A. Carlson



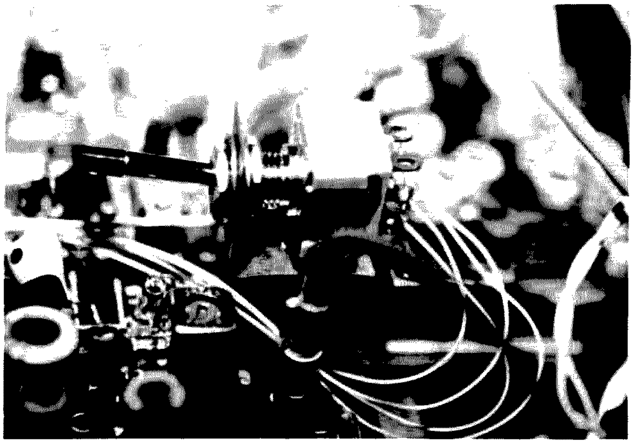
Completed conversion. The switch may be accessed with ease through the top trapdoor.



Routing of wires from the switch to their respective connection points.



Wires connected as per schematic diagram.



Mounting bracket formed from a bent spring clip.

describe the modification of the Icom R-70. At the 3rd i-f of 455 kHz, the SSB filter of 2.3 kHz will be switch-selectable to replace the standard AM 6-kHz filter. While this cut down on the fidelity of music and some voice transmissions, in many cases it dramatically reduced the co-channel interference problem. It allowed me to pull more than a few signals out of the mud. Physically, no components are removed and nothing is done to the receiver that cannot be reversed.

The parts and tools required are:

- 1 DPDT toggle switch (small)—ALCO MTB206N or equivalent
- 2 feet of hook-up wire (20-24 gauge)
- Solder sucker or solder wick
- Needle-nose pliers
- Side cutters and wire strippers
- Phillips screwdriver
- Soldering iron and solder
- Schematic diagram
- Parts layout diagram

1. Remove the 12 screws that attach the top cover to the chassis of the receiver and lift the cover off.

2. Remove the 7 screws that hold the main circuit board in place and lift up the main circuit board. The wiring harnesses connected to the circuit board do not have to be removed.

3. With the parts layout diagram and schematic diagram, locate R81, R75, D46, and Q12 on the main circuit board.

4. Using the solder sucker or solder wick and needle-nose pliers, lift the end of R81 that is soldered into the same foil track that holds the anode of D46.

5. As in step 4, lift the end of R75 that is soldered into the same foil track that holds the collector of Q12.

6. Cut 4 6-inch pieces of hook-up wire. Solder wires to the following points:
(a) the free end of R81
(b) the free end of R75
(c) the hole that formerly held the end of R75
(d) the anode of D46

7. These 4 wires will be soldered to the DPDT switch as shown in Fig. 1. The wires should be routed and dressed neatly to where you elect to mount the switch. The photos will demonstrate one possibility.

I mounted my switch to one of the screws that hold the main circuit board into place. A bracket was formed from a spring clip bent to 90 degrees, a 1/4-inch stand-off spacer, and a long bolt with lock washers. This held everything to the main circuit board and chassis (see photos). Use your imagination on this one and see what you can come up with from your junk box. I am able to access the switch with ease through the trapdoor in the top cover.

In one position, the circuit is in its normal configuration. In the other position, the SSB filter is substituted for the AM filter to greatly improve selectivity. It must be kept in mind that this conversion affects the AM mode only. The switch must be returned to the normal position when other modes are used although no harm will occur if the switch is mistakenly left in the "narrow" position.

This option has proven invaluable on a number of occasions and improves on what is already an exceptional receiver. ■

Elegant Rotating

K9AZG did it right. W4RNL makes it better. For sightless and sighted hams alike, this update to a 1982 article will be revealing.

L. B. Cebik W4RNL
2514 Dereck Drive, Apt. H-1
Knoxville TN 37912

A simple and elegant solution to setting beam headings for both blind and sighted hams is the K9AZG automatic beam aimer (*73,* November, 1982). With a few voltage comparators, transistors, and relays (plus the usual passive and power-supply components), the device controls CDE and similar rotator control boxes so that by setting a single potentiometer, the operator can step back and relax as the beam turns to the desired heading and stops. Sightless hams now have an easy way to determine beam headings reliably, while the sighted ham can use the beam-turning time for tune-up, logging, and other activities.

The original automatic beam aimer used two sections of an LM339 quad voltage comparator to detect the desired change of direction, as shown in Fig. 1. (Fig. 1 is redrawn from the original to show the individual comparators.) Each comparator controls a transistor switch and relay which in turn control the clockwise and counterclockwise switches of the CDE box. Like any good idea, we can improve upon the original and overcome some potential problems. This article describes some improvements which will prevent a few problems that some CDE rotator owners may encounter with the original design.

The Basic Idea

The basic idea behind the

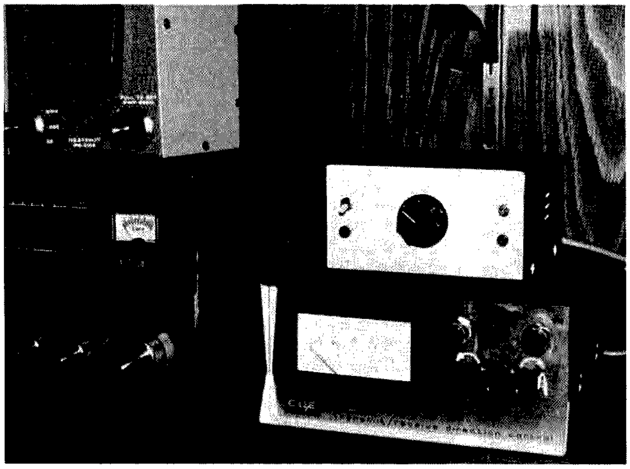

Photo A. The completed beam aimer sits atop the rotator control box at the W4RNL operating position. The ac switch and power LED are to the left and the clockwise and counterclockwise LEDs are to the right. The center knob is the direction control prior to the addition of calibration markings.

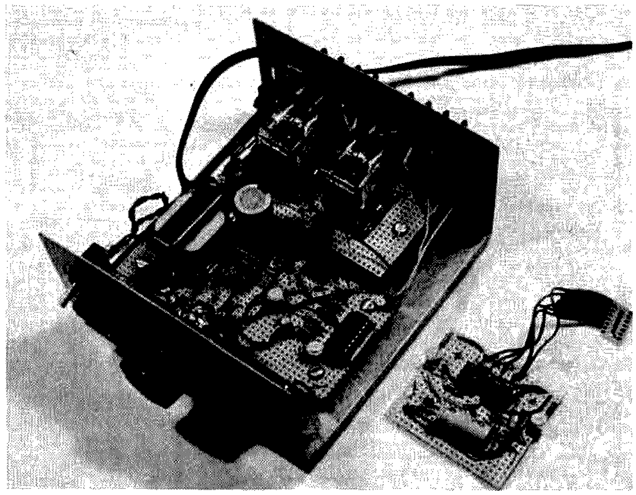

Photo B. An interior view of the quick-fixed beam aimer with the improvement board to the right. The front perfboard contains the power supply and circuitry, while the rear board contains the relays (only two needed for the CD-44).

automatic beam aimer appears in Fig. 2. The 500-Ohm potentiometer in the rotator head changes value with direction, standing at mid-scale when the beam points north and at one of the extremes as the beam points south. Fed by an ungrounded 13-volt supply, the rotating arm creates a ground, thus changing the voltage across the left and right legs of the pot as the beam moves. From extreme point A to center we get a negative voltage; from point B to center we get a positive voltage; and the absolute values of the two add up to 13 volts.

A second potentiometer across the rotator pot (say, about 25k) will read 13 volts across its extremes. More significant for beam aiming, the voltage between the moving arm and ground will be zero when the arm and the rotator pot arm are equal percentages away from the same extreme point. If the beam points north and the second pot is mid-scale, the voltage at the second pot arm will be zero. If we move the second pot counterclockwise, leaving the beam north, we will show a positive voltage. We get a negative voltage if the second pot arm is clockwise with respect to the beam heading. Together, these voltages allow us to turn on one of two relays that close in parallel to the CDE switches, thus activating the rotator. That is the function of the K9AZG circuit.

The maximum voltage that the comparators in Fig. 1 can see is either plus or minus 13 volts. When the antenna is counterclockwise south and we move the second pot arm clockwise to the other extreme, the arm shows −13 volts to ground. In the opposite condition, when the antenna is clockwise south and the pot is fully counterclockwise, the arm shows +13 volts. If both the antenna and the second pot are at either extreme, the pot arm ideally shows zero volts.

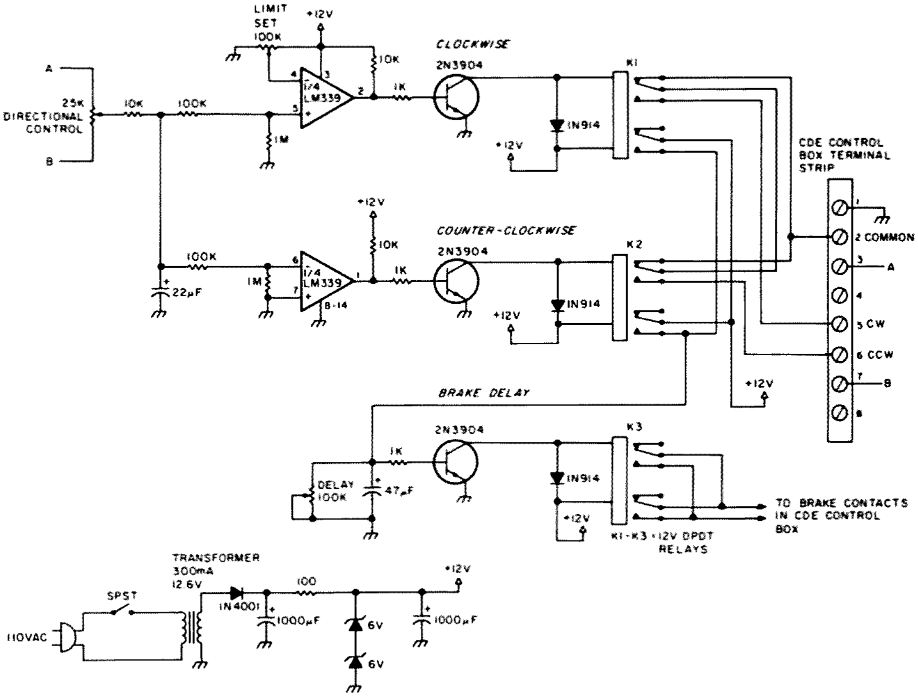

Fig. 1. The original K9AZG automatic beam aimer (redrawn).

Design Limits and Quick Fixes

Unfortunately, only sometimes can we achieve the ideal conditions noted above. There are two design limits to the original beam aimer that may present problems to some hams. First, the CDE rotators have limit switches to shut off either clockwise or counterclockwise rotation at the south heading. Among other functions, the limit switches serve to keep us from wrapping antenna cables like vines around the rotator and mast stub. The limit switches may leave some residual voltage at either end of the scale. Imagine that the limit switches cut off the rotator at positions X and Y in Fig. 2. If the second pot is at its extreme, some small voltage will exist and the relay will not open. K9AZG counters this at one end of the scale with a calibration pot, but the other end of the scale goes to ground.

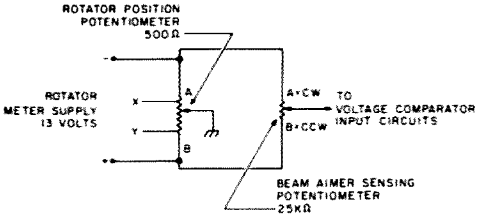

Fig. 2. The basic elements of beam aiming

The quick fix for this problem is the substitution of a low negative-voltage circuit to replace the ground connection of pin 7 of the LM339. Fig. 3 shows a suitable circuit using minimal

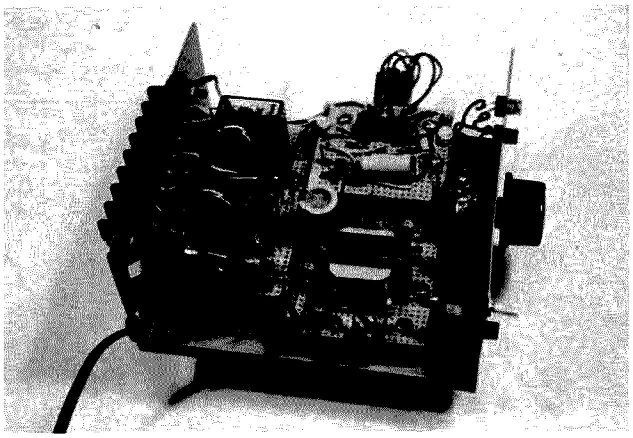

Photo C. An interior view of the improved beam aimer shown from the opposite side of the case. The new input board stands on half-inch pillars over the LM339 socket and transistors. The feedthrough barrier strip for rotator-control-box connections is visible at the rear of the cabinet.

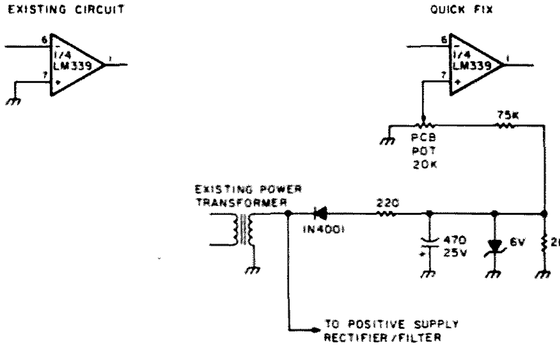

Fig. 3. Eliminating residual negative-voltage effects.

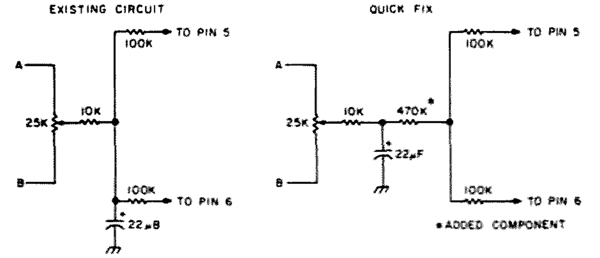

Fig. 4. Input changes to reduce excessive negative voltage.

components. The 20k pot trims the clockwise limit voltage to match the rotator cutoff point.

The second design limit concerns the LM339. This quad voltage comparator is not designed for negative input voltages on either the signal or reference lines. National Semiconductor limits negative excursions to −0.3 volts in their rating sheets. Experiments on half a dozen 339s in the shack showed that between 6 and 8 volts negative input, the comparator would cut off. There was no permanent damage, and the 339 section would come back on when the negative voltage dropped below the limit toward zero.

The effect of this limitation is that when the antenna is fully counterclockwise and the second pot arm goes fully clockwise, the comparator and its relay open up as the second pot passes east (i.e., about −7.5 volts). Thus, a rapid excursion from southwest to southeast might result in nothing happening or might require directional adjustments in small steps.

The quick fix for this design limit is to keep the second pot arm voltage less than the comparator limit. Adding a 470k resistor between the 22-μF capacitor and the branching 100k resistors to the comparator inputs, as shown in Fig. 4, will keep the maximum voltage below 7. The beam aimer becomes a bit less sensitive since now each volt represents around 50 degrees of rotation rather than 28 degrees. However, control is positive, and precision remains quite adequate.

For those hams using the CD-44 and similar rotators, the third relay in the K9AZG design is unnecessary since there is no separate brake-solenoid circuit to control and no required delay between the direction switch and brake-switch release. To discover whether your rotator requires the third relay, check the rotator schematic in the operator's manual. If pin 2 in the rotator is not connected to a brake circuit, then the unit uses an automatically-engaging disc brake. For this class of rotator, the extra relay contacts in the clockwise and counterclockwise switch relays may be connected in parallel and used to control directly the "brake" switch, which actually is a master ac switch for the rotator. Use K9AZG's precautions of bringing the ac to a female socket on the CDE control box rear panel and then to the beam-aimer cabinet.

Fig. 5 shows all the modifications combined in a unit that works well with the CD-44 rotator. These quick fixes, however, are not the best possible design for the beam aimer.

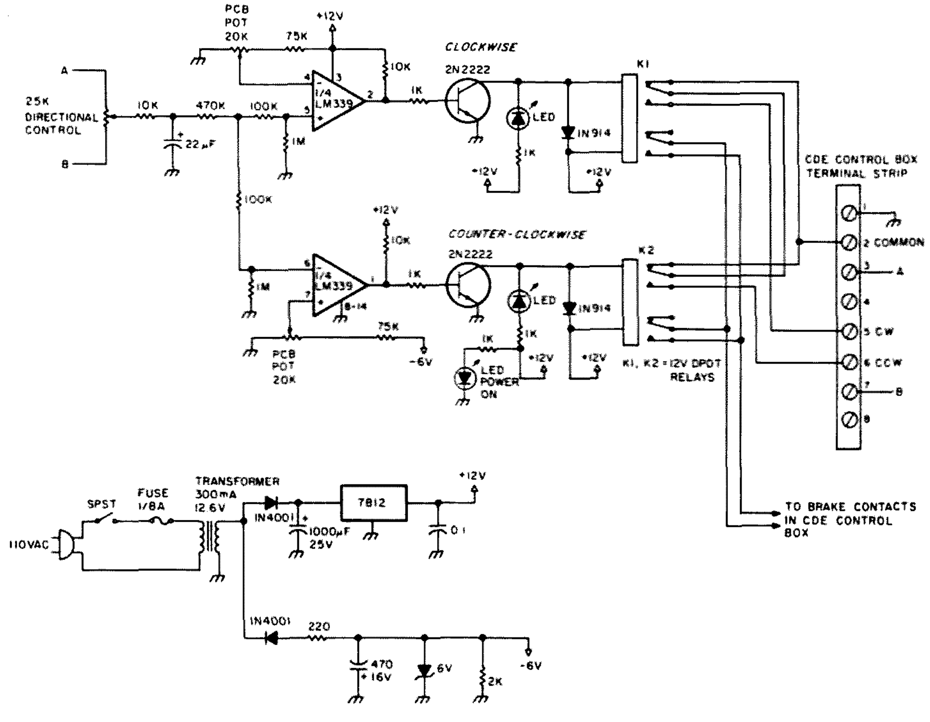

Fig. 5. A simplified beam aimer for the CD-44 and similar rotators.

Improving the Beam-Aimer Design

The automatic beam aimer can be more generally improved by a little redesign. Fig. 6 shows the full set of improvements. First, using LM311s with a dual supply from one 12-volt transformer is simple enough, and it provides for both positive and negative trimming of the voltage-comparator reference lines as well as permitting the 311 to accept a +13- to −13-volt excursion. The uncommitted collector of the 311 output allows for a zero-to-positive output swing to control the switching transistors. This design thus overcomes both limitations of the original.

Second, a slight redesign of the delay circuit for the brake control (which is

needed for larger rotators using brake solenoids) will overcome a further potential problem. The slow decay of the base voltage in the orginal brake-relay circuit can create contact chatter and possible arcing as the coil voltage drops in the transistor-collector circuit. Additionally, the transistor may draw an excessive load while the base voltage drops through the linear range toward cutoff. To create a very positive switching action, we need add only one more LM311, using it to set the delay. Its output switches rapidly, turning the transistor on and off with equal speed. In addition, we can add a variable delay to the 311 circuit and choose a value with the printed-circuit-board pot during initial adjustment.

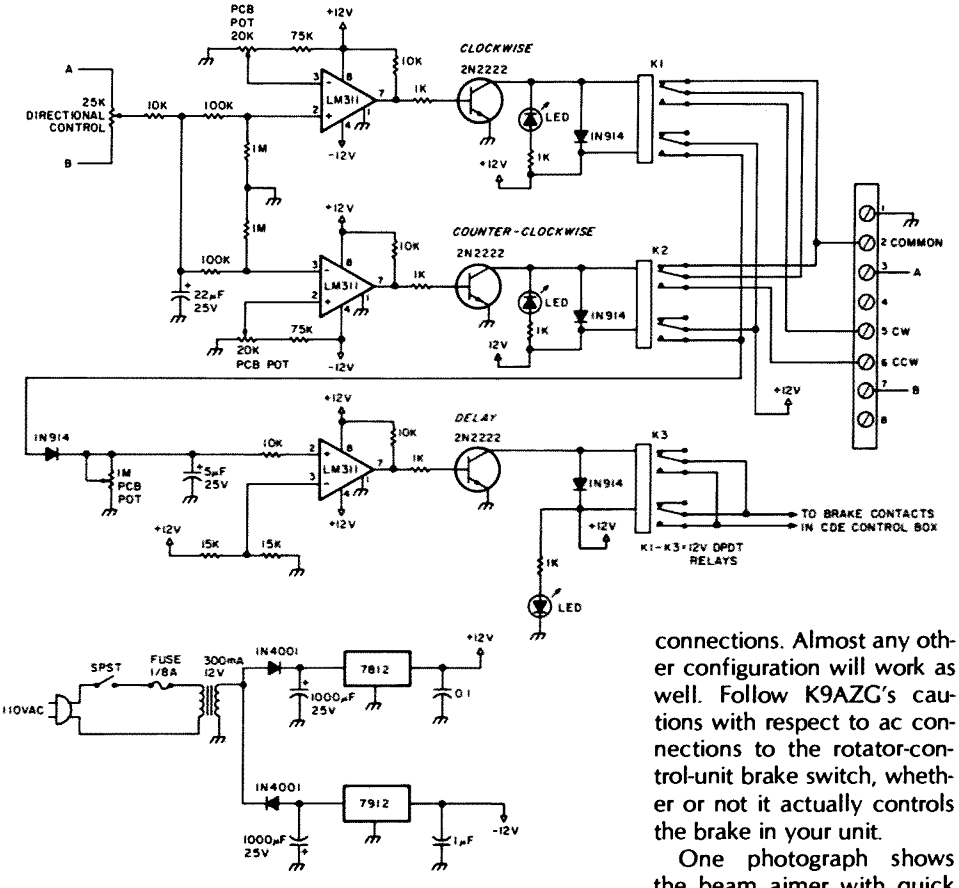

Fig. 6. An improved automatic-beam-aimer design.

Construction

Construction of the beam aimer in any version is straightforward and well covered by K9AZG. Perfboard works well for prototypes, although printed-circuit-board versions would make an excellent club project. The photos show the W4RNL layout. In both photographs, the rear board containing the relays for a CD-44 rotator is mounted a full inch above the case bottom to clear the socket pins. For the CD-44, the delay circuitry was omitted. The forward board containing the power supply and comparator circuit rests on half-inch pillars to ease front-panel connections. Almost any other configuration will work as well. Follow K9AZG's cautions with respect to ac connections to the rotator-control-unit brake switch, whether or not it actually controls the brake in your unit.

One photograph shows the beam aimer with quick fixes prior to modifications for the LM311 comparators. To one side of the LM339 board is the LM311 circuitry board which supplanted the quick-fix version of the aimer in the case. The new

Total estimated cost with new parts: $25 to $35.

board contains its own negative regulator, replacing the low-voltage zener used in the quick-fix versions, as well as the 311 comparators and new input resistors. Removing the IC from the original version permitted easy substitution of the improved circuit. Except for a power lead to the negative supply and an input lead from the direction potentiometer, all other connections go through a DIP cable and plug into the vacated LM339 socket. As the second interior photo shows, the new board mounts above the 339 socket and transistors on half-inch pillars. The increased sensitivity to small knob rotations, with preservation of all of the quick-fix benefits, made the installation well worth the effort.

The mode of construction illustrated in the photographs resulted from continuing experimentation with the circuitry. I do not recommend it except as an example of how noncritical dc circuits are with respect to layout. Any convenient layout will do, including possible installations inside the CDE rotator cabinet.

These design improvements are slight overall but they may serve to keep a first-time builder from growing discouraged in the process of trying the automatic beam aimer. Without knowing where to look for clues, the source of anomalies can be frustrating. However, K9AZG's basic idea is both sound and elegant in its simplicity. So too were his motives. If you know a sightless ham who needs a better way to control his or her beam direction, follow K9AZG's lead and build a version of the automatic beam aimer. The satisfaction of helping a fellow ham get additional fun out of operating will more than repay the small investment in easily-available components. ■

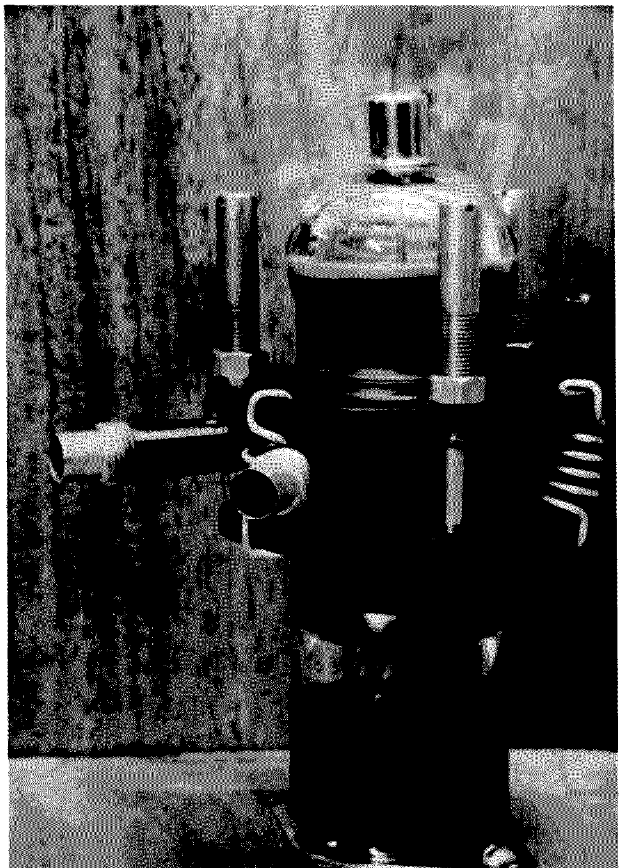
Requiem for the Tube

This pleasing project is perfect for pentodes. It could be the last time you use them.

Around the shacks of most amateurs, one easily can find numerous antique oddball electron tubes. Most of them are too small to be made into lamps and too large for a tie clasp. But still, you want to dig out of those shoe boxes those nostalgic reminders of the good old days and do something with them which is both functional and attractive. Combining the beauty of nature's wood with the glass and metal of

High-power pentode.



Klystron.

"Family scene."

man in the form of bookends is a good example which should please even the most discerning XYL.

First, you need to visit your local lumber yard to purchase six-inch by one-inch-thick shelving. (Even though it is called 1", it measures only ¾" thick.) The material is then cut into two 6½" and two 4½" lengths. Then, using a bandsaw and chisel, a blind dovetail mortise is formed as shown in Fig. 1. Note that the dovetail is only ½" deep so that it doesn't even appear on the inside of the bookend. Each piece is then sanded, and holes are drilled for the tube sockets. The two pairs of wood pieces are then glued and nailed together before applying stain and varnish.

Next, a plate is attached to the bottom of the bookend using contact cement. This plate, which keeps the bookend from sliding, can be made of thin aluminum or wood veneer.

Finally, the tube sockets are screwed down into the drilled holes. For some large tubes such as the 4-400A variety, one might simply drill the 5 holes for the tube pins and then glue the tube in place.

There are several good candidates for old tubes: medium-power transmitting tubes such as the 4-125A, 1625, 807, and 24G; klystrons such as the 2K25, 2K26, and 417B, which look like miniature robots; lighthouse tubes such as the 2C39, 2C40, and 2C43; and acorn tubes such as the 954 through 959 series. A family

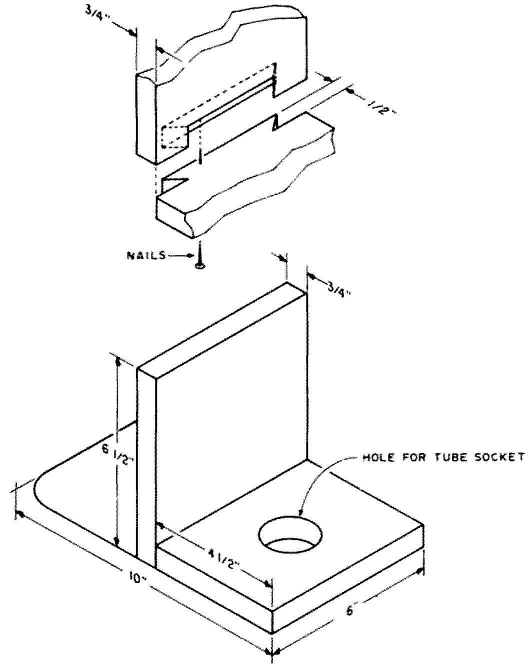


Fig. 1.

scene of tubes with two plate caps was formed on one set of bookends using the RK-34 (father), 2C26 (mother), and HY75A or HY114-B (baby) tubes. ■

New Orders for the R-109

Two bucks and ten minutes are all it takes to re-enlist a vintage receiver.

The R-108, R-109, and R-110 FM Army surplus receivers are readily available, very well constructed, and best of all, inexpensive. They are broadband FM sets covering 20 MHz to 55 MHz, depending on which set is used. These sets can be used with no conversion on 6- or 10-meter FM. They are fully tunable over their full range. I have had good results using them on various projects, including converting an R-109 to SSB for 10-meter use. The sets are very sensitive, using mostly one-volt filament tubes. All of the receivers I obtained came with a 24-volt plug-in power supply (PP-282) which draws about 4 Amps. This is an inconvenient voltage and current for mobile use or fixed operation when only 12 volts at low current is available.

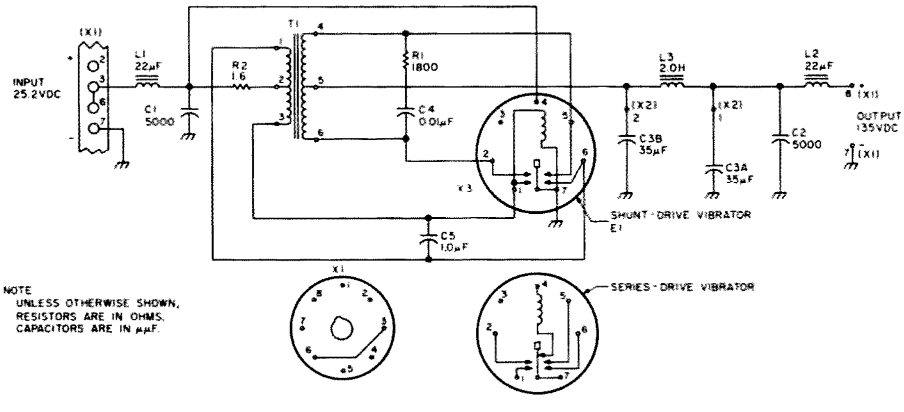

Fig. 1. Original power supply.

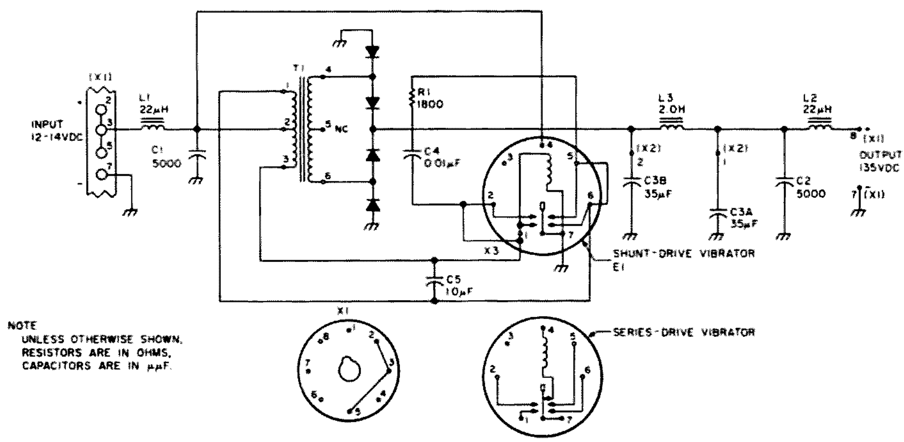

Fig. 2. Power supply modified for 12-14 volts dc.

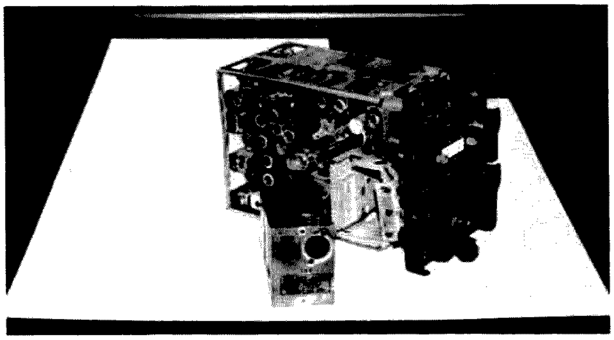
Converting the 24-volt plug-in power supply to 12 volts is easy, quick, and inexpensive. The only part required is a Radio Shack 1-Amp, 400-volt bridge rectifier, catalog number 276–1173, at $1.89. This plus a little solder and wire is all that is needed. After the conversion, the unit draws only 1.5 Amps with 12-14 volts input.

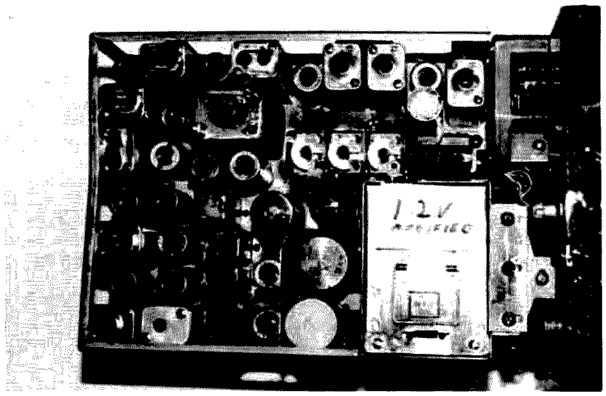
Power supply PP-282 is located in the receiver as a plug-in unit. Remove the receiver from the case by turning the six hand screws 45 degrees, then pulling the receiver out. Loosen the three retaining screws, slide the retaining bar over, and pull out the supply by the wire handle. Remove four screws to gain access to the supply. Two are on the lower back and one each on the top and bottom of the front. The bottom plate is then removed and the upper cover pulled off.

Under-the-chassis changes are covered first. The components are conveniently marked—thank you, US Army. Check each step as you proceed.

1) Solder a wire across the



R-109 10-meter FM receiver with internal power supply PP-282.



Bottom view with the modified power supply in place.

large 1.6-Ohm resistor, R2, shorting it out of the circuit.

2) Disconnect the three wires (2 yellow, 1 red) from terminals 4, 5, and 6 of power transformer T1.

3) Solder the yellow wire formerly on pin 4 of T1 to pin 6 on vibrator socket X3.

4) Solder the yellow wire formerly on pin 6 of T1 to pin 1 on socket X3.

5) Solder the 1-Amp, 400-volt bridge wires marked ac to terminals 4 and 6 on T1.

6) Solder the wire on the rectifier marked − (negative) to ground, pin 7 of socket X3.

7) Solder the red wire formerly on pin 5 of T1 to the + (positive) wire of the rectifer.

8) Turn the supply over and make two changes to power plug X1.

9) Move the bare wire from pin 6 of X1 to pin 5 of X1.

10) Solder a wire from pin 3 of X1 to pin 2 of X1.

11) Reinstall the power-supply cover and base plate and plug the unit into the receiver; tighten the retaining bar screws.

12) In the receiver, be sure that switch S1 is in the 6/12/24-volt position.

13) On the outside of the receiver, install a jumper wire into the Receiver Control plug between pins J and H. Leave the insulation on the center of the jumper because 100 volts lives there.

14) Put the receiver back into the case and apply 12-14 volts dc plus to pin B, negative to ground, pin C, on the power plug. That completes the conversion to 12-14 volts dc.■

Author's note: The power-supply conversion also works with the RT-70 6-meter FM transceiver.

THE LU3ZI SOUTH SHETLAND ISLANDS DXPEDITION

Pushed by the same marvelous impulse, the spirit of radio amateurs, the GACW (CW Argentine Group) sponsored the LU3ZI DXpedition to the South Shetland Islands, following the success of the previous LU7X (1979) and L8D/X (1982) expeditions to the States Islands for the *CQ* Worldwide CW Contest.

Aware of its responsibility, the GACW group operators for such DXpeditions are chosen from among the most reliable and skillful DX men in the group, and the splendid results in former and present DXpeditions show this to have been done, for operating capabilities, techniques, rules, and ethics were respected to the utmost.

An expedition to the Antarctic continent is extremely expensive, but the carefully planned project of Jorge F. Vrsalovich LU7XP was approved by the Direcion Nacional del Antarctico (Antarctic National Management), which rules all activities concerning the Antarctic continent in Argentina—the Instituto Antarctico Argentino (Argentine Antarctic Institute) in charge of all scientific investigations being one of its most important branches.

So, ultra-expensive transportation and logistical help were assured by the Argentine government; other problems were our responsibility!

Alberto LU1DZ started the job to get all that was missing: Oscar Rosity LU5DVO brought a rotator, Jorge Almoyraghi LU1EWL got a 3.5-kW generator from the Air Force, fuel and transportation to the docks were the job of Benjamin C. Cavallin LU9EMB, together with a second, 4.8-kW, generator. A 24-meter tower came from LU8DQ, a 3-element tribander Palombo beam was the contribution of Salvador Palombo LU3FG, and Carlos Rodriguez LU2DFX brought his own transceiver. Ronaldo Silva LU3EDZ checked and prepared the generators.

LU7XP, LU8DQ, and LU1DZ were to be the team, but almost-last-moment reasons stopped LU7XP and LU8DQ in Argentina. Ronaldo Silva LU3EDZ became the last-minute solution, and it now became a two-man team.

On board the ship, the *Bahia Paraiso*, Alberto and Ronaldo left Buenos Aires January 5, 1983, reaching Potter Cove on 25th of May Island eight days later, after a perfectly normal trip except for a storm in Drake's Passage which kept some in bed for 24 hours, seasick! From January 13 to 16, helicopters and boats landed all equipment to go to the scientific station, Teniente Jubany.

Ronaldo LU3EDZ, mechanics king, assembled generators, tower, and all during five long days of steady rain and snow and 40- to 60-kph winds with gusts to 90. A one-hour period was all the time Ronaldo could stand before getting shelter for rest again.

And then, at 1315Z January 16, CW on 20m, came the first contact, with W5RK, followed by CP7GM, LU9AX, and LU7XP. The first SSB QSO was with LU4US/mobile on January 28th, and then came LU2CM/mobile, LU1DBQ, LU4QD, and others.

During the seventh day of operation, after a 17-hour pileup, excessive earphone use caused Alberto LU1DZ trouble and fatigue, and the Teniente Jubany station physician had to stop CW operations for a while. Alberto then had a two-day SSB operation.

During a rest period, Daniel Vergani, chief botanist of the Mammalian Study Plan, took operators on a boat trip near Mariana Cove. The boat came upon four Jubarta whales, and Pablo Ljumberg, the diver managing the boat, happily got to not more than ten or fifteen meters from the whales. A possible emergency dive for all into frigid water was rather worrying!

An FT-101E transceiver and an FL-2100Z amplifier held up perfectly for the very hard 30-day operation, along with a Bencher key and an Autek manipulator with CMOS memory. SSB operations were great fun, too; discipline and respect for rules and ethics were perfectly obvious.

Lower bands, surprisingly, were very hard to operate, with QRN level close to S5, and S7 on 20 meters. This was true for weeks, which will give you an idea!

Openings to 3.5 and 7 MHz coincided with the best conditions on 14 MHz, so the question was: do a good job on the 20-meter band or try some problematic QSOs on lower bands? Conditions on 20 were good until 0430Z, but then trans-horizon radar came on, S9 plus 40! From daybreak to afternoon, until 2000Z, bands were closed, with few openings to 10 and 15 meters. Only 5 good openings on 28 MHz to Europe and North America, not so good to Africa and west Asia. Funny, during two nights on 15 meters and close to 0400Z, we could QSO Asia but signals didn't even move the S-meter! On 20 meters, from 0900Z to 1100Z, Asia was worked with the beam to the *west*! From 0230Z to 0500Z, the antenna beamed west of America presented strong echo troubles; the same to Oceania. A Tahiti signal came 30 dB over 9 no matter where the antenna was beamed!

The helicopter moved all equipment between beach and ship.

On 20 meters, an open road could be found by looking for band noise; between 330° and 30°, noise showed possibilities; due south was absolute silence.

For Alberto, a 160-meter lover, the happiest moments were when the 57 stations in South America, Central America, North America, and Europe all QSO'd 160 meters!

During rest periods, an automatic beacon operated CW at 28277, 30 Watts, dipole antenna, for ionospheric observations. It was exciting to hear the LU1UG 5-Watt beacon, vertical antenna, 28255 kHz, back in General Pico City, province of La Pampa, 124 meters above sea level (a 12BY7 and EL86).

Exciting, too, was the visit of the *Williwaw*, Willy de Rose's (VK9XR/MM) 9-meter little yacht, a traveller of all seas. He lunched with Alberto but had to leave quickly—a storm coming.

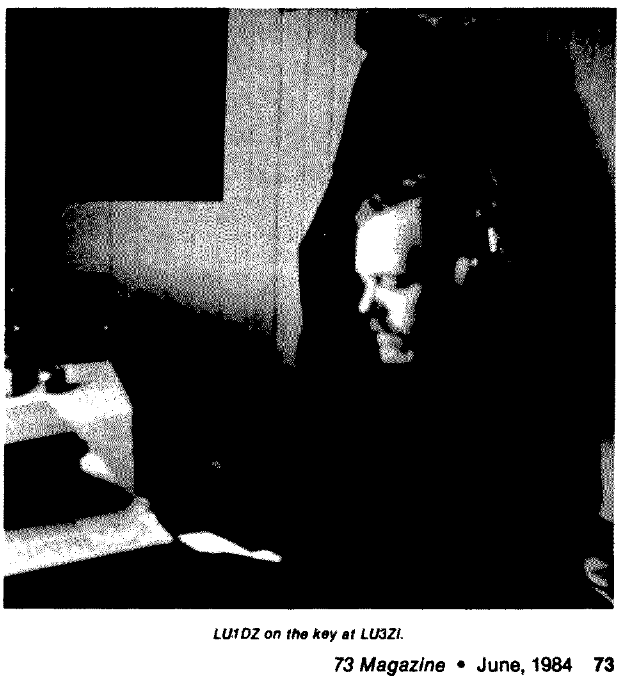
During the 28-day operation, 20,125 QSOs were made, 17,654 in CW and 2,471 SSB. Totals by bands: 160m—57, 80m—204, 40m—1,105, 20m—8,916, 15m—6,414, and 10m—3,429. Six continents and 123 countries were worked. *THE QSO* was on 160m with K7PQS/MM sailing the North Pacific off the Alaska coast! A 599 RST and even a short chat was possible!

A Palombo tribander was used for high bands; on 40m, 80m, and 160m an inverted V did well, 80m with the V at 15 meters high, and the others with the V 13 meters high.

The Teniente Jubany generator powered the station most of the time; our own generators were used only when power stopped from the base, from 0200Z to 0900Z.

During pileups, as many as 186 QSOs were realized in one hour, but after we got to 12,000 QSOs, pileups decreased and the rate came down to 120 QSOs per hour, tops.

Ending time came, and in a hurry all was disassembled because the ship was near the beach and all equipment had to be packed and taken aboard, in spite of strong winds and night coming. But anxiety to go home brought new strength to Alberto and Ronaldo, and in about ten



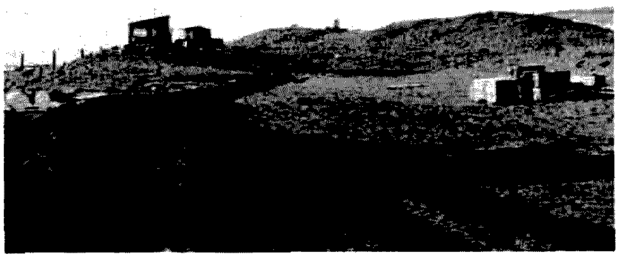
LU1DZ on the key at LU3ZI.

hours they were aboard, going back home after their 53-day adventure, a marvelous experience, and once again an expedition proved GACW's capabilities in such cases with first-class results.

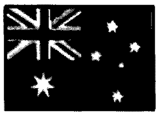
Our special gratitude to Lieutenant Colonel Luis Fontana of the DNA, to all institutions who helped us, to friends and members of the GACW, and to all operators who helped us with their patience, understanding, and support, thus making the LU3ZI South Shetland Islands DXpedition a success to be remembered.

QSLs were to be delivered to GACW, Carlos Dihel 2025, 1854 Longchamps, Buenos Aires, Argentina—an address well known to DXers.

Landing beach, 600 meters from the QTH.



QTH site at the Teniente Jubany station.



AUSTRALIA

J. E. Joyce VK3YJ
44 Wren Street
Altona 3018
Victoria
Australia

There are many contests on the amateur-radio bands throughout the year and Australia has its fair share, with most of us entering these contests, either seriously or in a lighthearted manner.

However, there is one contest in Australia that is never entered into with a flippant or lighthearted manner because of what it represents.

I am speaking, of course, of our Remembrance Day Contest, held on the closest weekend to August 15 each year to honor the Australian amateurs who lost their lives in WWII. This date, August 15, has special significance for us as it was on that day, in 1945, that all WWII hostilities ceased in the Pacific area.

The trophy itself is of typical amateur-radio-oriented design, featuring a yagi antenna mounted on a tower. This trophy is perpetual, being awarded each year to the winning division of the WIA (Wireless Institute of Australia).

As this is a local competition, with points being scored only for contacts between Australian call areas plus New Zealand (e.g., VK1 to VKØ and ZL) on all amateur bands, it does create a lot of friendly rivalry between each state's amateurs, with the winning state or division having the honor of keeping the trophy at their headquarters until they hand it over to the next winning division—but keeping it, of course, if they win it again. Their term as trophy holder is not forgotten as each winner has its name engraved on a metal shield attached to the base of the trophy.

The reigning champions of the RD Contest are the South Australians (VK5), with their latest win in 1963 making it ten wins out of the last twelve years. A remarkable achievement considering that they are competing against a much larger amateur population in the eastern states, e.g., VK2 or VK3.

We have, over recent years, had New Zealanders also entering into this competition with a lot of interest but, as yet, no luck in winning this trophy. Also in this category are the P29 (ex-VK9 Papua New Guinea) stations.

Certificates are also awarded to the top-scoring stations in each division, with the winning division being decided by the formula: Total points times weighting factor, divided by total divisional licenses.

Each division is divided as follows:

- VK1—Australian Capital Territories
- VK2—New South Wales (plus Norfolk Island, Lord Howe Island)
- VK3—Victoria (and remainder of Australian Antarctica)
- VK4—Queensland (and offshore islands—Willis and Thursday)
- VK5—South Australia (and Northern Territory—VK8)
- VK6—West Australia (and offshore islands including Cocos, Keeling, Christmas, Heard, and part of Australian Antarctica)
- VK7—Tasmania (and Macquarie Island)

The VKØ is by far the most sought after, as a contact with them gives you the greatest single number of points.

In recent years it has been the policy of the WIA to have some notable person open this contest. So far, we have had three of our Prime Ministers honoring us with their presence, the latest one being the Rt. Hon. Malcolm Fraser, in 1976. We also have had two Ministers of Communication and several State Governors, with Mr. Richard E. Butler, Dy. Sec. Gen., ITU, doing honors for the occasion in 1979, showing that members of our government and other notable dignitaries hold this contest, and what it stands for, in the highest esteem.

Listening for this contest, you won't find the usual QRM all over the bands that we hear with some of the larger contests, for we have only approximately 14,000 licensed amateurs in Australia, with a percentage of these restricted to VHF and above. Also, not all of the remaining amateurs are interested in contests, so it makes it a real relaxed style of operating, with time to have a quick chat with old friends or overseas stations looking for a short QSO or new country—particularly in our early hours of the morning when any contact to keep you awake is very welcome.

K CALLS

The K call is a special license introduced in 1980 to cater to those amateurs who hold two licenses, namely the Novice and the Limited. There has been an abnormality with this class of license which our DOC (Department of Communications) has rectified this year.

Previously, the problem had been that as a Limited license-holder able to operate on all bands above 50 MHz, you did not have to pass any CW test, giving you a very technically-minded person who has passed the equivalent of our full-call license in the theory aspect but has failed, or has not tried, the test on CW at 10 wpm, send and receive.

The Novice license gives you access to the HF bands of 80, 15, and 10 meters, but to pass this test, you need CW at 5 wpm, send and receive, so it is possible for an amateur here to hold two licenses, one for his Novice call starting with, e.g., VK3 -N, -V, or -P, and his Limited starting with VK3 -X, -Y, or -Z. The result was much confusion on the bands.

This caused our DOC to create the K call, giving the holder of both licenses the option of using (but not requiring) one callsign only, starting with a K, e.g., VK3K- -.

The problem was that as a Novice he could operate on CW, but as a Limited he could not operate CW on the higher frequencies. The DOC has now granted the holders of this special call the privilege of CW operations above 50 MHz.

So, if you hear a VK3K operating on the higher frequencies using CW, please slow down, as his CW speed may be only 5 wpm. Some, with their keyboards, will be able to operate at higher speeds, but as our exam test is with a hand key, their expertise on the keyboard is to no avail until they pass the hand-sent test to gain their full-call license.

NEW PREFIXES IN BRAZIL

Since June, 1975, Brazilian states have had a special prefix so that an immediate identification was possible for radio amateurs in Brazil as soon as the call was given. Brazil has nine regions and 26 states and territories. The PY prefix was changed to PP, PT, PR, PS, PW, PV, or PU in certain regions, according to the number of states in each.

To identify Class C radio amateurs (allowed only phone mode on 80, 160, VHF and UHF, and CW mode on all bands except 20 meters), three-letter suffixes starting with W, X, and Y were in all prefixes now in use.

Also with the PYØ prefix for Brazilian ocean islands and DXCC "countries" (Fernando de Noronha, Trindade, and S. Peter/S. Paul), this sure was a hit with prefix-hunters all over the world, delighted with new possibilities.

But what couldn't be imagined by Brazilian authorities was the tremendous run to Class C, since VHF facilities and conveniences and a "no-code" license were a very strong appeal to former CBers and others.

VHF being their only goal, almost no one cared for HF restrictions, and so VHF operators came by the thousands, thus "blowing up" the system by using up all "three-letter" combinations started by W, X, and Y! So a new law has been published in Brazil, modifying Class C prefixes and creating a new curiosity for prefix-hunters.

From February 13, 1984, Class A and B radio amateurs (except for Amapa Territory—PU8...) will continue with their actual call letters, prefixes, regions, and suffixes as before; Class A and B radio amateurs in Amapa territory will be PY8, like in Para State.

Important modifications come to Class C operators now all under PU prefixes from 1 to 9, according to the region they belong to. No more PP, PT, or PY, but only as follows:

- 1 Region—PU1—Rio de Janeiro and Espirito Santo States
- 2 Region—PU2—Sao Paulo, Goias, and Federal District
- 3 Region—PU3—Rio Grande do Sul State
- 4 Region—PU4—Minas Gerais State
- 5 Region—PU5—Parana and Santa Catarina States
- 6 Region—PU6—Bahia and Sergipe States
- 7 Region—PU7—Pernambuco, Ala-

goas, Paraiba, Rio Grande do Norte, and Ceara States

- 8 Region—PU5—Para, Amazonas, Maranhao, Piaui, Acre, Rondonia, and Amapa States, and Roraima Territory
- 9 Region—PU9—Mato Grosso and Mato Grosao do Sul States; PU0—Ocean Islands Fernando de Noronha, Trindade, S. Peter/S. Paul Islands

So what's going to happen from now on? Well, NEW Class C radio amateurs will have their calls according to PU prefix determinations; already prefixed radio amateurs a few at a time will be called to DENTEL (the Brazilian Telecommunications National Department) and will have their prefixes changed according to the new law. This will take some time, for Class C operations in Brazil are a great majority spread all over our big country; this will mean trouble for our authorities.

Due to this new law, the PU8BI operation from Macapa, in Amapa, took place under a ZY8BI call (QSL information to PY8BI as announced), a last-minute change although the *DX News* sheet and others had spread the word.

CW operators will have a better chance to QSO the new PU Class C since regulations allow them almost all CW bands except 20 meters!

de PY1CC

AMATEURS VISIT PRESIDENT FIGUEIREDO

Directors of the Brazilian Amateur Radio League (LABRE) were kindly received in the Palace by the President of Brazil, General Joao Baptista Figueiredo. Taking the opportunity, they invited him to head the first meeting of the 4th Brazilian Convention held in the city of Brasilia to celebrate the 50th anniversary of the League. The audience lasted about thirty-five minutes, and the President asked questions about amateur-radio activities in Brazil. Finishing the audience, the President surprised everybody when he said that he also expects to be an operator after his time as President. In fifty years of the League, it was the first time that a group of operators was received by a Brazilian President.

THE DEATH OF W4KCF

With deep regret, the *Bulletin* edited by the Brazilian League recorded the passing of Victor C. Clark W4KFC, President of the American Radio Relay League. The death of Vic brought a painful sense of loss to all amateurs in the world.

MEDITATION

Inge Tobias de Aguiar PY2JY is well known as the controller of the Brazilian Young Ladies Net, meeting every Wednesday on 14.248 MHz from 1900 to 2100 UTC. One night, about two years ago, while in a hospital after a surgical operation, the consequences of which were not then known, she wrote on a piece of paper this meditation, which I will translate, trying to give the same meaning as it had in Portuguese.

My God, if I die now, I will die happy
Because I knew friendship,
Kindness, collaboration, and altruism.
Since my first day as an amateur,
Up to now, nobody disappointed me.
From South to North, from West to East,
I have friends and when they hear me,
They become happy to meet me again.
A lot of them, I will never know personally.
Only through their QSLs or letters.
Hearing their voices
I'm happy when I can recognize
A few of them whom I had known personally
In someplace in the world.
They received me like a sister,
And we enjoyed ourselves with happiness,
Like very old good friends.
When I participated in any emergency operation,
I never stayed alone.
Always I had friends who helped me.
I could understand that amateur-radio activity
Is always friends working together.
When I needed help,
I received it immediately.
Nice friends!
To be an amateur is to live with happiness.
Happiness to have so many friends
On whom you can count always.
Happiness to have the chance to help someone with difficulties.
Sadness when you need to transmit bad news.
Happiness to be acquainted to another friend.
Happiness to meet someone again.
Happiness to have the chance to help impartially.
And I am happy because I am sure I performed my duty.

THE UK SCENE

I wonder at the continuing ingenuity of equipment designers to produce more and more exciting products that do not really offer any significant improvements in performance in relation to their fundamental job (or principal function)!

The prime example of this must be in the ongoing development of radio receivers for the enthusiastic listener (rather than the hi-fi enthusiast or casual observer). There do not seem to have been any significant strides in performance recently. (Performance, that is, measured by way of sensitivity, signal-to-noise ratio, intermodulation distortion, or whatever.) And yet the new models continue to hit the streets and continue to persuade large numbers of listeners to part with large quantities of hard-earned cash. The most recent model is the Sony ICF 7600D synthesized full-coverage shortwave receiver (with Band 2 FM coverage just in case you get fed up with the QRN and QSB).

I have had a Sony ICF 2001 for about 18 months since I acquired it for a trip to Nigeria. Whilst in that country I wanted, obviously, to be able to tune in to BBC World Service (if only to remind myself that home was still there). I also needed to make some subjective assessments of shortwave propagation from up country to Lagos. The ICF 2001 was a useful piece of kit, particularly in an area with a crowded shortwave spectrum. Being able to find readily a particular transmission simply by keying its frequency was a positive bonus.

That was the good news—the bad was the size and weight of the unit (although much smaller than a "conventional" shortwave receiver) and its voracious appetite for D cells which I had to take in quantity to avoid being dead in the bush.

The new model, though, comes very close to the shirt- or vest-pocket shortwave radio (of reasonable performance, that is). Although only small enough to fit into a poacher's pocket, it will fit easily into a corner of my briefcase. This means I can carry it (and its AA-size dry cells) on my many business trips. And that was the justification for paying about $250. Now when I am away on business, I can still listen to the world.

It never ceases to amaze me just how much traffic there still is on the shortwave bands. Satellites and computers and other hi-tech gadgetry are OK in their place, but, seemingly, there is still no substitute for tried and tested methods.

A recent bringing together of computers and shortwave radio may be of interest to aeronautically-minded readers. A number of utility stations around the world transmit Volmet messages giving plain-language weather information for principal airports. The broadcasts, including information such as cloud base, visibility, current weather, etc., are intended primarily for aircrew. The Royal Air Force (RAF) is responsible for some Volmet transmissions in the UK. On 4.720 MHz they now use a computer-synthesized voice. The station seems to broadcast all day.

UK CONTESTS

The Radio Society of Great Britain (RSGB) organizes and coordinates a great many contests throughout each year. Many of these are on the VHF bands and above (70 MHz, 144 MHz, 432 MHz, 1296 MHz, and higher frequencies being represented) and of little interest, therefore, to non-European readers. There are, however, a number of HF contests with an emphasis on working UK stations. Those following the publication date of this issue of *73* include:

• 2-3 June	HF National Field Day
• 23-24 June	Summer 1.8 MHz
• 15 July	QRP Field Day
• 1-2 September	SSB Field Day
• 7 October	21-28 MHz phone
• 21 October	21 MHz CW
• 10-11 November	2nd 1.8 MHz
• 12 November, 20 November, 28 November, 6 December, and 14 December	28 MHz Cumulative

In all cases, UK stations will be looking for as many DX multipliers as they can find. DX stations will find these dates useful for increasing their log entries of all UK prefixes.

ISRAEL

Ron Gang 4Z4MK
Kibbutz Urim
Negev Mobile Post Office
85530 Israel

In the last few columns, I've dealt with specific areas of amateur radio in Israel. In the meantime, a number of news items have accumulated, so the time has come to take care of these odds and ends.

CONTESTS

The Israel Amateur Radio Club Contest Committee has announced three upcoming competitions. The first two are on a national basis—the Spring Contest on Israel Independence Day, May 7, on 160, 80, and 40 meters only, and a VHF-UHF test to be held in the summer. Of interest to readers of this column is the long-awaited Israel-International DX Contest that is planned for mid-October. When details become available, they will be rushed to the international amateur press.

THE JERUSALEM AWARD

The following are the final requirements for the coveted Jerusalem Award: Ten different Israeli stations must be worked, including no less than seven Jerusalem staions. All modes and bands are permissible, and the contacts must have been made since January 1, 1983. No QSLs are necessary—just a log of the contacts, verified by two other licensed amateurs. This is to be sent along with eight IRCs to the award manager, Dr. Milt Gordon 4X8AA, PO Box 4079, Jerusalem, Israel.

The rules for the two awards of the Israel Amateur Radio Club remain unchanged and are to be found in this column in the August, 1983, issue of *73*.

STS-9

Quite a bit of interest was created here by the flight of the STS-9 space shuttle with Dr. Owen Garriott W5LFL operating on board. A few diehards assembled the antennas specified by AMSAT and kept themselves up-to-date on orbit and frequency information. To the best of my knowledge, the only contact with the *Columbia* in our region was made by our neighbor, His Majesty King Hussein JY1. In the Royal Palace, an American televison crew recorded this historic QSO, which later was televised all around the world. At the time of this contact, amateurs in the region who were monitoring W5LFL's frequency heard nothing, pointing to the fact that this contact waa a prearranged sked.

NEW REPEATER FOR TEL AVIV

Tel Aviv has become the recipient of a brand-new, two-meter repeater to replace the old one, long suffering from problems of intermod and low sensitivity. In a ceremony in the Motorola Israel offices, Yair 4X4GH, Avner 4X4GE, and David 4X4WA, representing Motorola, presented the repeater to representatives of the IARC. Since then, Aharon 4Z4AG has been testing and adjusting the machine, and by the time this is in print, it should be on the air on R7, 145.775/.175 MHz.

Yair Yosefi 4X4GH, speaking for Motorola, said that his firm views the amateur public as a technical resource in the field of electronics, and thus Motorola continues to aid the radio amateurs of Israel in developing a national repeater network. In reply, IARC president Aharon Kirschner 4X4AT gave recognition to the fact that the entire chain of IARC repeaters has been donated by Motorola Israel. Aharon praised Mr. Yosefi, who had done everything in his ability to aid the IARC. After the speeches were over, glasses were raised to toast "the repeaters that are on the way." The meeting was concluded with a guided tour of the company's labs, conducted by 4X4GE.

MINISTRY OF COMMUNICATIONS NEWS

An ongoing dialogue, once every three months, is being held with representatives of the Ministry of Communications. The following items have been concluded up to this date.

Every planned change in amateur licensing will be made known to the IARC executive before it is made public knowledge. The chart of allotted frequencies and powers will be deliberated upon by a joint group from the Ministry and the IARC. The possibility of placing IARC re-

peaters in Ministry of Communications sites will be examined.

The process of licensing visiting amateurs from abroad is to be simplified. And the physical size of the amateur license is to be reduced from certificate to wallet size.

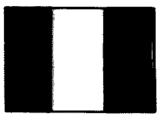
CB IN ISRAEL?

A committee from the Ministry is to be set up to examine the establishment of a code-free license according to the following guidelines: The license will be granted to those passing an exam covering conditions of the license, voice operating procedures, and safety precautions. A single crystal-controlled frequency in the 27-MHz region will be allotted, and both input and effective radiated power will be limited.

Ehud "Ed" Zager 4Z4UR has compiled a 12-page booklet dealing with lightning and communications systems. The book, distributed free of charge to IARC members, covers everything you ever wanted to know about lightning, the damages it can cause, and how to protect your station effectively from its ravages. Who knows? Maybe Ed can be convinced to put out an English edition!

Not long ago, I received an unexpected but welcome visitor, Major George Mixom N4IOM, who recently came over to these parts to serve with the Multinational Forces in the Sinai peninsula observing the Israel-Egypt peace treaty. George, a reader of this column, was on his way back to Egypt after picking up his Israeli reciprocal license in Tel Aviv and decided to drop in and say hello. There is not yet an Egyptian-American reciprocal licensing agreement, so George doesn't know if he'll be able to get permission to operate portable SU. If he does, I'm sure he'll have some big pileups to contend with.

In conclusion, I'd like to give you again the present procedure for obtaining a reciprocal license during your visit to Israel. You appear in person with your valid amateur license (not a photocopy) at the office of the Ministry of Communications, on the tenth floor of the Shalom Tower on Ahad Ha'am Street, downtown Tel Aviv's highest building. A reciprocal permit will be issued on the spot free of charge. Office hours are from 9:00 am to 1:00 pm, Sunday through Thursday, and the phone number is (03)-810278.



ITALY

Mario Ambrosi I2MQP
Via Stradella, 13
20129 Milano
Italy

The January issue of *Radio Rivista* (the Italian League magazine) dedicates one page to the awards sponsored by *73* with the reproduction of three of the awards. On the opposite page there is a photo of the Italian Islands Award. It's a very nice one and we have been writing about it to call your attention to it. (See the January column.)

In the same magazine, the cover photo and 10 pages cover usage of the personal computer in the radio shack. Particular attention is given to the Commodore 64 that is becoming very popular in Italy (we are waiting for the first copies of *RUN*) and to some locally-built interfaces.

Lots of excitement between Italian 2-meter users for the activity of W5LFL during the first days of December. Owen Garriott was heard with very strong signals on the 5th and the 7th of December and was worked by a few of the 2-meter big guns. It was not necessary, in any case, to have anything special to read him; it was enough to turn on a hand-held transceiver, but it was not easy to work him due to the huge number of people calling him.

I1NRF and I5FBP have had confirmation of contacts; more are expected.

NEW FREQUENCIES IN ITALY

The Italian Ministry of Telecommunications has given written confirmation of the new frequencies assigned to Italian operators.

- 1830-1850 kHz with a maximum output power of 100 W. For the area of Sicily, the upper limit is 1845.
- 18068-18168 kHz. For the moment, only on a secondary priority basis; awaiting the reallocation of the existing services to other frequencies to become primary.
- 24890-24990 kHz. Same situation as above.
- 1296-1298 MHz with a maximum ERP of 50 W.
- 1267-1270 MHz only for satellite service, to be assigned on a personal basis upon request.
- 10100-10150 kHz. We will be authorized to use only 10 kHz on this band. The Italian League has been requested to investigate and report what is the best part of these frequencies. The choice will be very easy as we will only have to find where the interference is lowest. In fact, Radio Moscow is received at 10115 with 9+40 signals and Arabian broadcasting uses 10120 with 9+20 reports.

MOBILE SERVICE, REPEATERS

The Ministry of Telecommunications has agreed to authorize the local operators to work mobile on 144 MHz and up with a maximum power of 10 W; no clarification is given as to whether this is input or output.

This is an important point as it recognizes the mobile service, and possibly it can be a first step to get the same kind of authorization also on HF.

The same day, the authorities recognized the existence of repeaters on the 2-meter band. Rules will be issued on this matter in a short time.

80 METERS

The 80-meter band is still a subject of dispute between the League and the Postal Administration. We can now see the possibility of finding a solution to be able to use all the band, but it will take several months to reach the final agreement.

A first step towards it is the acceptance from the Administration not to take too strong actions against hams found out of the authorized small portions of frequencies. From now on, the "bandits" will receive only a written note of the violation instead of having the license suspended for one month and a fine. All the above is a clear indication of a different attitude towards tha amateur community, and this is mainly due to the kind but firm approach taken by the Italian League. Let's hope it will continue this way.

FIRST CA RTTY

The first county RTTY award has been given to Joe I0AOF from Rome. He had to contact 12,000 US stations to be able to reach the 500 different counties. In the meantime, he has also worked 192 countries and is now trying to reach the 200 level; that is quite an achievement for a RTTYer! He is always looking for the States, so if you hear him, give a call.

* * * * *

Maybe you will be interested to know that in our country you can install a television station and broadcast porno films all through the day and you will get into no troubles.

LIBERIA

Brother Donard Steffes, C.S.C.

Brothers of the Holy Cross
St. Patrick High School
PO Box 1005
Monrovia
Republic of Liberia

Antenna parties! Amateurs here in Liberia love to go to antenna parties!

Saturday night I was talking to one of my friends on two meters. He had spent most of the day on Embassy Hill helping to put up a three-band Cushcraft. He apologized because I was not invited for the occasion. As a matter of fact, it was less than a year ago that I had helped put up the same antenna at another location. Evidently, in this instance, they had a tower on the roof of a multi-storied building and had found it necessary to build a working platform at the base of the tower. The size of the platform limited the number of "experts" that could be accommodated. I felt left out but understood that it really could not be helped. As it worked out, the antenna didn't work.

It was too late in the day to do anything more, so everyone went home and we spent the evening on two meters advising the group on what they should do the next day. I made the brilliant suggestion that they make some ohmmeter checks before they take down the whole antenna.

"There is really no reason why the thing shouldn't work."

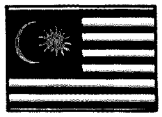
After a hard night, the group reassembled the next day, which was Sunday, and began to run tests. It turned out that the balun was shorted so they took it out and connected the coax directly to the driven element. After a few loops were put into the feedline at the upper end, the swr was almost one to one.

I mentioned above that we had put up the same antenna for another amateur less than a year previously. He was a beginner and had built his first kit, a Hot Water one zero one. That didn't work either. Just about the time we finished troubleshooting the rig and had him on the air, he was given another assignment and sent to another country. That is a chronic situation in these parts, at least so it seems.

In my experience, amateurs like to help each other, but over here in Liberia I think that this spirit is "special." The reason is, of course, that there are so few of us and the fact that parts and service are scarce. In spite of poor mail service, we manage to move radios and parts up and down the country as the necessity arises. It may take a couple of weeks or a month, but patience is something that one learns very rapidly.

We do have a good repeater and that gives us communication with amateurs who have two-meter equipment, but more importantly we have the West African Nat which meets every Sunday morning at 0800 Zulu. Most of the counties of Liberia check in on Sunday morning so we are able to pass messages. The net meets daily at 0700, but not as many of the stations are able to check in on the daily schedule.

We don't miss an antenna party if we can help it.



MALAYSIA

Sabah
East Malaysia

MOUNT KINABALU EXPEDITION

We started off from Kota Kinabalu at about 1500 local time (0700 UTC) on January 13, arriving at Kinabalu National Park at 1700. The National Park is about 48 miles (77 km) from Kota Kinabalu. There were ten of us in the group—I was the only amateur-radio operator. Eight of us managed to get beds in the hostel. (One of my friends and I had to sleep in our individual cars.) The park is 5000' (1524 meters) above sea level. The night was quite cold and it was raining.

The next day at 0700 we reported at the park headquarters located a few hundred yards from the hostel. After having coffee at the park's canteen, we started off in a hired vehicle (small truck) to the power station three miles away. From the power station, we started walking up. We had one guide and we did not hire any porter to carry our load. Every one of us carried a haversack. I had to carry a 2-meter mobile transceiver, one 12-volt, 12-Amp/hour motorcycle battery, and an antenna (Slim Jim). The antenna is a home-brew job from *Practical Wireless*, for April, 1978, F. C. Judd G2BCX.

When we started, Sylvester, one of my friends in the group, decided to help me carry the battery and the 2-meter rig. This was really appreciated because we were to climb about four miles before stopping over for the night at the Panar Laban shelter at 11,000 feet (3,000 meters). All along the way the temperature was comfortable and cool. We took some pictures; we were very tired as we got closer to Panar Laban. I felt a little short of breath and had a slight headache at the high altitude.

Some of the boys reached Panar Laban at 1230, but myself and three others arrived at 1500. It was a relief to see Panar Laban!

After getting the bed and the sleeping bag ready, I set up the equipment (FDK 800D, 2-meter FM) with the antenna between two rocks, almost on the ground. I started calling CQ at about 0500 UTC with one Watt of power, FM. Not long after the call, I heard VS5HG from Bandar Seri Begawan, Brunei; he came in 5/7. He was running 25 Watts into a groundplane. Brunei is about 320 km away. And after about 20 minutes of the QSO, during a break, I heard another station talking to VS5HG.

The other station was a bit weak with a lot of noise. Later on, I could identify that it was Gerald VS5GA. So I asked VS5HG to tell Gerald that I could hear him weakly. Later on, I understood that Gerald could hear me, so I increased power to 5 Watts. So, with me running 5 Watts and Gerald running 25 Watts, we managed a long

Try Quality Code

Using this Mod III update is much simpler than saying its title trenty times.

You TRS-80 Model III users who didn't "patch" the fine keyboard program written by Louis Graue K8TT (*73*, July, 1982) have possibly missed a nice station addition. I did not like the messy screen that the original patch-up left me, so this insert was written. Lou has graciously tested this and a previous version and reports this one runs fine on his Model I also.

The two models have partially different ROMs and the calls used to decode the miscellaneous keys read in 3840H memory location give invalid data for the Model III. This substitution instead continues the software decode.

To keep the video in sync with the sending program, unshifted arrows other than backspace are ignored. Attempts to use expanded video by loading 07H in line 3570 (right arrow) gave different, though equally fatal, problems for both models. The 10H in the listing, when shifted, will give an "extra" space bar. Sending "clear" directly to video memory bypasses a ROM routine that actually clears the screen. I retained it as is since it is not destructive.

If your editor doesn't renumber on line collision, use a smaller step for your insertion and renumber from the top when finished. The procedure—delete lines 3260 through 3550 and insert the listing shown here.

If you have included the comment lines, the renumbering will give an easy-to-read two-hundred offset to SCHR and following lines. Lou and I both experienced symbol table overflow when assembling—not enough memory. After saving the source file, eliminate as many comments or comment lines as necessary to free memory.

New Information

Lou passed along from John Meade W2XS support of BT, AA, AR, and SK. Change the data in the following lines:

Line	Character	Key
2450	BT = 0D1H	-
2580	AA = 0E5H	:
2590	AR = 0CAH	;
2610	SK = 85H	=

I key my solid-state transceiver directly with one 2N2222 driven through a 2.2k-Ohm base resistor by substituting a two (02H) for the zero in lines 220, 1290, 1590, 1770, and 1960 of the original listing. This change gives a true zero out instead of 0.4 volts.

Good luck and I hope to hear some Model III keyboards soon.■

Program listing.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½"×11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

Need schematic diagram for the Spectronics DD-1 digital frequency display which I'm using with a Yaesu FT-101E. Will make copy and return. Please send to:

Jack Duncan K0CNM
RFD 3, Crestview Drive
Denison IA 51442

Help! I now own a working NC-109 general-coverage receiver. I need information about it so that when it no longer works, I can find out why. (Also, I may want to perform modifications to it.)

Also, I have been having a terrible time tryig to connect a Western Electric #1035C3A-type touchtone™ pad to a 500-type telephone set. Any help at all will be greatly appreciated.

Newburyport MA 01950

Does anyone have a way to convert a TI 99/4a computer into a code keyboard?

B. F. Knoll KA8TIO
707 N. Wisner
Jackson MI 49202

I need an operating/service manual for a Javelin model 3100 (North American Video Corp.) closed-circuit TV camera.

Larry Steele K0UKO
5060 Chickweed Dr.
Colorado Springs CO 80917

I need any information, manuals, or schematics for the Analab Type 1100 oscilloscope with Type M 16 plug-in.

W. A. (Walt) Eddy K5QDD
111 N. Maddox
Dumas TX 79029

I am desperately looking for a few of the miniature CB walkie-talkies made by Data Magnetics Corporation called the Pocket Com. They were two channel 100-mW units, model number XB-100.

I am also interested in old CB equipment of all types and conditions. Please send info and prices.

Dennis R. Starks
Box 95
Cross Timbers MO 65634

Please, where can I find a manual for a solid-state OS-8G scope?

Russ Lawson K1MOU

I am looking for schematics and/or operator's manuals for the Regency Monitoradio 4-band receiver (model WT4) and the Johnson Viking Adventurer transmitter (no model no.). I also need crystals for the xmitter for any of the Novice bands. I will pay reasonable costs.

Carl Arndt
Box 215
Andale KS 67001

I need the schematic (only) for a Gonset model G-77 mobile transmitter. Also, I need a schematic (and possibly manual) for a Calico (California Instruments Co.) model 8000 digital voltmeter. I will pay reasonable copying costs and postage. Thank you.

W. Richmond WD4CPQ
521 Rawlings St.
Louisville KY 40217

A circuit diagram is needed for a vintage receiver (about 1940) built by the Mackay Co. for maritime communications, with regenerative control, Model 128AX. It covers .15 kHz to 640 kHz in four bands. Any help will be appreciated.

Ken Hunt WB7OVU
6519 Valhalla
Klamath Falls OR 97601

Need schematic diagram and manuals for (1) Lafayette Model HA-600A solid-state 5-band receiver, and (2) Kantronics Model 80-40B direct-conversion CW receiver. Will pay copying costs and postage.

M. K. Ellsisen W1KJF
128 Morningside Drive East
Bristol CT 06010

I need a schematic/service manual for a Kris Mach 3-B, amateur bands, 10 and 6 meter, linear amp, serial #112608. I will gladly pay for information!

William G. Sallenger
Rt. 2, Box 524
Windsor NC 27983

I'd like to hear from anyone who has successfully interfaced a Model 33 Teletype machine to a Vic-20. I want to use the Model 33 as a printer for a Vic/AIR-1 system.

Bob Howle WA4ZID
Rt. 1, Box 516
Union MS 39365

I will be on a student bicycle tour in the Cape Cod, Massachusetts, area in the month of August. I plan to operate two meters FM on the trip from the following areas: Truro, Orleans, Nantucket, Martha's Vineyard, and Plymouth and would like to hear from hams in these areas to find out what the best range repeaters are. Any info will be appreciated and acknowledged.

Jeff Gornstein KD2BE
35 Green Hill Road
Springfield NJ 07081

I have been interested in hamming for some time, but until now have never taken the appropriate time to really look into what is necessary to get started. I am a missionary with the Salvation Army, serving in Buenos Aires, Argentina. I have spoken with my father in St. Louis a number of times with the aid of a licensed operator here.

I would like to know how to get started and what equipment is necessary. I will not be able to use a rig here in Argentina, as I only have 1½ years yet here, then will be coming back to the States. And here, to be able to use a ham outfit, you have to have a complete, thorough police clearance (because of the trouble in the past with undercover groups using the radio against the government). But perhaps I can study and get in contact with a licensed operator here who is from the States.

Can you put me in touch with someone who can help me? Any help that you can give or suggest will be greatly appreciated.

Thank you again for your help.

Capitan Richard B. Forney
Ejercito de Salvacion
Sucursal 3, Casilla 194

Need the schematic and crystal multiplication factor for the KAAR FM TR500 transceiver (450 MHz).

Need schematic and info on adding FM capability to the R-482/URR-35 receiver (225-400 MHz).

Harold D. Donaldson WB6SKV
6650 Phoenix Avenue
Fair Oaks CA 95628

Recently I met a young lady who is traveling to Southern Yemen this summer to be a missionary for two years. I offered to try to set up a schedule with a ham operator in Yemen. Well, I'm sure you already know my problem—the most recent information I have does not list South Yemen as allowing third-party traffic or reciprocal operating licenses. Do you know if the US Embassy there operates a ham or MARS station (I'm in the military), and if so, what would be the best way to set up a schedule so that she could send traffic back home? Do you have any other ideas on how we could work around the third-party traffic regulations? She will be working at a hospital in an American compound only a few hours from the US Embassy.

You can be of tremendous help since I have never before attempted to set up a schedule with a DX station and am running into a lot of problems that I don't know how to work around.

David Patton WA4TQB/0
3410 El Morro Road
Colorado Springs CO 80910

Wanted: Atwater Kent speaker.

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 6

seem to quickly get lost when emotional factors come up. Let's take a look at what experience has taught us so we won't forget it.

1. In virtually every emergency, the first thing that goes out is the telephone. Storms, rain, fire, explosions, downed planes—either the wires go down or the switching systems bog down and radio is all that's left. This means that in emergencies radio is suddenly going to have to be able to handle an enormous amount of message traffic.

2. With few exceptions, the other radio services are inexperienced in dealing with emergencies, are unequipped to provide the equipment and technical people, can't interconnect with other services, and are unable to provide short-, medium-, and long-range communications. The only service really geared to providing serious emergency communications is amateur radio, and amateurs should plan to be able to intercommunicate with other services so as to help the police and fire departments, for instance, keep in touch.

3. In every emergency situation, the amount of message traffic is vastly beyond the capability of the few available trained operators to handle. This could be solved by developing equipment which does not require trained operators to use and by making the communications as high-speed as is practical.

4. Equipment and skills which are not in everyday use are just not dependable in time of emergency.

A nuclear attack (which is the most serious emergency now conceivable) is what is called the "worst case." Other than hoping that some ham will crawl out of his cellar with an intact HT or mobile HF rig and start from scratch, is there anything we can do? That scenario isn't likely to dissuade Russia from taking advantage of a perceived communications weakness some day.

Would that I could be as blasé about American security as most hams (in other words, just not even think about it) and get annoyed if the subject is brought up.

After working with a group of dedicated hams for several years on this matter of ham emergency communications, certain limiting factors have become evident. One is the relatively small number of active hams we have, particularly younger ones who will have the stamina it will take to survive an attack and set up communications. The other is the dependency on communications which are both inherently slow and depend heavily on difficult-to-learn operator skills.

Amateur radio is so pathetically far behind in technology that there is no real justification for the continuance of the hobby from that viewpoint. Indeed, our leaders have allowed the pressures from old-timers to so influence the hobby that there is little honest justification for the hobby on any basis. One of these days someone is going to say out loud that the emperor has no clothes and we could lose all those nice private frequencies. No more DX pileups. No more traffic nets sending useless messages just to do something. No more rag-chewing. No more repeater clunking. No more repeater wars. No more jamming of nets. No more bands jammed with contesters. No more certificate-hunting. No more ham club meetings with three-hour arguments on what color to paint the clubhouse. What would we do? What would we do?

A generation or two ago there were some strong justifications for amateur radio. Old-timers can remember when the rules and regulations were accepted as fundamental truths. There were four reasons cited in the rules for the existence of amateur radio as a service and for the setting aside of millions of dollars of spectrum space.

We were supposed to provide a supply of trained technicians and operators for our country in time of war. Indeed, without amateurs, WWII would have been much more difficult. But those were the days when amateurs did keep up with technology. Indeed, they were in the vanguard, inventing and pioneering virtually every major new communications technology.

Today, with most new hams going the Bash route, it is unusual to find anyone with even a vague technical background. In the meanwhile, the technology has rushed years ahead of the average amateur. Many of us were working years ahead of the average amateur. Many of us were working with digital communications over 30 years ago, yet these now-old commercial techniques are still not even on the horizon for amateur traffic nets—which are happily brass-pounding away some fifty years behind the times. How many years has it been since amateurs contributed something to communications technology?

Inventing and pioneering are the purview of youngsters and we hams have grown old and cranky. Few of us have been making any effort to get kids involved with hamming. A distressing number of the ham clubs I've visited in recent years seem to have made it a practice to discourage youngsters from joining.

Okay. Perhaps you can see that if there is going to be any realistic emergency communications system established, we are going to have to have a whole lot more hams than we do today—and they are going to have to be younger and livelier. I can just hear the curmudgeons on 75-meter phone huffing and puffing over that.

You know, I get on 20-meter phone as often as I can spare the time, and it is rare that I run into someone who is *not* retired.

You're still wondering how all this fits in with my FCC petition, right? Well, that has a lot to do with the enormous number of comments filed in response to the no-code proposal—mostly by ARRL-member ham clubs. The gist of these comments was quite consistent: No ham should be licensed without Morse-code skills because these are needed for emergency operating. The old theme of "when all else fails, CW will come through" was said so often that one might think there was some truth in it.

Okay. Let's say that whatever that number of hams agree on actually is the truth—by definition. So if we accept as a fact that we must know Morse code for use in emergency times, then it is inescapable that all hams should be able to demonstrate their competence with the code. The basis for not permitting the FCC to set up a no-code license test on 220 MHz was the need for CW skills for emergencies. So, if the hams who inundated the FCC with these statements were not lying, the logical next step was to see that CW skills are maintained. That's called putting up or shutting up.

My proposal cited the no-code responses. I read through the voluminous report from the Commission when the proposal was terminated. I concluded that the only logical reaction to this massive agreement by the ARRL clubs would be some measure to make sure that hams would not allow these critically-important CW skills to deteriorate and thus not be available when needed.

Further, since the dependence upon CW for emergency communications would pretty much rule out the development of high-speed automatic digital communications such as I have been trying to promote for the last thirty years (yes, I know when I'm licked, and we know that the volume of emergency traffic is incredible), amateurs would be doing their hobby and our country a serious disservice if they did not continue to develop their CW skills to some practical speed level.

During WWII, hundreds of thousands of people were taught to copy CW at 35 wpm—FOX, the Navy called it—also the speed which most of the commercial CW services used to use before they were automated about 40 years ago. Obviously, almost anyone can learn to copy at 35 per, so why not set that as a norm?

Sure, I knew that the same chaps who were so vehement about newcomers having to learn code would be the first to scream bloody murder if anyone suggested that sauce for the goose was sauce for the gander.

The cry would be "grandfather!", right?

Oh, I knew that the FCC would turn down the petition, probably with no good reason given. And I was correct. But I did want to hold the FCC's hand in the fire on this one because they got suckered by a bunch of clubs and old-timers into preventing amateur radio from being able to grow with the times.

On numerous occasions, I have written that I'm not at all sure that it isn't too late to save amateur radio now. A no-code license might have helped, as it did in Japan. But there it hit big so that they have about three times as many licensed amateurs as we have, and with only half our population. Odd, isn't it, that Japan is graduating seven times as many electronic engineers as we are? I wonder where they are coming from? Does anyone have an idea?

Are we going to be able to put together anything significant in the way of an emergency communications system which might possibly survive a nuclear attack? So far, I see not even a hint of hope for this. We need a massive influx of youngsters. We need to get cracking on developing already-known technology so we can have high-speed error-correcting communications which anyone can operate. We need a million new hams, all with the energy and enthusiasm to make all this happen.

I'm still trying to get the concept of ham clubs back into our high schools. I'm working on a high-tech college. My ideas are beginning to be accepted, so we'll see what happens.

Now, about the code. If you really, honestly believe that it is important, then you must agree with me that it is every bit as important to make sure that this key skill is not permitted to deteriorate through disuse. This means retesting.

If you don't agree about retesting, what other way is there to look at it except that code is not critical to getting a ham license? So, are you for code for others, but not you? Code for all? Or no-code for all? Your deal.

NEW PRODUCTS

COM-RAD'S NEW "UNTENNA"

Development of a new low-profile, vertically-polarized Untenna™ designed to outperform conventional whip antennas more than ten times the height has been announced by Com-Rad Industries of Buffalo NY.

Height reductions of 80% and more alleviate damage caused by garage doors, underground ramps, trees, drive-in or service-station canopies, and other clearance hazards, the company states.

According to Com-Rad, Untennas will benefit a wide range of mobile, portable, and fixed radio users including common carriers, and public-safety, wireless-security-system, government, military, forestry, marine, aircraft, and business/industry vehicles.

Com-Rad reports that, because of Untenna's rigid construction, mobile flutter or "picket fencing" is eliminated, resulting in base-station-quality transmission. Quieter reception with less adjacent-channel interference (intermod) is cited, and gained through Untenna's high Q design. Made of stainless steel, aluminum, phosphor bronze, and chrome plate, each antenna is noted to be highly resistant to corrosion. Unlike whip antennas, the Untenna may be enclosed in an optional weather resistant, high-impact plastic cover (Radome), which is useful also in disguising the antennas.

Untenna is currently available in five models to serve frequency ranges of 25–40, 45–85, 140–170, 210–240, and 430–470 MHz. Combination, single-feed-line models to serve multi-frequency requirements are also available.

Complete information is contained in a new, illustrated bulletin available from *Com-Rad Industries, 25 Imson Street, Buffalo NY 14210.* Reader Service number 480.

HAMTRONICS GAASFET RECEIVER PREAMP

Hamtronics, Inc., has just announced a new low-noise preamp, using a new dual-gate GaAsFET recently designed especially for service in the VHF/UHF bands. Up until now, to get the low-noise figure of a GaAsFET, a designer had to adapt a transistor really intended for microwave service. They work well, but they cost more and the devices tend to oscillate because they have so much gain at the lower VHF and UHF frequencies. Also, being single-gate devices, they tend to have the characteristically high feedback capacitance associated with triodes. This makes them hard to tame under a wide variation in load impedances.

The new LNG-( ) series of preamps solves these problems, providing good gain, moderately low noise figure (0.7 to 0.8 dB, depending on band), and low cost. The LNG-( ) series preamps cost much less than the earlier type of GaAsFET preamps. GaAsFETs typically give a wide dynamic range for good overload characteristics, and this unit is no exception. Additionally, the new dual-gate devices used in the LNG have built-in diode protection to reduce the chance of damage due to static and transients. Units operate on standard +12 to +14 V dc, and they are easy to tune. The case allows for easy mounting anywhere, including the tops of towers. LNG preamps are available for all ham bands, 10 meters through 450 MHz.

For more information, including a free catalog on other Hamtronics products, contact *Hamtronics, Inc., 65 Moul Road, Hilton NY 14468-9535; (716)-392-9430. (For overseas mailing, please send US$2.00 or 4 IRCs.)* Reader Service number 482.

HAMWARE PROGRAMS FOR THE VIC-20

Three new HAMWARE programs by John Vesty Company are said to extend the utility of VIC-20 computers to logging and QSO operations.

HAM LIST serves as a memory jogger during a QSO, quickly searching for a call and displaying data on file. The program provides for the convenient addition, revision, or deletion of entries, and a screen-review of the list.

QUICK LOG provides automatic logging of date and time, and search by call or QTH. The list can be printed, saved to tape, or screen-reviewed as desired. Time is displayed on the menu page.

QSO MANAGER combines a ten-minute identification timer and a 24-hour clock, with a screen-based notepad for use during a phone or CW QSO. The notepad incorporates a word-wrap routine to eliminate broken words at the end of a line. The timer can be set, reset, or cancelled at any time.

The three programs are available on tapes, and are designed for use with both unexpanded and expanded VIC-20 computers. Capacity of the logging programs ranges from 100 to 700 entries maximum, depending on the memory expansion used and the length of individual entries.

For further information, contact *John Vesty Company, 415 Elm Street, Fayetteville NY 13066.* Reader Service number 483.

LARSEN INTRODUCES CELLULAR ANTENNAS

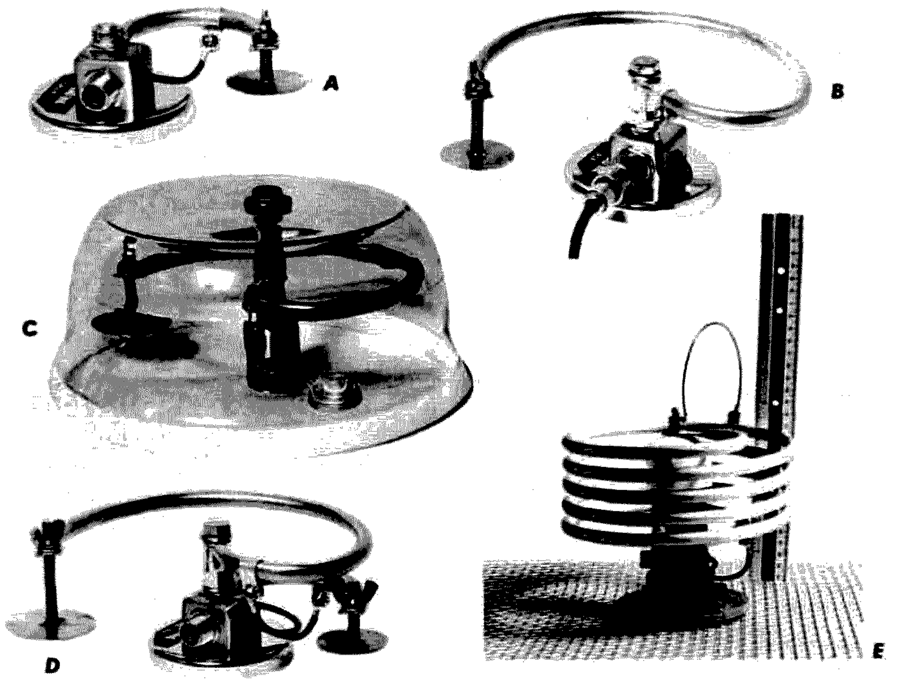
Larsen Electronics has introduced a new line of cellular antennas with a wide choice of cosmetic and mounting options. The Larsen CM series is available in gain and quarter-wave models.

The new CM-825 5/8 over 1/4 wave features an open-coil design that delivers 3-dB gain and a 90-MHz bandwidth. The base is chrome plated, while the whip has the exclusive Kulrod plating. The BCM-825 offers the same electrical configuration with a Teflon™-coated base and rod. Both are shipped with black and white plastic bases to give customers a cosmetic choice.

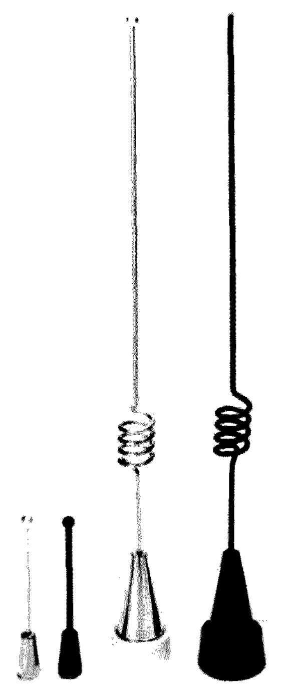
Larsen also offers CM-series quarter-wave antennas with chrome (CMQ) and black Teflon (BCMQ) finishes. The quarter-wave models provide a 90-MHz bandwidth and deliver unity gain with a compact 3" whip.

Larsen's new cellular system offers a choice of weatherproof mounting options. The CM-K/CM-B permanent mount requires a 3/4" hole or the antenna may be mounted temporarily with a mag mount or trunk-lid mount. All are available with RG-58/U or Teflon TFE low-loss coax and TMC connector. The CM permanent mount also is available with low-loss AA-3096 coax and TMC connector mount. Other connector types are available.

For more information, contact *Larsen Electronics, PO Box 1799, Vancouver WA 98668; (206)-573-2722.* Reader Service number 485.



Com-Rad Industries' Untennas. A. Model CR4A, 450–460 MHz; B. Model CR2A, 140–170 MHz; C. Optional Radome Model CR2RD (fits Untenna Models CR2A, CR3A, CR2/4A); D. Model CR2/4A dual-function, multi-frequency Untenna, 140–170 MHz, plus 440–460 MHz; E Model CR109A helical, 29–35 MHz.



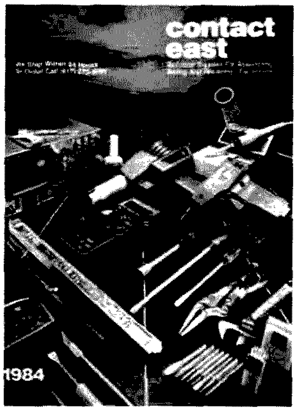
Cellular antennas from Larsen Electronics.

CONTACT EAST FREE 1984 CATALOG

Contact East is offering a free 1984 Electronic Tool and Test Instrument Catalog featuring over 5,000 quality technical products for assembling, testing, and repairing electronic equipment. This is an excellent buying guide for engineers, technicians, and researchers.

Products include precision hand tools, test instruments, tool kits, and soldering supplies, plus a new, full selection of static-control products. All products are fully illustrated with photographs, detailed descriptions, and pricing to allow for easy ordering by phone or mail. Most orders are shipped within 24 hours and carry a 100% satisfaction guarantee.

The Contact East 1984 Catalog is available from *Contact East, 7 Cypress Drive, PO Box 160, Burlington MA 01803; (617)-272-5051.* Reader Service number 478.



Free Contact East catalog.

S. E. CORPORATION'S PROTOTYPING BOARD

The "eZ Board" is a solderless experimenter system which provides a time-saving and convenient method for building experimental add-ons to interface with personal computers.

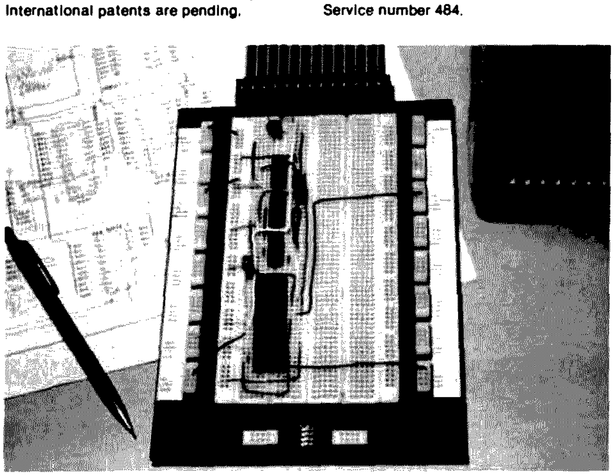
Features include a high-quality glass epoxy printed circuit board mounted with a set of solderless breadboarding units for building circuits. Four separate distribution buses with 50 tie points each can be used for power, ground, clock lines, reset commands, and more. A four-position DIP switch is mounted on the board. Each switch position connects to a set of tie-point-block sockets on either side, to aid in the development and analysis of experimental circuits. A flat ribbon cable connects the board to the computer's bus-expansion slot.

The breadboarding area consists of 1460 tie points with a capacity of sixteen 14-pin DIPs. Components with lead diameters of up to .032 simply plug in and are connected with ordinary solid hookup wire.

The board will be very useful in R & D for engineers, hobbyists, and students who wish to build their own interfaces to computers. It aids in understanding the operation of a computer's bus system and provides the function of each output terminal of the bus for use in developing add-on circuits for interfacing to a computer.

Models IPC, APC, and CPC are available for IBM-PC, Apple, and Commodore and all other hardware-compatible computers of the same type. Models for other computers will be introduced during 1984. International patents are pending.

For further information, contact *Mr. Rahim Sabadia at S. E. Corporation, PO Box 1132, Yorba Linda CA 92686; (714)-630-9335.* Reader Service number 476.



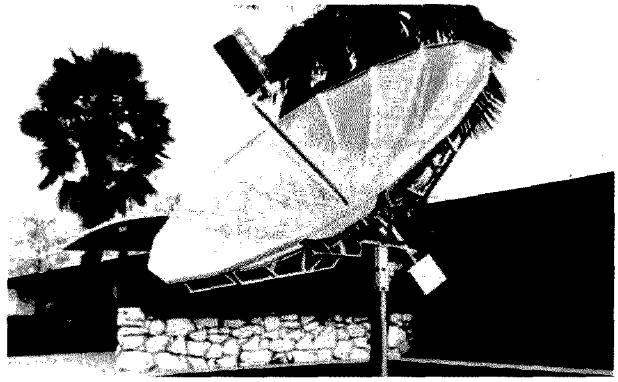
The eZ prototyping board.

AMATEUR RADIO GETS ITS VERY OWN GAME!

The Dayton Hamvention 1984 saw release of Amateur Radio's first official game product, called Hamfest!® 1984. It is produced and distributed by QCD Marketing Services, a division of QCD Publications, Inc., which publishes the ATV journal, *A5 ATV Magazine.*

Hamfest! has its own game, colorful game board, dice, money, and drawing cards. Players move around the game board buying as much ham-radio-type equipment as they can afford while trying to advance themselves from Novice- to Extra-class FCC license. Along the way, there are helping QSL cards and penalty QRM cards. Two squares are designated FCC test areas from which each player draws special FCC cards to determine whether or not he studied hard enough to pass to the next grade license. An additional two squares designate Hamfest locations from which all players begin a trade/buy/sell limited time period. There is a bank and retail store with the first player reaching the Extra-class status declared Super Ham and the winner!

Hamfest! is available at most ham-radio retail dealers or is available direct from *QCD Marketing Services, PO Box H, Lowden IA 52255; (319)-944-5421.* Reader Service number 484.



The KLM Electronics, Inc., satellite Mini-X dish.

KLM'S SATELLITE MINI-X DISH

KLM Electronics, Inc., has announced the introduction of its new Mini-X satellite TV antenna, a parabolic dish with an 8-foot diameter to meet the needs of home or commercial users with limited space.

The Mini-X is the third entry in KLM's line of modular, radar-mesh, parabolic dishes. Its modular design permits fast shipment and easy assembly even by amateurs using simple tools. The smaller, lighter, Mini-X can be assembled by two people in 1½ hours or less or by 1 person in about 2 hours.

The Mini-X employs the same basic modular design as KLM's X-11 and X-16 antennas, with the same survival capabilities against the elements, including the ability to withstand 100-mph winds. It has 16 ribs compared to 24 for the 11-foot X-11.

The Mini-X operates at 55% efficiency, like the X-11. Its f/d ratio is .34 compared with .47 for its larger cousin. It is available with a low-cost, manual-type mount or with a KLM polar mount and tangential drive compatible with KLM motor drives. The Mini-X can be ordered in dark green, black, or brown.

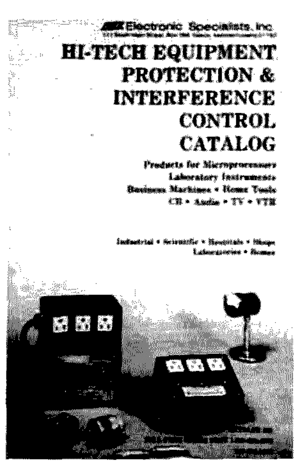
For further information, contact *KLM Electronics, Inc., 16890 Church Street, Morgan Hill CA 95037; (212)-986-6668.* Reader Service number 479.

ELECTRONIC SPECIALISTS' HAM GEAR PROTECTION

Protection and interference control products are presented in a new 40-page catalog from Electronic Specialists. Costly damage from lightning or power-line spikes can be prevented, and disruptions or interference from power-line-carried EMI and RFI can be controlled. Protective devices for ham gear include ac line-voltage regulators and conditioners, modem and phone-line surge suppressors as well as equipment isolators and filter/suppressors.

Typical protection and interference problems are described, together with suggested solutions for various ham and communication installations. Catalog 341 also describes numerous applications for hi-tech equipment protection and interference control.

For further information or to obtain, write *Electronic Specialists, Inc., 171 South Main St., PO Box 389, Natick MA 01760; (800)-225-4876.* Reader Service number 481.



Electronic Specialists' catalog of ham gear protective devices.

THE MCM ELECTRONICS DMM/DCM METER

MCM Electronics, a parts and accessories distributor to the electronic service industry, has introduced the Tenma combination DMM/DCM meter with hFe transistor-gain tester. Users can easily read voltage, current, resistance, capacitance, and hFe on the clear ½-inch, 3½-digit LCD display. It saves time and money by eliminating the use of both a conventional capacitance and a multimeter.

Lightweight and compact for use in the

The MCM Electronics DMM/DCM meter.

field or on the bench, the meter's in-line push-buttons allow for easy one-hand operation.

The capacitance-measuring socket gives direct measurements of capacitors, along with a transistor hFe. The color-coded panel allows users easy identification of function and range settings.

Safety features include input overload protection, single fusing (with spare fuse inside), and stress relief test leads. The Tenma combination DMM/DCM meter comes in a convenient carrying case, with alligator-clip hFe leads, and has a one-year warranty. Battery-operated, the LCD display indicates low battery condition. To get further information or to order, with 24-hour delivery, call toll-free *(800)-543-4330 (in Ohio, (800)-762-4313).* Reader Service number 477.

REVIEW

TRIO-KENWOOD TW-4000A

Trio-Kenwood unveiled the TW-4000A at the 1983 Dayton Hamvention, and that is where I got my first look at one. The model on display had the optional VS-1 voice synthesizer installed, and after a few minutes playing time, I decided that I had to have one. In fact, I didn't get around to purchasing one until that fall. The local ham-radio store, R & L Electronics, let me play with a powered-up unit and demonstrated features and the various options that they stocked. I'm sorry, but you just can't get that kind of service through an 800-number purchase. I ended up going home with the TW-4000A, the VS-1, and the MA-4000 dual-band mobile antenna.

The "FM Dual-bander," as Kenwood likes to call it, is just that. Capable of transceiving on either 2 meters or 440 MHz, it outputs a respectable 25 Watts on both bands. It is one of the very few rigs on the market capable of more than 10 Watts output on 440. My own unit actually measured about 30 Watts on both bands with a Bird® wattmeter.

A long list of other main features includes: a large, easy-to-read liquid-crystal display, an included MC-48 touchtone™ microphone, battery backup (nice when you take that rig into the house at night), priority watch which switches the receiver back to channel one for one second out of ten to watch for calls, and dual vfo's.

The TW-4000A has three main options available. These include the VS-1 voice synthesizer, the TU-4C Continuous-Tone Coded Squelch System (CTCSS) tone encoder, and the MA-4000 dual-band mobile antenna. The VS-1 voice-synthesizer board came in a painfully small box but included a complete set of instructions for installation and use (in two languages). English and Japanese, as if you hadn't guessed. Installation went smoothly, as per instructions, and left me with an excess board containing the previous beeper circuitry. I kept mine... I don't know why. The VS-1 speaks in two languages (go ahead, try to guess) at three speeds. The English voice has an accent of distinctly Japanese female extraction, but it is easily understood. The flip of a switch gives you the same vocabulary in Japanese, to the great delight of guests and children. Watch out for those kids, though; it takes them only a short while to pick it up and they'll be driving you nuts in Japanese. A switch is located on the bottom of the rig that allows you to turn off the voice synthesizer when desired. This is an important feature when on long trips and the XYL is trying to sleep or when she's driving and you want to wander the band without distracting her.

The MA-4000 dual-band antenna is an interesting affair. On 2 meters it is a center-trapped 5/8 wave. On 440 MHz, however, the trap phases two ½ waves in collinear form. Yeah, I know. You've gotta see it. The base of the antenna contains the equivalent of a PL-259. This unique feature raises all kinds of interesting mounting possibilities... and problems. A magnetic mount is available and it is quite strong. Personally, I am a fervent believer in permanent-mount antennas but could find no mount of that configuration. So, I improvised. Those who cringe at the thought of drilling holes in an automobile body should shield their eyes. I found a slightly-longer-than-usual SO-239 socket, drilled a hole in the center of the roof to fit, and tightened a nut down on an "O" ring purchased from a local hardware store. This arrangement has served me faithfully with no leaks for six months. The TU-4C programmable tone encoder is also accessible from the bottom of the radio and allows the setting of one tone each for both VHF and UFH. The TU-4C will generate any of the 37 standard subaudible tones by setting a DIP switch according to the chart included in the owner's manual.

Now a word about whistles and bells. You know, those little features that make or break the long-term ownership of the rig. The dimmer switch dims the display for night driving (you'd be amazed at how bright it is otherwise!). The "scan" feature is always nice when you're bored or on the open road. "Skip" allows the memory scan to bypass unwanted channels. "Reverse" lets one check the input of a repeater to assess simplex possibilities. The microphone-monitoring feature provides a visual indication on the liquid-crystal display as to whether or not your mike or touchtones are working. The owner's manual is extensive and quite complete.

Then comes my pet peeve with many rigs—the included schematic. The schematic diagram that comes with some rigs is either so small that you need a photo enlarger to read it or is spread among several pages of a booklet, preventing easy interpretation. The person that drew the schematic for the TW-4000A should get a pat on the back and a raise. Drawn on both sides of a nice big 16" × 23" sheet of paper, it is well marked and easy to read. The interconnect lines are spaced 60 thousandths of an inch. This is a considerable improvement over the more common 20-thousandths spacing, especially when ten or so of these lines run parallel for any distance. The PLL unit and MC-48 microphone are drawn on the back in nice open lines. Regrettably, as with many other Kenwood radios, no schematic diagram of the microprocessor unit is provided. For those that never work on their own radios, this is of little consequence. Each of these features by itself is not enough to recommend a radio, but altogether they are a formidable package.

The Kenwood TW-4000A is far and away the best mobile rig I've ever owned and, for the person interested in FM only, it makes a very respectable home station as well.

For more information, contact *Trio-Kenwood Communications, 1111 W. Walnut, Compton CA 90220.*

THOMPSON SOFTWARE MORSE-CODE TRANSLATOR

Outstanding. That is my overall assessment of the new program offered by Thompson Software. The Morse-Code Translator decodes CW and scrolls the output from right to left on a single line across the monitor screen. Input is direct from the receiver headphone jack to the Timex 1000 computer earphone connector. No terminal unit, hardware modifications, or special attachments are needed. What's more, the program also generates CW and sends it via the microphone connector. The best part (aside from the price) is that the program fits into the 2K memory of the unexpanded Timex 1000. I have not tried the program in the Sinclair ZX-81 or the Timex 1500; however, due to their similarity to the model 1000, I suspect that there would be no compatibility problems.

The translator decodes letters, numbers, and 18 other characters (such as $\overline{AR}$, comma, period, etc.). To use the program, load the cassette in the normal fashion; the program is self starting. A brief copyright notice appears on the screen and then the receive mode, shown in Fig. 1, appears. By entering a period, the screen switches to the format in Fig. 2, the code-speed input. Once selected (the range is 9 to 100 wpm), the screen switches to Fig. 3, which gives the option of sending or receiving.

I have confined myself to CW reception; sending requires an audio amplifier connected to the computer microphone port. Reception has been a very pleasant surprise. The computer does an excellent job of scrolling the translated CW on a single line, a total of 32 characters wide.

I listened on 15, 20, 40, and 80 meters and found the reception very good even in noisy situations. My receiver was a Ten-Tec Argonaut with a Murch dipole. I then switched to my Sony ICF 2001 to poke around the SW bands, looking for commercial and government CW stations. I found several and had no trouble with the translating. Computer-generated noise was barely noticeable on the Ten-Tec but was somewhat obtrusive on the Sony. Reception was always very good when proper CW spacing was found. Sloppy fists resulted in the scrolling of various "E" and "T" characters. The old adage, "garbage-in, garbage-out," is very clearly demonstrated in the Thompson Translator. See Fig. 4 for a sample of the output when in the receive mode.

The program has been copyrighted and cannot be discussed in any detail. However, it is similar to many other Timex 1000 CW programs previously published in both *QZX* and *QEX* newsletters. The first line is a REM statement that contains the machine language. Typically, ML is loaded by means of a short routine that is subsequently deleted before using the program:

```
FOR I = 16000 TO 17000
INPUT N
POKE I,N
NEXT I
```

The balance of the program is devoted to the formatting of the screen, selecting the CW speed variable, and various timing and USR commands. This is an elegant little program that does a great job with little memory.

Why use the Timex 1000 computer for CW reception when there are so many alternatives? My reason is the low cost of the unit. Available options include a dedicated microprocessor like the HAL RTTY unit or a code reader like the Microcraft CODE*STAR or an MFJ terminal unit for a home computer. All of these cost far more than my calculator-sized Timex. Originally priced at $150, this computer can now be purchased for as little as $9.95 on special sales. With something like 750,000 units in circulation, it should be no problem to acquire one secondhand. I bought mine for $15.00 at a flea market.

There are several options for CW reception with the Timex 1000. The cream of the crop is the "CWSS" split-screen CW transceiver package that includes a program and hardware from NU4V. Priced at $90, this unit is reported to be an excellent performer. It comes in a kit that must be assembled and plugged into the rear of

Fig. 1.

Fig. 2.

Fig. 3.

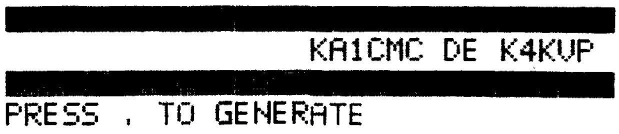

Fig. 4.

the computer. A simpler method requires a knowledge of transistor-to-transistor logic and the assembly of a terminal unit. This can be connected to pin 20 of IC1 of the Timex computer, and with the right software, it will do a good job of receiving CW. I zapped an IC with some ill-advised modifications of this sort. Static electricity does not mix with ICs very well. The Thompson Translator ($9.95) is the cheapest solution that I have encountered. Input via the microphone port is directed to pin 20 of IC1 without requirement of major surgery on the computer.

All in all, I give very high marks to the Thompson Software CW Translator and recommend it without reservation. I hope that the Thompson staff is hard at work on a RTTY program. Both programs would be welcome additions to Timex software libraries. For further information, contact *Thompson Software, PO Box 1266, Lombard IL 60148.* Reader Service number 486.

REGENCY Z30 SCANNER

The Regency Model Z30 is a full-feature scanner that should appeal to those requiring maximum operator flexibility. Covering the three FM bands, the Z30 features 30 programmable channels and a host of features provided by microprocessor control. A clock and alarm clock are included. Although designed for home use, the monitor can operate in a mobile environment using a provided 12-V power connector. A telescoping antenna is included with the unit, and although fine for normal use, a connector is provided for an external antenna.

As soon as I unpacked the Z30, I was impressed by the layout of the controls. Unlike some devices with keys so small a pencil tip is required equipment, the Regency features a full-size, 24-key touchpad and power, volume, and squelch controls. Setting frequencies is a snap. Programming the frequency of a local repeater was accomplished by first depressing the MANUAL button. A loud "beep" announces contact closure in no uncertain terms. The display (of the bright-green vacuum-fluorescent type) indicates the channel number being programmed—in my case "CH 01". The desired frequency is then entered digit by digit on the keypad. Any programming mistake is easily fixed by using the CLEAR button and reentering the numbers. I managed to correctly enter 147.375. Depressing ENTER associates the channel and frequency. No band-switching is required, as any frequency within the three bands can be associated with any channel. All 30 channels are programmed in similar fashion. A DISPLAY button allows the user to immediately identify any of the 30 possible channel-frequency relationships. Any errors or incorrect control sequences are indicated by English-like error messages created by the microprocessor.

The Z30 supports all popular scanner functions. Hidden frequencies within a band are isolated easily using the SEARCH function. The upper- and lower-frequency ranges of the search are entered using multipurpose keys. After depressing SCAN, any reception within the bounds locks the receiver and the frequency is displayed. Two options may then be employed. If you are like me, it takes a few moments to write down a new frequency. A DELAY function causes the Z30 to hold for four seconds after carrier disappears before scanning is resumed. If you like what you hear on a new channel, depressing HOLD keeps you there. Searching is terminated at any time by using any other function key.

A favorite channel may be checked every two seconds for activity by programming it into CH 01 and activating the PRIORITY function with a single keystroke. A simple scan of preprogrammed channels is initiated by depressing SCAN. A DELAY option holds each reception for two seconds after transmission to allow responses to be heard. A single channel is continuously monitored by selecting the CH with the MANUAL button.

All in all, I found the Regency Z30 easy to set up and understand. Regency did not overlook receiver performance in this design. Some of the allband, fully-synthesized machines function well on one band and suffer on others. Since the Z30 owner's manual actually published specifications for the bands 30-50 MHz, 144-174 MHz, and 440-512 MHz, we decided to check some of them. A friend who is a repeater owner/operator provided the equipment and expertise required to run accurate tests. Receiver sensitivity (12 dB Sinad) exceeded the published figures of .35 uV at 40 MHz, .4 uV at 160 MHz, and .5 uV at 465 MHz by comfortable margins. Operating a 2-meter hand-held in the same room did not cause the entire middle band to go dead. Squelch action is crisp and the audio quality is acceptable. A list of synthesizer "birdies" is provided in the owner's manual. On my sample, some were present, but at least the owner is forewarned.

The Z30 package is rounded off with a programmable time-of-day clock and alarm clock. These clocks are programmed via the keypad. The alarm, when it sounds, is very loud, unmelodious, and guaranteed to wake up anyone. (I'll bet on that!) A DIM switch allows the normally-bright display to be dimmed or turned off altogether at night. A capacitor backup system is claimed to hold all programmed functions for a week when ac power is absent. I didn't test this function as I play with my Z30 daily, but no data was lost while transferring the unit to my car.

I have two units with the Z30. The base plate for the touchpad is a baked, metallic-brown color. The numbers and functions printed by the keys are almost unreadable under dim or indirect illumination. The "beep" tone used to verify key closures and for the alarm clock is unnaturally loud and harsh. However, the features and performance of the Z30 outweigh these minor problems. The 20-page operator's manual is complete and understandable. Full technical specifications, troubleshooting guide, and "national frequency list" are included.

For additional information, contact *Regency Electronics, Inc., 7707 Records St., Indianapolis IN 46226-9986; (317)-545-4281.* Reader Service number 467.

WHAT DO *YOU* THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Okay, so that's one! You see, as I begin the eighth year of this column, I have to admit to making a mistake. I don't make many here, but this one is a doozy. Thanks and a tip of the cap to Ed Duellman K9FWR, Duane Vincent KA7JEX, and the countless others who will no doubt write between the time I write this month's column and when it sees print.

To explain, in the April column I discussed hooking a Murray-encoded teleprinter to an ASCII port of a computer, in that case, a Texas Instruments TI-99/4A. The problem was that I was referring to a Teletype Model KSR-35 as a Murray machine. It is not. The Model 35 is a 110-baud ASCII machine. The problem arose in my scribbled note to myself, wherein I changed the "35" to a "32". The Model 32 is the Murray version of the commonly found Model 33, which is also an ASCII machine.

So, if you all will take a pencil to your April issue and change the reference to a Model 35 to a Model 32, all will come out all right. No, this was not an intentional April Fool's joke, although it seems to look like one. And, fortunately, the general ASCII-to-Murray discussion of last month remains unaffected.

As I mentioned above, this is the start of the eighth year of RTTY Loop. Because we have picked up a good number of readers in the last few years, I think it is time to review some general points that may be confusing to the newcomers.

What is RTTY? "RTTY" stands for radioteletype, a mode wherein amateur-radio communication is maintained using signals decoded to activate various kinds of teleprinters or computers.

What kind of printers or computers? Some of the pioneering work in RTTY was done with teleprinters which look like the ones you see in newsroom photos of the 1950s. Various designations are given to them, most of them relating to Teletype Corporation model numbers. After a period of slow growth, where mostly mechanical teleprinters were in use, RTTY is now going through a boom with the arrival of microcomputers. Software, that is, programs, are available for about any home computer to turn it into a RTTY terminal.

What do you talk about? Well, what do you talk about on ham radio in general? Sure, topics include the equipment you are running, the weather, and the usual run-of-the-mill stuff. But, since today's RTTYers are likely to be in the forefront of digital technology, computers and the like are also active topics. Not only that, but RTTY stations also can send long texts such as messages, programs, and the like, and, especially around holidays, some of the famous RTTY pictures.

Where can I find a RTTY station? Still popular after all these years, look for the doodle-do of RTTY signals around 3520 kHz or 14080 kHz. There are other spots, and you may even find a local two-meter repeater with a RTTY net.

How much will it cost to get on RTTY? How much does a car cost? You can probably locate an old teleprinter around for a few dollars. Simple AFSK generators and demodulators have been published here and will be published in the future as new designs appear. Or, if you have a microcomputer such as a CoCo or any of the 6502 machines, a sawbuck or two should bring you enough programming to put that machine on the air. It's clearly not out of reach for most hams.

Where can I find out more? You knew there had to be a point to all of this, right? Well, you are holding, in your hand, a potent source of RTTY information. Keep reading *73*, keep reading RTTY Loop, and you should be able to get all the information you need.

I was not kidding about the bargain machines, folks. As I write this column, I am recovering from a day at the Greater Baltimore Hamfest and Computerfest. Next month I hope to print a few photos of the sights. Deadline precludes getting the film processed this month, but let me tell you—Model 15 and Model 33 teleprinters were being sold for less than fifty dollars, some for much less! The computer displays, tables and tables of them, often showed RTTY programs available. The tide is turning, ladies and gentlemen, and RTTY is growing faster then ever!

I have a letter here from Eric W. Davenport N4DTE who is using a 6809-based microcomputer under the FLEX operating system and is looking for a RTTY program to use on that computer. Well, Eric, I have looked around and, sorry to say, can find nothing that would support the system you are using. That is not to say it does not exist, though, and if any readers are using such a system on RTTY, I would be happy to hear about it and will pass the information along to Eric. One source you might try is *'68' Micro Journal*, a monthly magazine devoted to the 68xx series of computers. They lean toward FLEX and 6809s, so it sounds like your league. You can subscribe for one year by sending $24.50 to *'68' Micro Journal*, 5900 Cassandra Smith, PO Box 849, Hixson TN 37343. Be sure to drop my name, ok?

One more ham who has found happiness with a TI-99/4A is Paul Schmidt W9HD. Paul passes along his comments, with the note that his computer is on the air with the aid of the Kantronics Hamsoft program and the AEA CP-1 "Computer Patch." He enjoys operating RTTY, but I have to pass along his last few lines. You see, Paul works as a radio operator on a supertanker, and he writes, "By the way, I'm not too enthusiastic about AMTOR. On the ocean, we have SITOR and MARISAT. On this ship, we have neither one. I send my traffic a letter at a time on CW. How about that?" Thanks, Paul, and I do appreciate the comments.

Here is another letter from a ham trying to put yet another kind of computer onto RTTY. John A. Palese, Jr. WB9JPH/5

writes several questions. The first seeks the existence of a program to place an Osborne 1 on the air on Morse, Murray, and ASCII. Well, the last one is easy, John. Any terminal program, such as the public domain MODEM7, will do fine to produce ASCII. I have not seen anything on the boards for RTTY or CW, but I'll keep my screen clean and looking.

John's next question shall be paraphrased for obvious reasons. "What do you think of the Milchig computer with a Fleischig interface for use on RTTY?" Unless I have seen the combination in question, there is no way I can answer the question! As a rule, any reputable product appears to be functional. I have received very few "lemon" reports, and those I try to pass along as best I can here in the column, usually quoting the reviewing amateur directly. I would encourage you to look around to see if you can play with someone else's system in your area before you buy. I don't know that I would base the purchase of a particular microcomputer on the desire to run RTTY, however. It is rapidly appearing that any one of the "consumer" line has supporting software.

So you see, my overall advice if you want to run a computer on RTTY is to first pick the computer. Pick it for what it can do within, and without, amateur radio. After all, a computer is too powerful a tool to limit to one use only. For that you could get a dedicated terminal. Then look for software and interfaces that appeal to you. Believe me, whatever I have seen I write about. If I have not written up a particular program or interface, it is not necessarily because it is bad; I probably have not had any hands-on exposure to it. And as stated here before, I won't write up an item based on a press release unless there are extenuating circumstances. I have done that in the past and we all got bitten—no more!

Hope that helps you out, John, and thanks for the note.

Because of the two-month delay between the time I write this column and publication, I am dragging my feet this month on the information sheet mentioned last month. I want to see what the response is and attempt to react accordingly. So I am still offering the first of several planned information sheets on RTTY. Simply send a self-addressed, stamped envelope or sufficient US funds for postage to foreign stations with $2.00 to the above address for the first sheet, an elementary introduction to RTTY. If the demand keeps up, sheets will be introduced to cover many of the elementary topics discussed in past columns.

Next month will include a look at the recent hamfest, if the pictures come out, and more of this and that. Let me hear from you, then look for your name here, in RTTY Loop.

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

BASIC COMPUTING

If you're a forward-thinking ham (as opposed to those lids who devote their lives to repeaters and rag-chew nets), you probably own a microcompter. But do you ever actually program your machine? Probably. But odds are that you get more use out of canned software than your own creations.

As my dear friend Doctor Digital always says, programming is fun. That may be true. But which language is best?

Basic is by far the most popular micro language. Basic in ROM is a standard feature on most personal computers. Still, its awkward syntax and arcane structure make it a clumsy language to use in all but the most simple (dare I say basic?) applications. Pascal is much nicer, but has been slow to catch on. Everyone likes Pascal, but few actually seem to write software with it. Assembler is better yet, but is much too complicated for newcomers to handle.

So we're stuck with Basic. All in all, it's not an impossible language to work with, given its inherent limitations. More than one Field Day logging program has been written in this language and I suppose hams will continue to use Basic for years to come.

This month, for better or worse, FUN! looks at the world of Basic. GOTO Element 1.

ELEMENT 1
MULTIPLE CHOICE

1) The original form of Basic is known as:
   1) Dartmouth Basic
   2) Princeton Basic
   3) Original Basic
   4) Basic Basic

2) Which of the following Extended Color Basic commands tells a Radio Shack TRS-80 Color Computer to send sound through a TV speaker?
   1) SOUND ON
   2) SPEAKER ON
   3) AUDIO ON
   4) TV ON

3) Who invented Basic?
   1) Stan Wright and Herb Anderson
   2) Frank Sullivan and Steven Klein
   3) Thomas McIntire and Steve Jobs
   4) John Kemeny and Thomas Kurtz

4) What function does the system command CALL – 151 serve on an Apple II?
   1) Puts the computer into the monitor mode
   2) Initializes slot 1
   3) Activates the computer's 80-column card
   4) POKES the decimal value 151 into memory location 16789

5) What function does IPL serve on Radio Shack's Model 100?
   1) Automatically executes a specified program as soon as the computer is switched on
   2) Sets the computer's real-time clock/calendar
   3) Initializes the 300 baud modem
   4) It serves no purpose

6) The Commodore 64 comes with how many bytes of random-access memory?
   1) 16K bytes
   2) 32K bytes
   3) 48K bytes
   4) 64K bytes

7) CP/M is:
   1) A language
   2) An operating system
   3) A local area network
   4) A popular word-processing program

8) PRINT USING:
   1) Is not a Basic statement
   2) Tells the computer to print strings using a non-ASCII format
   3) Prints numbers or strings in a variable format
   4) Is a standard part of Applesoft Basic

9) LLIST, in Microsoft Basic:
   1) Prints listings lengthwise
   2) Cannot be used as a program statement
   3) Sends a listing in memory to a printer
   4) Prints listings twice

10) On a TRS-80 Model III, PRINT@:
   1) Would print the character "@"
   2) Tells the computer to print a character at a specific point on the video display
   3) Is never used
   4) Tells the computer to output to a printer

ELEMENT 2
TRUE-FALSE

Separate the working from the non-functional Basic program lines.

	True	False
1) 10 ? "HELLO"	____	____
2) 10 C = A PLUS B	____	____
3) 10 LET A = B	____	____
4) 10 FOR I = 1 – 5	____	____
5) 10 A + B = C	____	____
6) 10 C = A × B	____	____
7) 10 IF B = C	____	____
8) 10 GOTO	____	____
9) 10 INPUT 10	____	____
10) 10 PEEK 16789	____	____

ELEMENT 3
SCRAMBLED WORDS

Unscramble the following Basic commands and statements:

UNR	TISL	RITPLN
PUINT	BUGOS	EWN
LAREC	HENT	POST
DNE	FENTID	MID

ELEMENT 4
FILL IN THE BLANK

1) Many Basic programs use a _____/NEXT loop.
2) Every RETURN must have a _____.
3) Programmer comments are contained in a _____ statement.
4) IF A = 20 _____ 50
5) To get a result from READ, one must supply at least one _____ statement.

THE ANSWERS

Element 1:
1—1, 2—3, 3—4, 4—1, 5—1, 6—4, 7—2, 8—3, 9—3, 10—2.

Element 2:

1—True	The question mark will work as a PRINT statement or command on most personal computers.
2—True	But never A + B = C.
3—True	LET is optional, but you can toss it in if you want to waste memory.
4—False	TO, not "–", is what works.
5—False	See question 2.
6—False	Multiply with "*" not "×."
7—False	Not a complete statement. Toss in a THEN.
8—False	No line number specified.
9—False	Needs a variable.
10—False	Memory address must be in parentheses.

Element 3:
RUN, LIST, LPRINT; INPUT, GOSUB, NEW; CLEAR, THEN, STOP; END, DEFINT, DIM.

Element 4:
1—FOR
2—GOSUB
3—REM
4—THEN
5—DATA

SCORING

Element 1:
Two and one-half points for each correct answer.
Element 2:
Two and one-half points for each correct answer.
Element 3:
Two points for each word unscrambled.
Element 4:
Five points for each word correctly filled in.

Have you conquered the basics of Basic?

1-20 points—	Think computers are just a fad
21-40 points—	Think computer prices are still too high
41-60 points—	Happy to run canned software
61-80 points—	A true-blue hacker
81-100 points—	Program in machine code for kicks

HAM HELP

I need a schematic and service manual for the Lafayette BCR-101 shortwave receiver.

Marvin Hees W2WKU
204 Queensway Road
Elma NY 14059

Wanted: Program for the Commodore VIC-20 and/or C-64 computer to allow them to be used as an electronic mailbox (RBBS or MSO) on the air on ASCII and/or Baudot; may be commercial program or home brew.

SSG. Gary E. Kohtala DA2XF
USAFS-A, Box 1418
APO NY 09458

Wanted: An instruction manual for a Leeds and Northrup galvanometer bridge, catalog #4270, serial #1041207. Will gladly pay copying and mailing costs.

Vernon Jones WB1BVH
32 Cat Mousam Road
Kennebunk ME 04043

Can you help me find a book for trouble-shooting radio problems? Especially receivers. I'd like to understand the theory and what to check for with particular symptoms.

Ray Poll
2322 Calumet
Flint MI 48503

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ARRL VHF QSO PARTY
Starts: 1800 GMT June 9
Ends: 0300 GMT June 11

Sponsored by the ARRL, the object is to work as many amateur stations in as many different ARRL sections and countries as possible using authorized amateur frequencies above 50 MHz.

Operating categories include single-operator using multi- or single band, or multi-operator. Single-operator stations must use one person for all operating and logging functions. Single-operator stations may submit single-band scores for 50, 144, 220, 432, and 1296-and-up categories. Contacts may be made on any and all bands without jeopardizing single-band entry status. Such additional contacts are encouraged and should be reported.

Multi-operator stations must locate all equipment (including antennas) within a 300-meter circle.

Stations may be worked once per band, regardless of mode. Each QSO must be acknowledged; one-way exchanges do not count. Foreign stations may work only stations in the USA, Canada, and US possessions for contest credit.

Retransmitting either or both stations or use of repeater frequencies is not permitted. Contest entrants may not transmit on repeaters or repeater frequencies on 2 meters to solicit contacts. Use of the national calling frequency (146.52) or immediate adjacent guard frequencies is also prohibited. Only recognized simplex frequencies may be used, such as 144.90 to 145.10; 146.49, .55, and .58; and 147.42, .45, .48, .51, .54, and .57 MHz on the 2-meter band. Local-option simplex channels and frequencies adjacent to the above that do not violate the intent of the contest rules or the spirit and intent of the band plans as recommended in the *ARRL Repeater Directory* may be used for contest purposes.

All operation must be fixed, portable, or mobile under one call from one ARRL section. A transmitter used to contact one or more stations cannot be used under any other call during the contest period with the exception of family stations where more than one call is assigned to one location by FCC/DOC. Also, one operator may not give out contest QSOs using more than one callsign from any one location.

Only one signal per band at any given time is permitted, regardless of mode. While no minimum distance is specified for contacts, equipment should be capable of real communications (i.e., able to communicate over at least a mile). Multi-operator stations may not include QSOs with their own operators except on frequencies higher than 2.3 GHz. Even then, a complete, different station must exist for each QSO made under these conditions.

Above 300 GHz, contacts are permitted for contest credit only between licensed amateurs of Technician class or higher using coherent radiation on transmission (e.g., laser) and employing at least one stage of electronic detection on receive.

EXCHANGE:

Name of section, VE province, or DX country. Must be acknowledged by both operators for credit by either.

SCORING:

Count one point for each complete 50- or 144-MHz QSO, 2 points for each 220- or 420-MHz QSO, and 3 points for each 1215-MHz and above QSO. Crossband QSOs do not count.

Multipliers count once per band: each ARRL section in the contiguous 48 states (63 max.), each Canadian province (max. 12), and each OXCC country (excluding W and VE).

REPORTING:

Entries must be postmarked no later than July 11th and sent to the ARRL Headquarters in Newington CT 06111. Official entry forms are available from the same address for an SASE. Usual ARRL disqualification rules apply. Usual awards to top scorers in each ARRL section, some limited to where significant effort or competition is evidenced. Multi-operator entries are not eligible for single-band awards.

SUMMER SMIRK PARTY
Starts: 0000 GMT June 16
Ends: 2400 GMT June 17

The contest is sponsored by the Six-Meter International Radio Klub (SMIRK). No crossband contacts, multi-operators, or partial contacts are allowed. Check logs or dupe sheets are not needed.

EXCHANGE:

SMIRK number and ARRL section, foreign state, province, prefecture, or country. Count ARRL sections in the 48 US states only; KH6 and KL7 count as countries. Washington DC counts as a section as well. Canadians count as provinces; all others count as states, provinces, prefectures, or countries.

SCORING:

Count 2 points for each SMIRK contact, 1 point for non-SMIRK QSOs. Add QSO points and multiply by number of ARRL sections, foreign states, provinces, prefectures, or countries worked for final score.

AWARDS:

Certificates for high-scoring SMIRK in two divisions: US/Canada and foreign. Certificates for high score in each ARRL section and foreign state, province, prefecture, or country.

ENTRIES:

Entries must be submitted on the fall, 1981, edition of the official SMIRK log. Single copies are available for an SASE and photocopies may be used. Send log requests and entries postmarked by July 8th to: Mark S. Anderson WB5NPK, 8932 Saddle Trail, San Antonio TX 78255.

ARRL FIELD DAY
Starts: 1800 GMT June 23
Ends: 2100 GMT June 24

Sponsored by the ARRL, the contest is open to all amateurs in the ARRL Field Organization plus Yukon and NWT. Foreign stations may be contacted for credit but are not eligible to compete. The object is to work as many stations as possible under less-than-ideal conditions. Operating times are limited depending on your operating class; check rules below.

Entry categories are classified by the maximum number of simultaneous transmitted signals followed by the designation of the nature of the individual or group participation. Below 30 MHz, a transmitter must remain on a particular band for at least 15 minutes once used for a contact on that band. During this 15-minute period, the transmitter is considered to be transmitting a signal (even if it is not) for purposes of determining transmitter class. Switching devices are prohibited.

Class A consists of club and non-club portable stations specifically set up for Field Day. Such stations must be located in places that are not regular station locations and must use no facilities installed for permanent station use nor any structures installed permanently for FD use. Stations must be operated under one callsign and under the control of a single licensee or trustee for each entry. All equipment (including antennas) must lie within a 300-meter circle. All contacts must be made with transmitters and receivers operating independent of commercial mains. Entrants who, for any reason, operate a transmitter or receiver from commercial mains for any contacts will be listed separately at the end of their class.

Any Class-A group whose entry classification is two or more transmitters (non-Novice) may also use one Novice/Technician operating position (Novice bands only) without changing its basic entry classification. This station (including antennas) should be set up and operated by Novice and Technician licensees and should use the callsign of one of these operators.

Class B consists of non-club portable stations set up and operated by not more than two licensed amateurs. Other provisions are the same as for Class A.

Class C consists of mobile stations in vehicles capable of operation while in motion and normally operated in this manner, including antenna. This includes maritime and aeronautical mobiles.

Class D consists of stations operating from permanent or licensed station locations using commercial power. This group of stations may only count contacts made with Class A, B, C, and E Field-Day groups for points.

Class-E stations are the same as Class D except they use emergency power for transmitters and receivers. They can work stations in all classes.

Operators participating in FD may not contact for point credit the FD portable station of a group with which they participate. Any station used to contact one or more FD stations may not be used under any other call during the FD period, except for family stations.

Each phone and each CW segment is considered as a separate band. All voice contacts are equivalent, and RTTY/ASCII is counted as CW. A station may be worked once on each band—crossband contacts are not allowed. The use of more than one transmitter at the same time in a single band is prohibited, except that a Novice/Technician position may operate on any Novice band segment at any time. No repeater contacts.

EXCHANGE:

Stations in any ARRL section send Field-Day operating class and ARRL section. A four-transmitter station in NJ would send "4A NJ". Foreign stations send RS(T) and QTH.

SCORING:

Scores are based on the number of valid contact points times the multiplier corresponding to the highest power used at any time during the FD period, plus bonus points. Phone contacts are one point each, CW counts two points each. Power multipliers are: 5 for using a dc input power of 10 W (20 W PEP) or less (or 5-W dc output/10-W PEP output) and if using a power source other than commercial mains or motor-driven generator; 2 for using a dc input power of 200 W or less on CW and 400 W PEP or less on SSB; 1 for using anything higher.

Batteries may be charged while in use for Class-C entries only. For other classes, batteries charged during the FD period must be charged from a power source independent of the commercial mains.

Bonus points will be added to the score (after the multiplier is applied) to determine the final score. Only Class-A and Class-B stations are eligible for bonuses:

CALENDAR

Jun 9–11	ARRL VHF QSO Party
Jun 16–17	Summer SMIRK Party
Jun 23–24	ARRL Field Day
Jul 1	Canada Day Contest
Jul 7–8	YV Independence Worldwide Contest—SSB
Jul 13–15	A5 International SSTV-DX Contest
Jul 14–15	IARU Radiosport Championship
Jul 28–29	YV Independence Worldwide Contest—CW
Aug 4–5	ARRL UHF Contest
Aug 11–12	New Jersey QSO Party
Aug 18–19	SARTG Worldwide RTTY Contest
Aug 24–27	A5 North American UHF FSTV-DX Contest
Sep 8–9	ARRL VHF QSO Party
Sep 15–17	Washington State QSO Party
Sep 22–23	Late Summer QRP CW Activity Weekend
Oct 6–7	ARRL QSO Party—CW
Oct 13–14	ARRL QSO Party—Phone
Oct 20–21	Jamboree On the Air
Nov 3–4	ARRL Sweepstakes—CW
Nov 17–18	ARRL Sweepstakes—Phone
Dec 1–2	ARRL 160-Meter Contest
Dec 8–9	ARRL 10-Meter Contest
Dec 28–Jan 1	QRP Winter Sports—CW
Dec 30	Canada Contest

1) *100% Emergency* Power—100 points per transmitter for 100% emergency power. All equipment and facilities at the FD site must be operated from a source independent of the commercial mains.

2) *Public Relations*—100 points for public relations. Publicity must be obtained or a bona fide attempt to obtain publicity must be made, or operation must be conducted from a public place (such as a shopping center). Evidence must be submitted in the form of a clipping, a memo from a BC/TV station that publicity was given, or a copy of material that was sent to news media for publicity purposes.

3) *Message Origination*—100 points for origination of a message by the club president or other FD leader, addressed to the SM or SEC, stating the club name (or non-club group), number of operators, field location, and number or ARES members participating. The message must be transmitted during the FD period and a fully-serviced copy of it must be included with the FD report. The message must be in standard ARRL message form or no credit will be given.

4) *Message Reply*—10 points for each message received and relayed during the FD period, up to a maximum of 100 points. Copies of each message, property serviced, must be included with the FD report.

5) *Satellite QSO*—100 points can be earned by completing at least one QSO via satellite during the FD period. The repeater provision is waived for satellite QSOs and a satellite station does not count as an additional transmitter. Show satellite QSOs as a separate band on the summary sheet.

6) *Natural Power*—FD groups making a minimum of 5 QSOs without using power from commercial mains or petroleum derivatives can earn 100 points. This alternative power source also includes batteries charged by natural means (not dry cells). The natural-power station counts as an additional transmitter. If you do not want to change your entry class, take one of your other transmitters off the air while making the natural-power QSOs. A separate list of natural-power QSOs should be enclosed with your entry.

7) *W1AW Message*—A bonus of 100 points will be earned by copying a special ARRL FD bulletin sent over W1AW on its regularly announced frequencies just before and during FD. This message can be received directly from W1AW or by any relay method. An accurate copy of the received message should be included in your FD report.

REPORTING:

Entries must be postmarked by July 24th; no late entries can be accepted. A complete entry consists of a summary sheet and a list of stations worked on each band/mode during FD, plus bonus proof. The list of stations worked on each band or mode may take the form of official ARRL dupe sheets or an alphanumeric listing of callsigns worked per band and mode. This list may be computer-generated. Incomplete or illegible entries will be classified as check logs. A copy of FD logs should be kept by your FD group but should not be sent in unless specifically requested by the ARRL. Normal ARRL disqualifications rules apply.

All entries and requests for official forms should be addressed to: ARRL, Newington CT 06111. Include a 9" by 12" self-addressed envelope with 3-oz. postage for a complete Field-Day entry package.

North Florida Amateur Radio Society
Balanced Modulator W4IZ
JACKSONVILLE, FLORIDA ·ARRL·

NEWSLETTER OF THE MONTH

The North Florida Amateur Radio Society's *Balanced Modulator* is consistently one of the best club publications in the nation. In addition to lively editorial commentary and very comprehensive ham news coverage, *BM* also includes Pete Nissen W4PTT's well-done "DX and Other Stuff" column. Two other features—unique and valuable—began with the March issue: a NOFARS member business and services directory and NOFARS assistance and advice network listings. Congratulations, President Billy Williams N4UF and all NOFARS members!

To enter your club's newsletter in *73's* Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

CANADA DAY CONTEST
Starts: 0000 GMT July 1
Ends: 2400 GMT July 1

Sponsored by the Canadian Amateur Radio Federation (CARF), the contest is open to all amateurs and everybody works everybody. Entry classes include single-operator, all bands; single-operator, single band; and multi-operator, all bands. There are also separate single-operator QRP (5-W output) classes for all bands and single band.

Use all bands from 160 to 2 meters on CW and phone combined. All contacts with amateur stations are valid. Stations may be worked twice on each band, once on CW and once on phone. No crossmode contacts and no CW contacts in the phone bands are allowed.

EXCHANGE:

Signal report and consecutive serial number starting with 001. VE1 stations should also send their province (NS, NB, PEI). Do not use a separate series of numbers on each band.

SCORING:

Score 10 points for each contact with Canada, 1 point for contacts with others. VE∅ counts as Canada. Score 10 points for each contact with any CARF official station using the suffix TCA or VCA. Multipliers are the number of Canadian provinces/territories worked on each band on each mode (12 provinces/territories x 2 modes for a maximum of 192 possible multipliers). Contacts with stations outside Canada count for points but not multipliers.

FREQUENCIES:

1810, 1840, 3525, 3770, 7025, 7070, 14025, 14150, 21025, 21250, 28025, 28500, 50.040, 50.110, 144.090, 146.52. Suggest phone on the even hours (GMT), CW on the odd hours (GMT). Since this is a Canadian-sponsored contest, remember to stay within the legal frequencies for your country!

AWARDS:

Certificates will be awarded to the highest score in each category in each province/territory, US call area, and DX country. If scores are close, second- and third-place certificates will be awarded. Additionally, several trophies will be awarded to some top scorers courtesy of sponsors.

ENTRIES:

A valid entry must contain log sheets, dupe sheets, a cover sheet showing claimed QSOs, QSO points, a list of multipliers, and a calculation of final claimed score. Cover sheets and multiplier checklists are available. Entries should be mailed within one month of the contest, with your comments, to: CARF, PO Box 2172, Stn D, Ottawa, Ontario, K1P 5W4 Canada.

Results will be published in *TCA*, the Canadian amateur magazine. Non-subscribers may include an SASE for a copy of the results.

THE NCDXF 20-METER BEACON NETWORK

Have you been listening on 14100 as I suggested last month? If not, tune your receiver to that frequency as you read the column this time.

What do you hear under all that interference? A strange pattern of CW signals and long dashes from stations all over the world. This is the 20-meter beacon network, constructed by the Northern California DX Foundation (NCDXF).

This network consists of eight automated beacons scattered around the globe. Each beacon transmits on a strict time sequence (see Table 1).

The beacons provide current information on the state of the ionosphere and on radio propagation to various parts of the world, all in less than ten minutes! Let's have a closer look at this network to see how we can use it to best advantage.

The Beacons

Each of the beacons consists of a power supply and controller, a Kenwood TS-130 transmitter, and an omnidirectional antenna. The controller features a quartz-clock accuracy of one part in 10,000,000, a microprocessor to generate the beacon CW identification, and a switching network to reduce the power of the transmitter in 10-dB steps.

0000	4U1UN	United Nations, New York City
0001	W6WX/B	Stanford University, Palo Alto, California
0002	KH6O/B	Northeastern Oahu Island, Hawaii
0003	JA2IGY/B	Mt. Asama, Japan
0004	4X6TU/B	Tel Aviv University, Israel
0005	OH2B	Helsinki Technical University, Finland
0006	CT3B	Madeira Island, Africa
0007	ZS6DN/B	Transvaal, South Africa
0008-9		(silent)

Table 1.

This power reduction is one of the most fascinating aspects of the beacon system. During the 58 seconds that each beacon transmits, its output power drops by a factor of 10 every ten seconds (see Table 2). The final 9-second-long dash, preceded by four dits, is sent at the power level of only 0.1 Watts! And yet you can hear the 0.1-Watt level from several of the beacons.

A Kenwood TS-130 transceiver and a quad antenna comprise the rest of the beacon. The Kenwood transceivers have held up very well under the continuous-duty operation of the beacons; no beacon has ever been off the air for transceiver problems. The antenna is a turnstile made of two quad loops at right angles to each other. This antenna produces an antenna pattern practically omnidirectional in the horizontal plane, and with the pattern favoring low-angle radiation in the vertical plane. Each side of the quad loops is 17' 11" long.

Each beacon package, including antenna, costs about $1300. The Northern California DX Foundation is picking up the tab for this entire project, including the eight beacons in place, and future beacons (see below).

Behind the Beacons

The network is the brainchild of Stanford Research Institute scientist Dr. Mike Villard W6QYT, who has had a long time interest in worldwide radio propagation. With the support of the Northern California DX Foundation and the active assistance of several San Francisco Bay area amateurs, the network began to take shape in the late 70s.

Dave Lesson W6QHS took some time off from his multimillion-dollar Silicon Valley company to design the necessary hardware. His contribution included the overall design of the network along with the details of the switching system to change the power level of the transmitter. Jack Curtis K6KU designed the clock and microprocessor which control the switching circuitry and generate the code identification. Jack has had considerable experience in this field; he's the Curtis of the Curtis keyer and code-teacher line! And finally Cam Pierce K6RU assembled much

of the actual hardware and prepared the actual beacon packages. NCDXF President Jack Troster W6ISQ provided (and is continuing to provide) overall coordination and international supervision of the network.

And continuing on duty on a daily basis is Al Lotze W6RQ, who coordinates the regular observers of the beacons and compiles the reports (see below).

Among the other persons vital to the success of the beacon network are the individual beacon "custodians." These are the hams and groups, carefully selected by the NCDXF, to set up and operate the beacons. In many cases the beacons are under the auspices of a university.

The beacons network grew slowly; the first beacon, WB6ZNL, went on the air at the end of 1979. WB6ZNL has changed callsigns a couple of times since then and is now W6WX/B at Stanford University in Palo Alto, California.

That first beacon required more than hardware. The beacon transmits what is technically an unattended A0 emission, which is not permitted under Federal Communications Commission (FCC) amateur rules. So the Foundation had to request a special waiver of the FCC rules to allow the beacon to begin transmitting. The same held true for the Hawaiian beacon, KH6O/B, under the watchful eye of Bob Jones KH6O. Perry Williams W1UED of the American Radio Relay League's Washington DC office was instrumental in obtaining the necessary waivers.

On the other hand, the other beacon located "within" the United States required no such special permission. The 4U1UN beacon sits on UN territory in New York City and thus falls under the rules of the International Telecommunication Union, which permits the beacon.

The situation was even more complicated in Japan. Japanese amateur regulations had neither rules nor standards about beacons. In order to get permission to establish the beacon in Japan, JA hams had to work with the licensing authority to *write entirely new regulations* for beacon standards.

Perseverance prevailed, however, and by early 1983, all eight beacons were on the air. The beacons' record of dependability has been very good. Some of the beacons associated with universities must occasionally shut down to avoid disturbing delicate experiments. But there has been little unscheduled "downtime" on the system. The only recurring problem was a single resistor in the power supply, since replaced. The network's on-time record is a great tribute to the design, engineering, and maintenance of the beacons.

The very dependability of the beacons has led to one slight problem: the clocks of the beacons slowly drift, and the beacons start to overlap. The clocks in the beacons are accurate to about one part in ten million, or about one half second a month. Since the beacons have required no maintenance other than resetting the clocks, their timers have occasionally drifted enough to overlap. So if you want to set your watch by a radio signal, tune to WWV (see this column, April, 1984).

Al Lotze W6RQ coordinates the beacon reports from this modest station.

Using the Beacons

These beacons, both individually and as a network, provide many benefits to the DXer. Besides the obvious use of determining band openings, hams can use this system to check antennas, compare rigs, calibrate their S-meters, and compute antenna patterns. Let's look at some of these possibilities.

Since the beacons put out the same power day after day, you can use the beacon network to monitor the condition of your station. By logging the signal strengths of the different beacons at various times of the day, you can build a reference point for changes in your station. For example, if your coaxial cable begins to deteriorate, you might notice a gradual reduction in the signal strengths of the beacons. Similarly, changes in switches, filters, and rigs can be compared to the references you establish by consistently monitoring these beacons.

Such consistent monitoring is important if you want to eliminate the vagaries of propagation from your considerations. You don't want to rip out a new antenna just because you tested it on the day of a solar flare!

You can also use the beacon network to check the low-angle radiation pattern of your antenna. Since most of the beacons are a goodly distance from your station, most of the radiation you hear from them will arrive at your antenna at the low angle characteristic of DX communications. By swinging your antenna during the long, 9-second dash of each beacon, you can note relative signal strengths from the front and the back of the antenna. You may find the ratio between these figures quite different from that advertised by the antenna manufacturer!

Of even greater interest to the DXer will be the angle of minimal reception on the antenna. Beam or directional antennas *do* increase the signal strength in a given direction, but they also serve an even more valuable service by reducing the signal strengths of stations lying in other directions. The ability to "null out" or nullify an interfering station is at least as important as the increased signal strength given by the directional antenna.

So the DXer wants to know where to point the beam to *minimize* reception of the offending signal. Knowing where the nulls are in your antenna pattern is as important as knowing the front-to-back ratio.

Another immediate benefit of the NCDXF beacon network is its use for S-meter calibration. The power level of each beacon decreases by a factor of 10, or by 10 dB, each 10 seconds. You can calibrate your S-meter by carefully watching the meter during these power changes. Your meter reading should drop by 10 dB (a little less than 2 S-units) each step in power reduction.

If your receiver doesn't track this way, you might want to produce a calibration chart to reflect the *actual* power levels.

And, of course, the beacons tell what is happening with radio propagation *right now*. How many beacons can you hear? How strong are their signals? How do these signal strengths compare to other days when the propagation was good, medium, or fair?

Beacon report coordinator Al Lotze W6RQ feels that the beacons present a more accurate picture of present amateur-radio propagation than do the WWV bulletins or the forecasts by charts or tables in the amateur-radio magazines. "Those charts don't include the A index" (see this column, last month). "Their Maximum Usable Frequency charts only reflect solar flux. But I have found the A index a more telling indicator of present propagation," Al explains.

How can the DXers best use this propagation information? First, beacon receptions might suggest good possibilities for directional CQs. If you *know* the band is open from your location to Eastern Africa (CT3) you might try a CQ directed toward that area. DX stations are much more likely to answer a directional or specific CQ than a more general "CQ DX."

With regular listening, you can learn a great deal about radio propagation from your station to other parts of the world. When does the long or skew path open up to Europe, or to Japan? In which direction does it peak? What are the differences in signal strength as dawn or sunset passes? When is the best time to get up in the middle of the night to work that rare DXpedition?

The avid student of radio propagation can use the beacon network to obtain even more information. What is the relationship between the WWV flux numbers and propagation from your location? Do the signal strengths of the polar and the equatorial paths change at the same time, or in different patterns? The possibilities are endless.

Making Beacon Reports

If you are serious about listening to the beacons, you might want to share your observations and ideas with others of similar persuasion. Beacon report coordinator Al Lotze W6RQ (see photo) collects the reports from regular and irregular reporters from all over the world.

As of last winter, Al had received more than 250 reports from every continent. The reports have ranged from a simple, "I heard your beacon yesterday," to complex and detailed analyses and theories of propagation. The most dedicated are several European scientists. At least one Belgian amateur sends in a full page of comments and ideas every month! Other regular reporters include engineers and shortwave listeners (SWLs). The list of reporters shows that you don't need fancy equipment to monitor the beacon networks; Al has received a report from a Czechoslovakian amateur who used a direct-conversion receiver!

Amateurs and others interested in becoming regular monitors and reporters for the beacon network should contact Al Lotze W6RQ, 46 Cragmont Ave., San Francisco CA 94116-1306. Al prefers the official reporting form but will acknowledge all reports with a beacon network QSL. You don't have to hear all eight beacons to send in a report, but you should listen to the network several times at different hours and note any patterns.

The informal collection of regular beacon watchers spends more time listening than they do transmitting (like any good DXer!) but they do occasionally key up their rigs during the 2-minute "break" at the end of each sequence of bulletins. If you listen closely during this "off" time, you might hear a beacon observer send "All 8 hrd de W6RQ," or a similar message.

Al Lotze W6RQ Report Coordinator

Al Lotze is an excellent man for the job of coordinating these beacon reports. In his 53 years as an amateur, Al (see photo) has amassed 282 countries on CW. His station today is as elaborate as any he has used in more than 50 years, but you may note the absence of such items as an antenna switch, antenna rotor, or amplifier.

Al runs Kenwood barefoot through a Johnson matchbox to a G5RV antenna on the roof of his home, high on a hill above San Francisco. Al claims his DX success comes from his suffix. "There are more stations with the suffix RQ in the DXCC listing than any other suffix," Al notes with a twinkle in his eye. Despite this simple station setup, Al has frequently heard all eight beacons in one cycle, especially around local sunset when the A index is under 10.

A long-time follower of radio propagation, Al monitors WWV propagation bulletins daily. Weather permitting, Al also sets up his telescope every day to chart the size and position of each sunspot. His charts appear in *QRZ DX* every week.

Al maintains lively communications with his far-flung collection of regular beacon reporters. With a working command of French, Spanish, and German, Al attempts to respond to most reporters in their native languages. With daily charts of the sun's surface for years, careful graphing of the WWV propagation information, and more than 50 years of amateur experience, Al holds his own among

Power Level	Message
100 Watts	QST de (callsign)
100 Watts	. __________ (9-second dash)
10 Watts	.. __________ (9-second dash)
1 Watt	... __________ (9-second dash)
0.1 Watt	.... __________ (9-second dash)
100 Watts	SK (callsign)

The entire sequence takes about 58 seconds, at about 20 words per minute.

Table 2. Beacon transmission pattern.

he professional propagation experts with whom he corresponds.

Results of Beacon Network

The information from the beacon watchers continues to pour into Al's mailbox, so it will be years before any statistically valid results come from this network. But Al has noted several trends which became evident very quickly. The first, and perhaps most interesting pattern, is how the low-power signals can be heard clearly. QRP enthusiasts have been saying this for years: you don't need power to make DX contacts. Listen for yourself to hear how often you can hear the 0.1-Watt level of the beacons. Makes one want to ban all amplifiers.

Another interesting conclusion suggested by the beacon network is that the traditional explanation of how radio waves travel more than 2500 miles is wrong. The textbooks claim that signals which travel farther than 2500 miles must bounce back and forth between the Earth's surface and the ionosphere several times: multi-hop propagation. However, much of the signal is lost in each bounce. The mathematics of this theory suggest that the 0.1-Watt beacon would never be heard if the signal were to propagate via multi-hop propagation. So the radio signal must get from there to here in some other way. We may never know exactly how the signal travels, but we do know that the traditional multi-hop theory has holes in it.

Al has also noticed that the A index seems to be closely related to beacon receptions. The only times he has heard all eight beacons at the same time has been when the A index is very low, 10 or less. He notes that traditional propagation forecasting, including the charts and tables in the amateur press, do not include the A index in their calculations. Thus even when the solar flux might be high enough for good radio, the high A index may prevent good propagation.

The Future of the Network

What's ahead for the NCDXF 20-meter-beacon network? The two "off" minutes certainly suggest that at least two more beacons will be forthcoming soon. In the works for this summer is a beacon on the northern coast of South America, in Colombia. Another possibility for a tenth beacon is the southern end of the South American continent, but the real propagation hounds prefer a Western Australia location, VK6.

The beacon network doesn't have to stop growing at ten. Built into the control circuitry is the ability to switch to 20 beacons per ten-minute cycle. One can imagine a few years from now being able to get exact propagation information to 20 different locations around the world in only 10 minutes!

These beacons and many other DX activities, including major DXpeditions, are sponsored by the Northern California DX Foundation. Membership in the NCDXF is $10.00 and includes a handsome membership certificate. Contact NCDXF at PO Box 2368, Stanford CA 94305.

And please, for the sake of all of those hams listening to the beacons, stay off 14100 kHz!

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

ELMER OF THE YEAR

F. Wendell Tietsworth W2SUE was chosen as QCWA's Northern New Jersey Chapter's 1983 Elmer of the Year from a field of nominees by a committee which included such prominent local amateurs as Joseph Paintsr W2BHM, head of the W2 QSL Bureau, and William Mumford W2CU.

W2SUE has been teaching ham-radio courses since 1985. He currently teaches Novice classes at the Nutley NJ Red Cross Building and is active in Army Mars as AAR2JP.

SOUTH EAST QUEENSLAND TELETYPE GROUP AWARD

This award is open to all transmitting and listening amateurs who gain award points in the following manner: Australian amateurs must score 5 points and overseas amateurs must score 3 points.

(a) To qualify, a station must, where possible, copy the official station of the South East Queensland Teletype Group, VK4TTY, during a news broadcast and, in the case of a transmitting amateur, participate in the callback (2 award points). A portion of the printout of the news broadcast together with the date, time, frequency, and broadcast number are to accompany the request for the award.

(b) Additionally, a transmitting amateur must work three member stations of the SEQTQ on RTTY (1 point each). Log extracts and/or printouts are to be included with the award application, and each member station may be counted only once towards the award.

(c) Listening amateurs should, in lieu of (b), forward log extracts and/or printouts of three contacts involving different member stations of the SEQTG (1 point each).

Applicants for the award should forward the above information together with one dollar Australian or 5 IRCs, to cover postage and printing costs, to the Secretary, SEQTG, PO Box 274, Sunnybank, Queensland 4109, Australia.

WORKED ALL BERMUDA

The WAB Award is issued to amateurs throughout the world by the Radio Society of Bermuda. To qualify, applicants must submit proof of having worked a minimum of nine (9) parishes in Bermuda: Sandys, Southampton, Warwick, Paget, Pembroke, Devonshire, Smith's, Hamilton, and St. George's.

The award is an antique map of Bermuda (20" × 23") suitably inscribed with the recipient's name and callsign and signed by His Excellency the Governor of Bermuda.

The award is not available to stations who worked Bermuda via mobile including maritime or aeronautical. No band or mode endorsements are available. Only one mobile or portable from within Bermuda may be used in making claimed contacts on your applications.

QSL cards are required as proof of contact and they must be sent to the awards manager with sufficient postage for their safe return. The Bermuda Award is issued free of charge! Submit your applications to: Award Manager, PO Box 275, Hamilton 5, Bermuda.

WORKED BROWARD COUNTY CITIES

The Broward Amateur Radio Club, Inc., sponsors the new WBCC award, available to licensed amateurs who submit proof of two-way contact as follows:

(a) Residents of Broward, Colliers, Dade, Glades, Hendry, Lee, Martin, Monroe, or Palm Beach counties must work all 29 of the cities listed below.

(b) All other amateurs must work 15 of the 29 cities within Broward county.

To be valid, all contacts must be verified by at least two fellow amateurs and application must show all logbook information as well as the OTH of the station worked.

To apply, mail your application with $1.00 (US funds) and two first-class stamps (DX stations send 10 IRCs) to: BARC Award Manager, WD4RAF, 1921 NW 41st Street, Oakland Park FL 33309.

Qualifying city contacts include: Coconut Creek, Cooper City, Coral Springs, Dania, Davie, Deerfield Beach, Fort Lauderdale, Hacienda Village, Hallandale, Hillsboro Beach, Hollywood, Lauderdale-by-the-Sea, Lauderdale Lakes, Lauderhill, Lazy Lake, Lighthouse Point, Margate, Miramar, North Lauderdale, Oakland Park, Parkland, Pembroke Park, Pembroke Pines, Plantation, Pompano Beach, Sea Ranch Lakes, Sunrise, Tamarac, and Wilton Manors.

WORKED ALL ASIAN AWARD

The WAAA program requires the applicant to work other amateurs in the member countries of the Association of Southeast Asian Nations. Work 5 Philippine contacts, 1 Malaysian contact, 2 Indonesian contacts, 1 in Thailand, and 1 station in Singapore. Special endorsements will be given for All-Phone, All-CW, Single-Band, and Five-Band contacts.

Have your list of contacts verified by at least two radio-club officials and be sure all contacts were made after January 1, 1970, to be valid. Forward appropriate logbook information in your application along with $4.00 (US funds only, no IRCs) to the Award Manager: Edwin Zambrano DU1EFZ, PO Box AC-166, Quezon City 3001, Philippines.

WORKED ALL DU AWARD

This award is available to all licensed amateurs who can show proof of having contacted at least one station from each of the call areas in the Republic of the Philippines (DU1 to DU9, except DU5).

Contacts may be made on any band or mode and special endorsements will be issued upon request for All-Phone, All-CW, Single-Band, or Five-Band accomplishments.

Contacts for the DU Award must be made on or after January 1, 1970. To apply, forward a list of contacts which have been verified by two officers of a radio organization. Your application must show all logbook information for each contact. Send the list and $4.00 (US funds only—no IRCs, please!) to: Edwin Zambrano DU1EFZ, PO Box AC-166, Quezon City 3001, Philippines.

VK1 ACHIEVEMENT AWARD

The A.C.T. Division of the Wireless Institute of Australia is proud to announce the creation of its newest award, the VK1 Achievement Award. This award has the aim of increasing interest in the VK1 prefix and in promoting Canberra and Australia internationally.

As there are only 300 VK1 licensees, the award will not be an easy one to achieve, particularly on some bands and modes. The VK1 Award is available to licensed amateurs throughout the world. To qualify, stations within Australia must work 20 stations in VK1 land on HF and on VHF. Stations outside Australia must work a minimum of 10 VK1 stations for the HF segment of the award.

To apply, submit your list of contacts, including the GMT time and date worked, the band and mode of operation, and any reports or ciphers exchanged. To be valid, all contacts must be made on or after January 1, 1978. Endorsements may be given at the time application is made. Five IRCs or $2.00 in Australian currency cover the cost of the award and should be sent to the Award Manager, c/o WIA, PO Box 46, Canberra A.C.T. 2600, Australia.

By the way, the VK1 Award is also made available to shortwave listening stations on a heard basis. QSL confirmation is required.

WORKED ALL FORGOTTONIA

Announcing the awards program sponsored by LEARC, the Lamoine Emergency Amateur Radio Club of Macomb, Illinois. The Worked Forgottonia Award is issued to amateurs who confirm contact with three (3) licensed amateurs of Forgottonia. The Worked All Forgottonia Award is issued to operators confirming contact with at least one amateur in each of the sixteen counties of Forgottonia

What is Forgottonia? It is the 51st state! It consists of the following counties (formerly west central Illinois): Adams, Brown, Calhoun, Cass, Fulton, Greene, Hancock, Henderson, Knox, McDonough, Mercer, Morgan, Pike, Schuyler, Scott, and Warren.

All contacts must be made after June 28, 1980, to be valid From the letter we received from the club, the award evidently is issued at no charge since no remittance was mentioned. Forward your list of verified contacts and a 9" × 12" SASE to the attention of AG9Y, c/o LEARC, 1224 Maple Avenue, Macomb IL 61455.

WAT AWARD

The Cabin Fever Radio Club of Tok, Alaska, offers a certificate for contacting three amateurs in Tok. There are no band or mode restrictions. However, all contacts must be made after December 15, 1980, to be considered valid.

To apply, prepare a list of contacts in order by callsign. Include the name of the station operator, the date and time worked in GMT, and the mode and band of operation. QSLs not required. Amateurs located in Tok include AL7O, AL7BO, AL7BV, and WL7APG.

Send your application with $2.00 or 10 IRCs to: Cabin Fever Radio Club, Box 451, Tok AK 99780.

BASEBALL SPECIAL

The Lewis-Clark ARC will operate W7VJD Friday, June 1, from 0200Z until the last game has been played, Saturday, June 2, from 1600Z until last game played, and Sunday, June 3, from 1600Z until last

game played, during the NAIA World's Collegiate Baseball Tournament, on the campus of Lewis-Clark State College.

Frequencies: 14.270, 7.235, 3.940 ± QRM phone; 14.130, 7.125 ± QRM CW.

Please send SASE for QSL via Dan Wenstrom WB7BQV, 630 Stewart, Lewiston ID 83501.

EIGHTH STREET FESTIVAL

The Madison County Amateur Radio Club will operate the club station, W9VCF, portable from the historic Eighth Street Festival in Anderson, Indiana, on June 8 and 9, 1984. A special certificate will be offered to persons contacting the club station during the festival or any club member during the month of June. Suggested operating frequencies are: 28.785, 21.400, 14.340, 7.290, and 3.990 MHz.

Send log information and a dollar donation to: Madison County ARC, c/o Frank M. Dick WA9JWL, 921 Isabella Drive, Anderson IN 46013.

SPECIAL-EVENTS STATION 7SK0AC

The Swedish Telecommunications Administration has given permission to the Swedish Radio Amateur Radio Club to use the special-events prefix 7SK in connection with operations from the club station, SK0AC, during the annual conference of the European DX Council in Stockholm, June 8-10, 1984. The EDXC is the umbrella organization of the shortwave radio listening clubs in Europe. The annual conference has become *the* meeting place in Europe for international broadcasters who are actively involved in programming or the technical side of international radio and the representatives of the listeners' clubs, which can now boast more than thirty thousand members.

The 1984 conference is being hosted by Radio Sweden International and the Swedish DX Federation at the studios of RSI in Stockholm. 7SK9AC will be on the air during the conference, operated by members of the club and licensed amateurs among the conference participants. Among those who are expected to operate from the station are Victor Goonetilleke 4S7VK, Colin Richards 9M2FJO, Lars Rooth HV3SJ, Wolf Harranth OE1WHC, and Bernt Erfjord LA5TBA.

7SK0AC is expected to go on the air at about 1500 hours GMT on Friday, June 8, 1984. Operation will continue at various times during the conference on Saturday, June 9, and Sunday, June 10. Frequencies to be used during daylight hours are 14060 kHz (CW), 14320 kHz (SSB), 21060 kHz (CW), and 21350 kHz (SSB); and during hours of darkness, 3550 kHz (CW) and 3700 kHz (SSB).

There will also be some operation on the 2-meter band.

MECA

The Macomb Emergency Communications Association will have its second special event on the weekend of June 8-10. Operation will commence at 2200Z Friday, June 8, and continue around the clock to 2200Z Sunday, June 10, near the lower end of the General-class portion of each amateur band as propagation dictates. Modes of operation will be SSB and CW/RTTY on HF and FM phone on 146.07/.67. QSL to MECA, Box 488, Utica MI 48087 with a 9" × 12" SASE for certificate. DX stations need send only QSL

BROOKFIELD ZOO

The Chicago Suburban Radio Association will operate special-event radio station N9BAT from the Brookfield Zoo in celebration of its 50th anniversary. It is one of the largest zoos in the United States and was the first American zoo to exhibit animals in naturalistic displays behind moats instead of in cages. Its Tropic World is the largest zoo building in the world, housing African, Asian, and South American rain forests.

Operation will be June 9 and 10 from 1600Z-2400Z, using the phone frequencies of 7.250 and 14.250 MHz. A special full-color zoo QSL card will be available to all stations that reply with their QSL card and a #10 (business-size) SASE to: N9BAT Special Event, PO Box 383, Brookfield IL 60513.

KNOX COUNTY ARC

The Knox County Amateur Radio Club will have a special-event station on the air to commemorate Galesburg Railroad Days. Railroad Days is an annual event for Galesburg, Illinois, which pays tribute to the role of the Burlington Northern (formerly the CB & Q) and the Sante Fe Railroads in the development of the area.

The KCARC will have its special-event station on the air on Saturday and Sunday, June 9 and 10, 1984, from 1300Z 'til 2200Z. The station will operate on one of the following frequencies: 7.235, 14.280, 21.375, and 28.630 MHz, plus or minus QRM and depending on band conditions. The call of the station will be W9GFD. A special commemorative QSL card will be sent to any station contacted which sends an SASE to the Knox County ARC, Inc., W9GFD, 1894 Bluebird Drive, Galesburg IL 61401.

HELEN KELLER DAYS

The Muscle Shoals ARC will operate W4JNB from 1600-2100Z on June 29 and 30 and July 1, 1984, from Spring Park, Tuscumbia, Alabama, in celebration of Helen Keller Festival Days. Phone frequencies are 7270-7290 and 14,280-14.295. For an 8" × 10" certificate, send an SASE (4" × 10" envelope) to Box 2745, Muscle Shoals AL 35862. Talk-in on two meters, 146.01/.61.

TOM SAWYER DAYS

The Hannibal Amateur Radio Club, Inc., will issue a fourth annual special certificate from the National Tom Sawyer Days celebration in Mark Twain's boyhood home town, Hannibal, Missouri, on Saturday, June 30 and Sunday, July 1, 1984. Hours: 1500-2100 UTC both days. Frequencies: phone 7.245, 14.290, 21.400, 28.770; and CW 7.125 and 21.125 MHz. Help us celebrate!

To receive the certificate, send a large (8 × 10) SASE and your personal QSL card confirming the contact to Hannibal Amateur Radio Club, Inc., W0KEM, 2108 Orchard Avenue, Hannibal MO 63401.

For further information, call Tony McUmber, 2108 Orchard Avenue, Hannibal MO 63401; (314)-221-6199.

ANNIE OAKLEY DAYS

W8UMD, the Treaty City ARA, will operate the Annie Oakley special-event station from 1400Z July 28 to 0200Z July 29, and 1400Z to 2200Z July 29. Frequencies will be 3910 kHz, 7235 kHz, and 14285 kHz. Send 9" × 12" SASE for unfolded certificate; otherwise send #10 SASE to TCARA, PO Box 91, Greenville OH 45331.

LETTERS

YES, IT WAS

Was that the same Ishmod Kaduk, the great explorer, who found the extension of Lake Michigan into Montana?

Roger Coppock
Bradview IL

OH YES HE WAS

Ishmod may not have been a fool, but I read up to p. 224 before I realized it was April!

Harry Church W0KXP
Lebanon IL

ISHMOD FOOLED AGAIN

The article on Ishmod's Journal (*73*, April, 1984) is one of the finest exposés on the potential perils of the DXpedition ever written. Reading it positively started my heart pounding with the desire to go rent an old Argentine aircraft carrier, hire a crew of Lascars and Dacoits, and get out among 'em. There is, however, a problem with the map you printed and the geography of the DXpedition in general. Some of my irregular friends will claim that the map you printed was originally made near Agra by Jonathan Small, Abdullah Khan, Mahomet Sing, and Dost Akbar, in the late 1870s. Others will attribute the map to a certain seagoing Bellman of the same period, citing these lines (see box).

Unfortunately, the map is a red herring. The true location of the island Ishmod and his friends found is, I am afraid, more sinister. The island where Ishmod and his friends landed can be none other than the dread R'lyeh which rises occasionally from the dark waters of the South Pacific and Indian Oceans. This island was first documented in English by H. P. Lovecraft, in 1928. It also is mentioned by the 15th century Arab scholar, Abdul Alhazred in his *Nacronomicon*. (Copies of the *Necronomicon* can be found in the Widener Library at Harvard and in the library crypt at Miskatonic University in Arkham, Massachusetts.) As further evidence, note the parallels between the log of the Brig *Emma* cited by Lovecraft and Ishmod's last printed words. Ishmod speaks of phenomena which defied the laws of physics. In the *Emma* log, we hear Johansen speak of geometry which was "abnormal, non-Euclidean, and loathsomely redolent of spheres and dimensions apart from ours." The partially complete reference to the rocks of the island also correlates with the Lovecraft account of unbelievable greenish stone blocks at R'lyeh.

From the above discussion, I think it clear that Ishmod and his friends have fallen prey to Cthulhu or some other of the star-born Old Ones. Only the other day on one of the Pacific DX nets I heard at about 35 wpm the horrid refrain, "Ph'nglui mglw'nafh Cthulhu R'lyeh wgah'nagl fhtagn." I fear for my fellow hams on other Pacific and Indian Ocean DXpeditions. They should take great care.

Henry P. Dowst KA6KNJ
Pacific Palisades CA

THANKS, 73

Just a short note to thank you for *73*. I have been a ham for only one year and have found *73* to be excellent reading with enough "beginner" projects to keep my interest high and my curiosity aroused.

I am not very adept at the technical aspects of amateur radio yet, but the projects in *73* are educating me and encouraging me to learn by doing.

Also, I think your editorials are terrific. It's been a long time since I've enjoyed reading someone's philosophy who has the courage to tell people the real facts of life; that is, "If you want something, go after it and earn it!" Thanks for reaffirming my belief in the spirit that once made this country great. I hope more people begin to re-apply this attitude.

Keep up the good work!

Gary Mills KB4ENG
Middlesboro KY

WET BATTERIES

Reference is made to your article, "Wet Battery Quiz."

First of all, smartass that I am, I'll admit I flunked the quiz. And I thought I knew it all, like the subtitle said.

I think I can clear up your author's comprehension on a couple of related points. He asks, "How could the concrete floor get through the acid-impervious case?" The time-honored advice to not so store a lead/acid battery is correct. Such storage frequently implies storage in an unheated garage or outbuilding. At night the temperature of the battery and floor both drop. In the morning, with the battery in intimate contact with the floor as a heat sink, warm moist air will cause condensation on the exterior case.

He is correct in stating that the acid path across the top of the battery will cause leakage.

He asks, "How come the acid inside the case does not cause current leakage?" Fair question. Here is my answer: First of all, think of a 2-volt cell as two "half-cells" with the gross part of the acid between them as a conductor and the acid in intimate contact with each cathode or anode as highly ionized and a component of the half-cell. With this concept it can be realized that an acid path across external terminals of greater potential than 2 volts will indeed cause a current to flow. And to make the case crystal clear to anyone still doubting, the highly-ionized interface between the conducting acid and the terminal "plates" out as a different colored chemical depending on the terminal polarity. White negative, and green positive.

I hope this clears up his understanding; it has mine. Thanks for a great article. I am an Old Car Nut, and between winter storage and summer heat and overcharging of these animals, what I have learned will be put to good use immediately.

William T. Tyrrel W2YKG
East Northport NY

SUPPORT YOUR NET

This is the first letter that I have written to you for publishing and I suppose that not all amateurs will agree, but I do know that the message needs to be gotten across. I suppose that the best title for this would be "An Open Letter to All Amateurs." I am not the best at spelling nor am I convinced that this will even be published, but I thought that I would at least make an attempt.

I have been a ham for around 8 years now and, like many hams, spend very little time on the air. An incident happened to me, though, that inspired me to write this letter. I had a QSO with a Mexican amateur station, and by coincidence he had a very good friend in a small town in Tennessee whom he had not been able to contact. Having checked into the Tennessee Net several times, I knew that I had a chance to contact his friend, so I offered to pass a message and see if I could arrange to get the two together on a 15- or 20-meter frequency. My Mexican amateur was very excited about this, although he didn't understand the net type of operation or its purpose. On March 8th, 1984, it just so happened that there was another ham in that *small* community in Tennessee who also was on the same phone exchange. Not only was I able to get the message across to my Mexican's friend, but also he was going to meet him on the air at the same time that I had arranged a schedule with him the following Saturday.

The moral of this story is, *please*, no matter how large a community you belong to, *support your local state net*! I had no idea that there was even another ham in that community, other than the one I needed to contact, but there was, and because he devoted thirty minutes of his time to be on the net, I was able to get two good friends together and back on track. Whether it is across the state, country, or world, the nets serve a very important purpose but are useless unless they have the support of the hams in the state and communities and counties of the state. It may be that you may never be called upon for traffic to your area, but what a blessing it is when you need an area and you can immediately get that area and pass the message.

I have heard many negative comments about the nets, how trivial they are, and that they serve no purpose, but believe me, one such use as I had and the net takes on a whole new meaning. I hate to hear the negative comments on how bad nets are conducted. It may be that a certain net control is bad or a certain net is inconsistent, but as amateurs we all owe it to ourselves to make an effort to learn proper net procedures—both CW and SSB. Some time, devote one night of the week to your state's net and get to know the net controls and the purpose of the nets, the time they meet, and most of all how you can contribute. I would like personally to charge all amateurs to help promote the best public service that we, as amateurs, can provide, and *get involved*. If you don't because of the lack of net procedures, write the editors of this publication or any ARRL official and I know that they will be glad to assist you. The message needs to get out, and an amateur's time cannot be put to better use than trying to help his fellow amateurs and the public by net participation.

Chattanooga TN

TWO-METER BEACON

The Lincoln Communications Society, Lincoln, Nebraska, has constructed a beacon transmitter to provide a signal for propagation studies and frequency reference. The beacon currently operates A1 (CW) on 144.055 MHz with an output power of 10 Watts to an omnidirectional antenna. The beacon location is in the northeast corner of grid square EN-10. The ID callsign is WB0QIY/B. Reception reports should be sent to me at the Lincoln Communications Society.

FAR OUT, FAROUT ARC!

On September 17, 1983, I worked Ruthann WD8BMK, who was operating special-event station WB8SMC in celebration of the 10th Anniversary of the Farout Amateur Radio Club located in Dayton, Ohio.

We exchanged the QSLs and on March 3, 1984, I received a beautiful personalized plaque as a token of the club's thanks for being a part of their celebration. Three QSLs had been drawn at random, and I was lucky to be one of them.

I would like to publicly thank the Farout Amateur Radio Club very much. A club like this that takes that extra step has to go *far*!! May they have 100 more anniversaries!

Richard C. Schott KA2PHQ
Spencerport NY

DX WORLD

Recently a program I wrote appeared in *73* (February, 1984), "Put the DX World On the Screen." I would like to thank all the many people that wrote me with their comments, suggestions, and their orders. The real pay in doing a project like this is the thanks that I receive from all my fellow hams; Lord knows the money isn't worth it. I hope that all the people who received my program were pleased with what they received.

As many people already know, I did a rewrite of the Prefix Locator program for the

---

He had brought a large map representing the sea,
Without the least vestige of land:
And the crew were much pleased when they found it to be
A map they could all understand.

"What's the good of Mercator's North Poles and Equators,
Tropics, Zones, and Meridian Lines?"
So the Bellman would cry: and the crew would reply
"They are merely conventional signs!"

"Other maps are such shapes with their islands and capes!
But we've got our brave Captain to thank"
(So the crew would protest) "that he brought us the best—
A perfect and absolute blank!"

From "A Nautical Ballad," Charles Carryl, 1841-1920.

Reimbursement of Out-of-Pocket Costs for Volunteer Administered Amateur Radio Examinations

AGENCY: Federal Communications Commission.

ACTION: Proposed rule.

SUMMARY: This document proposes to amend the rules to provide for reimbursement of out-of-pocket costs incurred by volunteer examiners and volunteer examiner coordinators in connection with amateur operator license examinations. Cost reimbursement is necessary for the volunteers in order for them to recover their prudently-incurred expenditures. The effect of this action is to propose rules allowing cost reimbursement.

DATES: Comments are due by April 16, 1984 and replies by May 1, 1984.

ADDRESS: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT: Maurice J. DePont, Private Radio Bureau, Washington, D.C. 20554.

Radio.

Notice of Proposed Rule Making

In the matter of reimbursement of out-of-pocket costs for volunteer administered amateur radio examinations; PR Docket No. 84-265, FCC 84-75.

Adopted: March 6, 1984.
Released: March 9, 1984.
By the Commission.

1. Notice of Proposed Rule Making in the above-captioned matter is hereby given.

2. The Federal Communications Commission Authorization Act of 1983 (Pub. L. 98-214; approved December 8, 1983) amended Section (4)(f)(4) of the Communications Act,[1] to provide for the reimbursement of out-of-pocket costs incurred by volunteer examiners and volunteer examiner coordinators in connection with the preparation, processing or administration of examinations for amateur station operator license. The American Radio Relay League, Inc. (ARRL) filed a Request for Agency Action on December 7, 1983, requesting that the Commission implement the legislation by amending the rules by Order as soon as possible. However, since this matter affects a large number of people (amateur licensees and applicants), we are providing for notice and comment.

3. Our proposed rules would allow both the volunteer examiner (VE) and the volunteer examiner coordinator (VEC) to be reimbursed. Each amateur radio examination, except the Novice Class,[2] is to be administered by three VE's. They may be reimbursed for the expenses they incur in administering the examination. Likewise, the VEC may be reimbursed for its preparation and processing of the examination. The total reimbursement from each examinee, however, may not exceed $4 for an examination. It could be less than that amount, depending upon the circumstances.

4. We do not propose to specify how the reimbursement fee is to be divided among the VEC's and the VE's. Both the VE's and VEC's may incur expenses. VEC's may be reimbursed for expenses that they incur in preparing and processing examinations. This could include the costs of printing, assembling and distributing the exams. In addition, a VEC may have other administrative costs since the VEC is responsible for keeping records on each examination that is given. Postage is another anticipated expense since the VEC must forward the applications of successful applicants to the Commission. There may also be costs for renting the premises where an exam is given. A VE, on the other hand, may have costs for transportation to the site of an exam and perhaps lodging expenses. Also, VE's will have postage expenses since they must forward the applications of successful applicants to the VEC. VE's may also have expenses for paper, pencils and supplies that are furnished to the applicants. We cannot anticipate every expense that a VEC or VE may incur. The statute provides that expenses may be reimbursed only if they are necessarily and prudently incurred by uncompensated volunteers. Proposed rule § 97.36 is intended to be flexible. It states that the VEC and the VE both may be reimbursed. However, they may determine how much of the reimbursement amount each will receive.

5. Present §§ 97.31 and 97.507 which relate to the VE and the VEC, respectively, provide that no compensation from any source may be accepted. We propose to amend those sections to allow for reimbursement of necessary and prudent expenses.

6. It would seem that in most cases the VE could most conveniently collect the reimbursement fee since the VE and the examinee directly interact. Candidates initially submit their applications directly to the VE's. However, in certain cases, a VEC may devise a program where the reimbursement is collected by it and then shared with the VE's to defray their out-of-pocket expenses. Varying conditions and practical necessities may affect who collects the money initially. Accordingly, we do propose to allow either the VE or the VEC to collect the fee. In the interest of flexibility, we will leave that to the VEC's and the VE's to determine.

7. The amount of reimbursement from each examinee, which may be less than the statutory $4 but may not exceed that amount, will be a reimbursement amount that is associated with *one* application. One application may result in a telegraphy exam and one or more written exam elements. All those tests will be covered under one reimbursement amount. However, once the application is acted upon by grant or by dismissal, the reimbursement amount is final. If an examinee fails an examination and later submits a new application, a new reimbursement amount may be collected.

8. As authorized by the legislation, we propose to allow the amount of reimbursement to be adjusted for inflation every January 1 as reflected in the Department of Labor Consumer Price Index. The new maximum would be stated annually in a public notice.

9. If fees are charged, both the VE and the VEC would be required to maintain records of out-of-pocket expenditures and certify annually to the Commission that all costs for which they obtained reimbursement were necessarily and prudently incurred. We would cancel the agreement that we have with a VEC if the VEC recovered more than out-of-pocket costs. Such cancellation is provided for in § 97.511 of our present rules. Section 97.33 provides that a VE will be subject to appropriate sanctions for recovery of any amount in excess of that permitted.

10. We believe that reimbursement for expenditures will make the program more attractive to volunteers and more effective. We will continue to administer some examinations in our field offices and at a few remote points in 1984 until such time as the volunteer program is in place. However, our resources for this work are very limited. We wish to implement the volunteer examination program as soon as possible for the good of the amateur community. Therefore, the comment period will be 30 days, with reply comments due 15 days thereafter. Requests to extend the time for filing comments or reply comments are discouraged and will not be routinely granted.

11. For purposes of this non-restricted notice and comment rule making proceeding, members of the public are advised the *ex parte* contact are permitted from the time the Commission adopts a Notice of Proposed Rule Making until the time a public notice is issued stating that a substantive disposition of the matter is to be considered at a forthcoming meeting or

---

[1] Section 4(f)(4) was amended by adding subparagraph (J) as follows:

"(J) With respect to the acceptance of voluntary uncompensated services for the preparation, processing or administration of examinations for amateur station operator licenses pursuant to subparagraph (A) or (B) of this paragraph, individuals, or organizations which provide or coordinate such authorized volunteer services may recover from examinees reimbursement for out-of-pocket costs. The total amount of allowable cost reimbursement per examinee shall not exceed $4, adjusted annually every January 1 for changes in the Department of Labor Consumer Price Index. Such individuals and organizations shall maintain records of out-of-pocket expenditures and shall certify annually to the Commission that all costs for which reimbursement was obtained were necessarily and prudently incurred."

[2] None of the proposed rules applies to the examination for the Novice Class license. Senator Goldwater, the sponsor of the legislation, stated, "[t]he legislation I am introducing today is not intended to have any effect upon the present novice program * * *". *Congressional Record-Senate*, S 15376; November 3, 1983.

until a Final Order disposing of the matter is adopted by the Commission, whichever is earlier. In general, an *ex parte* presentation is any written or oral communication (other than formal written comments/pleadings and formal oral arguments) between a person outside the Commission and a Commissioner or a member of the Commission's staff which addresses the merits of the proceeding. Any person who submits a written *ex parte* presentation must serve a copy of that presentation on the Commission's Secretary for inclusion in the public file. Any person who makes an oral *ex parte* presentation addressing matters not fully covered in any previously-filed written comments for the proceeding must prepare a written summary of the presentation; on the day of the oral presentation, that written summary must be served on the Commission's Secretary for inclusion in the public file, with a copy to the Commission official receiving the oral presentation. Each *ex parte* presentation must also state by docket number the proceeding to which it relates. See generally, Section 1.1231 of the Commission's Rules, 47 CFR 1.1231. A summary of the Commission's procedures governing *ex parte* contacts in informal rule makings is available from the Commission's Consumer Assistance Office, FCC, Washington, DC 20554, (202) 632-7000.

12. Authority for issuance of the Notice is contained in Sections 4(i) and 303(r) of the Communications Act of 1934, as amended, 47 U.S.C. 154(i) and 303(r). Pursuant to applicable procedures set forth in § 1.415, 47 CFR 1.415, of the Commission's Rules, interested persons may file comments on or before April 16, 1984 and reply comments on or before May 1, 1984. All relevant and timely comments will be considered by the Commission before final action is taken in this proceeding. In reaching its decision, the Commission may take into consideration information and ideas not contained in the comments, provided that such information or a writing indicating the nature and source of such information is placed in the public file, and provided that the fact of the Commission's reliance on such information is noted in the Report and Order.

13. In accordance with § 1.419 of the Commission's Rules, 47 CFR 1.419, formal participants must file an original and five copies of their comments and other materials. Participants who wish each Commissioner to have a personal copy of their comments should file an original and eleven copies. Members of the general public who wish to express their interest by participating informally may do so by submitting one copy. All comments are given the same consideration, regardless of the number of copies submitted. Each set of comments must state on its face the proceeding to which it relates (PR Docket Number) and should be submitted to: The Secretary, Federal Communications Commission, Washington, D.C. 20554. All documents will be available for public inspection during regular business hours in the Commission's Public Reference Room at its headquarters in Washington, D.C.

14. In accordance with Section 605 of the Regulatory Flexibility Act of 1980 (5 U.S.C. 605), the Commission certifies that these rules would not, if promulgated, have a significant economic impact on a substantial number of small entities, because these entities may not use the Amateur Radio Service for commercial radio communication (see 47 CFR 97.3 (b)) and because these rules would have no foreseeable impact on manufacturers of Amateur Radio Service equipment.

15. The request for agency action filed by the ARRL is granted to the extent that it requests rules to implement the legislation which permit reimbursements of volunteers who administer or coordinate Amateur Radio examinations and is denied insofar as it requests that such rules be adopted without notice and opportunity for public comment.

16. It is ordered, That the Secretary shall cause a copy of this Notice to be served upon the Chief Counsel for Advocacy of the Small Business Administration and that the Secretary shall also cause a copy of this Notice to be published in the Federal Register.

17. For information concerning this proceeding, contact Maurice J. DePont, Federal Communication Commission, Private Radio Bureau, Washington, D.C. 20554, (202) 632-4964.

Federal Communication Commission.
William J. Tricarico,
Secretary.

Appendix

PART 97—[AMENDED]

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended, as follows:

1. Section 97.31(c) is revised to read, as follows:

§ 97.31 Volunteer examiner requirements.

* * * * *

(c) Volunteer examiners may not be compensated for services. They may be reimbursed for out-of-pocket expenses, except for Novice class examinations (see § 97.36)

* * * * *

2. Section 97.33 is revised to read, as follows:

§ 97.33 Volunteer examiner conduct.

No volunteer examiner shall give or certify any examination by fraudulent means or for monetary or other consideration. Violation of this provision may result in the revocation of the amateur radio station license and the suspension of the amateur radio operator license of the volunteer examiner. This does not preclude a volunteer examiner from accepting reimbursement for out-of-pocket expenses under § 97.36. Recovery of any amount in excess of that permitted may result in the sanctions specified herein.

3. New section 97.36 is added, as follows:

§ 97.36 Reimbursement for expenses.

(a) Each volunteer-examiner coordinator and each volunteer examiner may be reimbursed by examinees for out-of-pocket expenses incurred in preparihg, processing or administering examinations for amateur station operator licenses above the Novice Class. The volunteer-examiner coordinator or the volunteer examiner must collect the reimbursement, if any, from the examinees. No reimbursement may be accepted for preparing, processing or administering Novice class examinations.

(b) The maximum amount of reimbursement is $4.00 and will be adjusted annually each January 1 for changes in the Department of Labor Consumer Price Index and announced by the Commission in a Public Notice. The amount of such reimbursement from any examinee for any examination or series of examinations related to a single application must not exceed the published maximum.

(c) A volunteer-examiner coordinator or volunteer examiner who accepts reimbursement must maintain records of the out-of-pocket expenses and reimbursements and must certify annually to the Commission's office in Gettysburg, PA 17325 that all expenses for which reimbursement was obtained were necessarily and prudently incurred.

4. Section 97.507(e) is revised to read, as follows:

§ 97.507 VEC qualifications.

* * * * *

(e) Agree not to accept any compensation from any source for its services as a VEC, except reimbursement for out-of-pocket expenses permitted by § 97.36; and

* * * * *

7882-103 Americana Circle
Glen Burnie MD 21061
(301)-766-7903

Need lots of help on how to FM the receive on the Drake TR-3 or TR-4, information and schematics, if possible.

Bob King WD8DLH
7900 Blackshear Drive
Huber Heights OH 45420

I am looking for information on (and to buy) a National NCU-27 100 kHz calibrator.

Joseph Karr KA5RKD
R 2, Box 291
Lakeview AR 72842

I need information on a VIP switch for an Icom 22S.

David E. Quagliana K2MTW
115 Los Robles Street
Williamsville NY 14221

I need the owner's and/or service manual for the Gladding 25 2-meter FM transceiver. I will buy or pay any expenses.

John H. Cox KA4ZII
1815 Wood Avenue
Burlington NC 27215

Wanted: Someone knowledgeable (and with the necessary test equipment) who has built the satellite receiver, "Lite Receiver IV," featured in *73* during March through June, 1982. I need my receiver aligned and evaluated and lack the proper test equipment and antenna to do the job. I would be willing to pay UPS charges both ways, but due to being totally disabled and on a fixed income, I cannot afford a lot in the way of other charges.

Thanks a lot.

John W. McGuire K7ZVP

Show Low AZ 85901

73 INTERNATIONAL

from page 76

QSO, and I gave Gerald 5/1 and he gave me 5/2. Gerald told me that he was using a simple ¼-wave antenna just above the roof. Later on, I shut down the station and went to bed. I took two tablets of painkiller to relieve my headache.

I was supposed to call my friend in Kota Kinabalu, 9M6MH, at about 1930 local time, but by then I was feeling too cold to be active again. There was no light in the shelter. We started a fire in the fireplace, but it died very fast because there was not enough wood. I finally slept at about 2000. I was told that the temperature at Panar Laban was about 6° C and it was about 2° C at the peak.

At about 0100 the next day, everybody woke up and had some canned instant noodles and warm coffee. We started to climb to the peak, 2,500 feet higher at 13,455 feet. It had been raining during the night. Since it was still dark, I used a torch light all the way.

We made another stopover at Panar Laban before going down to the National Park, and I had another QSO that morning from Panar Laban.

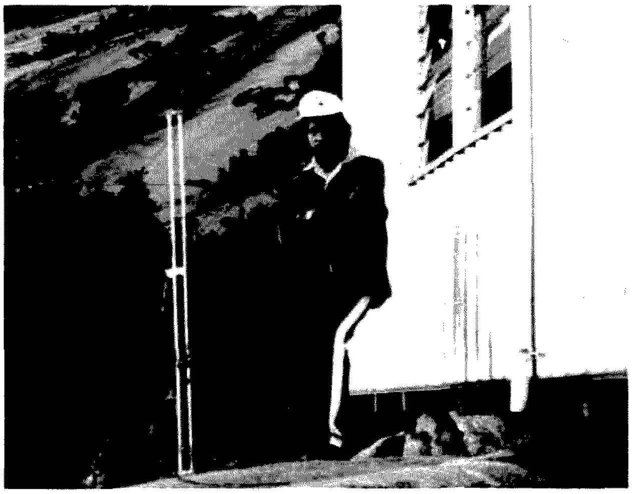
THE DUTCH PREFIX

In an earlier article, I told you about the different licenses in Holland: the A license for all bands and all modes, the B license for CW on some HF bands and all modes on 28 MHz and higher, the C license for all modes on 144 MHz and higher, and the D license for FM on two meters.

You can recognize a station's license class by its prefix (with some exceptions). In general, license class and prefix are as follows: A—PA0, PA2, PA3; B—PB0; C—PA0, PE0, PE1; D—PD0; Club stations—PI4; Repeaters—PI3.

On the way to Panar Laban. Left to right, Ismail, myself, Ahadiah, Teddy, and Sylvester.



At the Panar Laban shelter, about 1700 local time, with the Slim Jim at my right.

PI4NLB

This callsign is from the VERON club station in the region North-Limburg. It is on the air every Sunday morning from 1100 till 1200 UTC on 145.350, on FM, with regional news items. In the future, they will add some more frequencies.

THE DUTCH QSL BUREAU

The address of the Dutch QSL service is PO Box 330, 6800 AK Arnhem, The Netherlands. This Dutch QSL Bureau (DQB) sends all QSL cards from the members of the VERON and VRZA (the major societies in Holland) to every corner of the world. They collect the QSLs which are received at PO Box 330 and spread them among their members again. This gigantic service is free for hams and SWLs who are members of the earlier-named clubs. All the work is done by volunteers and their families in their spare time.

This year the DQB handled 1.5 million cards! I think that is a magic number!

THE HISTORY OF OM H. J. JESSE

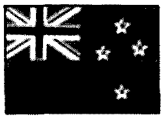
The name Jesse may say nothing to you, but let me tell you the story of this remarkable Dutchman. We go back to the year 1923, on the winter night of December 26. Mr. Jesse was the man who made the first contact with the States. He used then the call PC11.

Almost every part of his transmitter was homemade, because at that time shops where you could go for radio parts were not at hand. To assemble a radio transmitter, high technical knowledge was required.

Back in the twenties, radio amateurs like Mr. Jesse had no status. He couldn't get a license, and therefore his technical achievements were illegal. After his experiments, he was prosecuted by the authorities, and when his matter came to court, everyone was so thrilled by his achievements that, although they found him guilty, they did not lay any charges on him!

Last year in December, it had been sixty years since this pioneer had his contact with the States. For this occasion, Mr. Jesse was granted a full license; his callsign is now PA0C11.

I—and many hams with me—hope that Mr. Jesse makes use of this license, because who wouldn't like to have a QSO with such a remarkable man?



NEW ZEALAND

D. J. Chapmen ZL2VR
459 Kennedy Road
Napier
New Zealand

Last month I finished the section of the column on National Field Day activities in ZL with a mention of the usual weather conditions expected at that time of the year (February). How wrong I was!

National Field Day dawned to steady rain that had been falling from the early hours of Saturday morning. The same weather was predominant throughout the whole country. The rain continued for about 12 hours, easing just before the contest began at 1500 hours ZL time. So, as you can imagine, there were many very wet and miserable FD operators in action this year. A typical FD situation was as follows:

Arrive at the site about 10 am ZL time in fairly heavy and steady rain, to commence setting up the station. The first jobs are to set up the station's shelter and locate the portable generator. No doubt all outdoor types have attempted to put up tents in the wet; quite a formidable task, especially as the wind had just begun to get up a bit. However, after much difficulty, the shelter is erected and the two tents joined together with an access passage in case the rain continues all through the FD operating period. Meanwhile, a second team has set up the motor generator a reasonable distance from the station tents, placed a canvas shelter over the outfit to keep the rain off the motor and generator, and made several attempts to get the motor running.

Eventually the motor-generator is run-up and tested, much to the relief of the FD Controller, then shut down until later when the contest is about due to start. It is still raining, and now the wind has increased considerably. It *would* be like this, for now it is time to try to get the antennas up in the trees. While the other work had been progressing, a small team had been working to get the lines into the trees for the antenna supports. These vary from site to site, but everyone tries for the highest and best-located at their site.

Imagine trying to get lines up into large trees in these conditions. Yes, you have guessed—very frustrating, and there were many, many unprintable words spoken before the job was finished. There are many different methods used here: throwing pilot lines with a casting rod, using a kite and flying the lines into place, using a crossbow, and having a volunteer "idiot" climb the tree with the lines. Nevertheless, whatever method was used, all stations completed their antenna erections in atrocious conditions, with creditable results.

At one station I have heard of, the wind was blowing so strongly that branches from the 100-foot poplars were breaking off and adding to the hazards of the wind and rain. In fact, so I'm told, one fairly hefty branch hit the FD Controller's car parked nearby and caused panel-shop repairs amounting to over $300; can you imagine what his XYL said when he got home from Field Day? Just as well the branch didn't hit any of the FD team or there would have been graver problems than one damaged car.

Once the antennas were well on the way to being erected, then a small team began organizing the station setups for the 80- and 40-meter operating positions, one in each tent. When all the cabling and antenna connections were nearly completed, the generator was again fired up, the voltage adjusted to the load, and some test calls put out to other FD stations in a similarly wet state to ours.

After all seems well, the FD Controller allows the crew to have lunch and to try to dry off a bit. The wise ones in the team have brought a change of clothes and towels to dry off with. And while the FD team is having its first break since 10 am, the weather begins to clear. By the time the first FD calls were put out, at 1500 hours, the rain had stopped and the wind decreased a bit to make conditions a little bit more pleasant than they were a few hours earlier.

For the record, this year's ZL National Field Day attracted about 50 of the 79 eligible Branches into the field, with some of the larger Branches putting in more than one team. The number of Branches operating this year was less than last year, but than, 1983 was WCY year, and no doubt there was a bit of an extra effort and emphasis placed on last year's event for that reason. Nevertheless, it was still a good turnout, considering the atrocious condi-

tions during the setting-up period. As far as I can ascertain, only one team abandoned efforts because of the weather conditions, and this was a two-man team, so it was not too surprising.

1984 saw the first time that a full YL team operated. The "girls" were based at Inglewood in a mobile motor caravan, but even so had to contend with the wind and rain when putting up their antennas, etc. Another FD group with a difference was the station set up in a local school ground by an Auckland Branch as an amateur-radio PR exercise. The tents were erected in the middle of the school sports field, and there was suitable publicity in the local papers to encourage interested locals to visit and find out a little of what amateur radio is all about. I haven't heard how the response was, but while weather conditions on the Saturday were not good for the PR exercise, Sunday's weather was much improved.

There are always many hard luck stories from Field Day and no doubt many of these will continue to come out over the next few months, but the one I heard about was a real honey. The FD Controller had been chastising his team, urging them to try harder and make more contacts, etc., when it was time to check the motor generator for gas, etc. By now darkness had set in, so the job had to be done with a flashlight (very difficult holding a flashlight and filling the gas tank simultaneously) or by plugging in the service lamp. Well, the FD "boss" decided to plug in the service lamp. It had not been checked, and yes, you guessed right, it had a fault caused by the wet conditions; when plugged in, it upset the generator and put the station off the air. Mad panic! Get the standby generator! Attempts to start the standby failed! Then somebody decided to check the standby generator for gas. The tank was empty!

You can imagine the red face of the FD Controller. . .he has never lived that episode down and won't be allowed to forget it for many years to come. The "off-air" period was about 15 minutes at a prime time, so it was a bit embarrassing to the "boss man." Eventually, the main generator was restarted and the standby motor generator not required, but it was left gassed up just in case.

Front contenders for the FD contest honors will come from the following Branch teams: Manukau Branch ZL1QB, near Auckland; Auckland VHF Group ZL1BQ; Napier Branch ZL2ABJ; Auckland Branch ZL1AA; and Franklin Branch ZL1SA, near Pukekohe, south of Auckland.

BITS 'N' PIECES

I am including with this column a chart showing the ZL band plans, which should be of interest to amateurs worldwide. Our regulatory body, the NZ Post Office, in 1983 delegated the responsibility for planning within the amateur bands to NZART and amateurs themselves, and NZART accepted the task. The band plans are developed by the Frequency Management Working Group (FMWG) of NZART, based on IARU recommendations and local requirements, and all ZL amateurs are required to observe the published band plans "to assist others to follow their interests with a minimum impact on amateurs, and to assist amateurs to follow their interests with a minimum of impact on others."

In just over a year from now, ZL amateurs will host the IARU Region III Association Conference in Auckland from November 13-18, 1985, during IARU's Diamond Jubilee year. This will be the first time New Zealand has organized an International conference, and a fitting prelude to the NZART 60th Jubilee to be celebrated in 1986.

Silent keys of recent weeks include Bob Robertson ZL4AC, originally 4AC of Dunedin, a 60-year operator, who passed away on Christmas Eve, 1983. Also, Clem Smith ZL2DM of Gisborne, and Johnny Palmer ZL1KV of Mt. Albert, Auckland.

NEW ZEALAND BAND PLANS

These plans help you comply with the official Frequency Allocation List: "The class of emission from an amateur station shall be selected in the light of the total available bandwidth for all users and shall be in accordance with current operating practice." These plans represent current operating practice. See *Callbook* for designated frequencies and detailed band plans.

All amateurs are reminded of (1) The ITU Radio Regulations (Edition of 1982), including: 307. The bandwidths of emission shall also be such as to ensure the most efficient utilization of the spectrum; in general this requires that bandwidths be kept at the lowest value which the state of the technique and the nature of the service permit. 1804. All stations shall radiate only as much power as is necessary to ensure a satisfactory service.

(2) The New Zealand Radio Regulations 1970, including: 40. (Not to cause harmful interference to other stations). 45. (No monopoly of allocated frequencies). 147. (Permitted power limit).

(3) NZART Current Policy, Section 12A, Band Plans, (*Break-In*, page 2, October, 1983): d. All radio amateurs are requested to observe the published New Zealand band plans which are to assist others to follow their interests with minimum impact on you, and to assist you to follow your interests with minimum impact on others.

Band (MHz)	Emission (See notes)
1.8-1.95	6
3.5-3.55	N
3.55-3.9	6
7.0-7.03	N
7.03-7.3	6
10.1-10.5	N
14.0-14.1	N
14.1-14.35	6
18.068-18.11*	N
18.11-18.168*	6
21.0-21.1	N
21.1-21.45	6
24.89-24.93*	N
24.93-24.99*	6
27.12 ± 0.163	T
28.0-28.1	N
28.1-29.5	6,B,S
29.5-29.7	10
50.0-50.15	6
Amateur bands 51 to 440 MHz	30,B,R,S
Amateur bands 440 MHz to 1.3 GHz	7,B,R,S
All amateur bands above 2.3 GHz	W,B,R,S

*When available.

N = Narrow-band modes: i.e., CW and RTTY. RTTY operating is normally at the high-frequency end of the segment. *Callbook*-listed selcal (RTTY selective calling) frequencies should be avoided by stations using other modes. SSB phone may be used for Morse practice texts by stations in 3.53-3.55-MHz segment.

6 = All modes except MCW and AFSK, to a maximum bandwidth of 6 kHz.

10 = All modes except MCW and AFSK to a maximum bandwidth of 10 kHz.

30 = All modes to a maximum bandwidth of 30 kHz.

7 = All modes to a maximum bandwidth of 7 MHz.

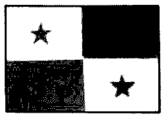
W = Wideband modes.

B = Beacons: Transmitting on *Callbook*-listed beacon frequencies should be avoided.

R = Repeaters: Transmitting on *Callbook*-listed repeater frequencies should be avoided for direct contacts in their service areas.

S = Satellites in current use: Terrestrial contacts are not recommended in the segments 29.3-29.5, 145.8-146.0, 435-438, 1260-1270 MHz and on higher satellite-used frequencies.

T = Telecontrol and telemetry only.



PANAMA

Robert H. Emerick
W4YTM/HP1XRO
President, Canal Zone Amateur Radio Association
PSC Box 2029
APO Miami FL 34002

It had been 15 years since Ms. Caballero, a resident of Marshalltown, Iowa, had left the Republic of Panama as a young child. In the interim, she had lost contact with her father, still in Panama. Her ardent desire to re-establish contact with her father and to rediscover her Panamanian roots inspired Marshalltown, Iowa, amateur-radio operator Fred Meyer NØCFJ to try to help her.

One of the calls he made just happened to be picked up by James "Red" O'Donnell HP1XJL, Panama Canal Commission supervisory power dispatcher, in the home of Occupational Health Division Chief, Dr. Ernst Kredel HP1XEK. Like Fred Meyer, Jim O'Donnell could not help but get into the act.

Armed with only a name and the information that Ms. Caballero's father had been both a barber and a firefighter, Jim visited Panama's Balboa Fire Station to ask the firemen (bomberos) there if they knew of such a man. By chance, one had heard of a Sergeant Alvarado who worked at Panama's international airport. Jim was then able to locate Mr. Alvarado and establish that he was Ms. Caballero's father.

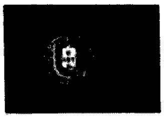
A phone patch was arranged through HP1XEK to allow father and daughter to speak, although the conversation was somewhat impeded by the fact that he spoke no English and she no Spanish. The hams were thrown into the conversation as translators.

Before long, Mr. Meyer and the fire department in Iowa were raising money to send Ms. Caballero to Panama. In Panama, a number of firefighters and ham operators were making arrangements for Ms. Caballero's arrival. These included Commission civil engineer Tomas Duque, treaty affairs specialist Robert Emerick HP1XRO, Graphic Branch equipment specialist Bob Rodgers HP1XRQ, Commission Fire Chief Jaye Dietz, and Republic of Panama bombero Capt. Christian Arnheiter. Overwhelmed by all their assistance, Ms. Caballero said, "This is simply fantastic. I had no idea so many people cared!"

Ms. Caballero's 10-day visit was characterized by a whirlwind of activities. She met with representatives from, and visited points of interest in, both Panama and the Canal area, including the Miraflores Locks and other Commission facilities. But the highlight of the trip was, of course, getting reacquainted with her father. Once again, ham radio brought

From left to right, James O'Donnell KB4HMO/HP1XJL, Robert Emerick W4YTM/HP1XRO, Dr. Ernst Kredel WA7ARU/HP1XEK, Ms. Nora Caballero, her father, Anival Alvarado, and Bob Rodgers HP1XRQ.

some happiness to people at different locations in the world.



PORTUGAL

Luiz Miguel de Souse CT4UE
PO Box 32
S. Joao do Estoril
2765 Portugal

Let me introduce you to two very interesting Portuguese awards, sponsored by REP:

(1) *DMP-WPW—Worked Portuguese World.* QSO or SWL ten different stations in ten Portuguese possessions, using any mode or band after July 29, 1947. Countries are: Portugal, Azores Islands, Madeira Island, ex-Portuguese India (not required), Cape Vert Island,* St. Tome and Principe Islands,* Angola,* Mozambique,* Portuguese Timor,* and Macau. (An asterisk means contacts made during the Portuguese administration of that country.)

(2) *DPCI—Worked Portuguese Provinces.* QSO or SWL 50 different CT stations, with 26 contacts in different provinces and islands, using any mode or band after January, 1952. Minimum QSOs with each province: Traz os Montes e Alto Douro—1, Minho—1, Douro Litoral—5, Beira Litoral—1, Beira Baixa—1, Beira Alta—1, Estremadura—10, Ribatejo—1, Alto Alentejo—1, Baixo Alentejo—1, Algarve—1, Acores—1, Madeira—1.

For these two awards, submit QSLs or list certified by an IARU-affiliated radio society and send to REP-REDE Dos Emissores Portugueses, Rua D. Pedro V, 7/4, Lisbon, Portugal, and do not forget to include 3 or 4 IRCs to cover the expenses.

As said before, the country is covered by some repeaters for VHF and UHF. A repeater's frequencies are established according to the IARU Region I band plan for VHF. So these are the repeaters, followed by their locations.

R9—CT6SE (Serra da Estrela)
R1—CT9LO (Lousa)
R2—CTØFO (Fola)
R2—CT9LE (Leiria)
R3—CTØFF (Figueira da Foz)
R3—CTØMAD (Pico Silva—Madeira)
R4—CT9MS (Monsanto—Lisbon)
R4—CTØMA (Serra do Marao)
R5—CTØSM (Cerro S. Miguel)
R5—CTØSA (Castelo Branco)
R6—CT9MO (Montejunto)
R7—CT9AR (Arrabida)
R7—CTØSL (St. Luzia—Viana do Castelo)
R8—CTØSI (Sintra)
R9—CTØES (Estremoz)
R9—CTØVA (Valongo)

UHF

RUØ—Monsanto
RU1—Serra da Estrela

In Lisbon with a hand-held, try R4, R7, R8, and RUØ.

Operating Advice For Licensed Radio Amateurs, the new publication issued by the IARU, is very helpful for new hams in order to guide them in a good operation in the DX frequencies.

According to a proposal presented by GRA (Grupo de Radioamadores do Algarve), the local administration deliberated that those interested could use other prefixes during WCY/83 instead of the well-known CT that we use daily. So, during that period of time, a lot of Portuguese hams activated CO, CR, CS, and CU.

Some of these prefixes have been in QRT since the independence of the ex-Portuguese colonies in Africa, if we all remember the old good days back in 1974/5 in Angola CR6 (CQ6, XX6), Mozambique CR7, Portuguese Guinea CR3, S. Tome and Principe Island CR5, and Cape Vert Island CR4.

It is real nice when we have other prefixes in contests.

I still remember when I went on the air using CR6UE, CQ6UE, and XX6UE in that time. We had a lot of fun. But this isn't all. We just received information from Macau CR9 saying that they would be using XX9 in the very near future.

It is a good chance to increase our WPX list.

DXPEDITION TO BERLENGA ISLAND

Four REP members, CT4UW, CT4NH, CT1AFN, and CT1CEX, were operative last March from Berlenga Island, 6 miles off the Portuguese coast at the city of Peniche, working a very special (1st World) callsign, CTØBI.

Berlenga is valid for the IOTA Award (Islands on the Air), having IOTA's number EU-40, and obviously good for WPX hunters.

The operation took place from the existing lighthouse, under Portuguese administration. Transportation and other facilities were graciously given by the Portuguese Navy. QSL cards via home calls (*Callbook* address). More about this later.

CRC—CLUBE DE RADIOAMADORES DE CASCAIS

This is a result of the efforts undertaken by a group of hams living in the municipality of Cascais. This ancient village, founded in 1400, is situated 12 miles west of Lisbon and 6 miles from Roca's Cape, where the European continent just begins.

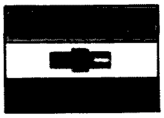
The area is surrounded by beaches, nice hotels, golf courses, souvenir shops, and, of course, the typical restaurants in which you must try the real Portuguese cuisine.

CRC is sponsoring two interesting awards for licensed amateurs as well as SWLs worldwide:

1) *100 CT Award.* For this one, contacts must be made after February 13, 1984, with 100 or more different CT stations, with at least 3 CT3 (Madeira) and CT2 (Azores) stations.

2) *CCA—Cascais County Award.* Contacts after February 13, 1984, with the six administrative divisions in Cascais County: Alcabideche, Carcavelos, Cascais, Estoril, Parede, and S. Domingos de Rana.

These two awards are issued for any band, CW or phone, as well as mixed- and single-band accomplishments. To apply, a list of contacts must be verified by two amateurs or local radio-club officials. Send a list plus 12 IRCs or US$5.00 to CRC Award Manager, PO Box 209, 2752 Cascais, Portugal.



REPUBLIC OF SOUTH AFRICA

Suid-Afrikaanse Radioliga
Tak Durban Branch
Posbus 1058 PO Box
Durban 4000
Republic of South Africa

On May 31, 1984, to celebrate Republic Day in South Africa, the Durban Branch of the SARL will operate special callsign ZS5RSA. The operation will cover 3.5–28 MHz, CW and SSB, as far as band conditions permit. This is the fifth consecutive year that this activity has taken place and it has proved very popular. A special QSL card is normally issued for contacts with this station.

de Bruce P. Dunn ZS5XT

TRINIDAD AND TOBAGO

John L. Webster 9Y4JW
c/o Department of Soil Science
University of the West Indies
St. Augustine
Trinidad
West Indies

The biggest event in the WCY 1983 TTARS calendar occurred during the last week of October. This event was a national exhibition on communications in which the TTARS participated. It was a major contribution by the government of Trinidad and Tobago to World Communications Year.

The exhibition was officially opened on Sunday, October 23, by the President of the Republic and was open to members of the public daily between the hours of 10:00 am and 9:00 pm, until Saturday, October 29th. There were exhibitors from all sections of the commercial communications field, and many computers were in evidence.

The TTARS prepared an impressive exhibit in its attempt to educate the public about amateur radio. Brochures describing our hobby were prepared and distributed to all visitors to our booth. We attempted whenever possible to have three stations operating simultaneously, one on VHF simplex or the local repeater and the other two on the HF bands. Whenever we had two HF stations on simultaneously, we tried to utilize two different modes in order to demonstrate the versatility of this exciting hobby. The modes we were able to demonstrate were SSB, CW, and RTTY. Unfortunately, for much of the exhibition the propagation was poor, but about 1000 QSOs were logged using the special callsign 9Y4WCY. (Anyone wishing to confirm a QSL with 9Y4WCY should QSL to 9Y4TT.)

The antenna systems in use at 9Y4WCY consisted of two three-element triband yagis for 10, 15, and 20, a longwire for 80, and a KLM four-element yagi for 40. The latter presented quite a challenge both in finding a suitable site on which to position it and also in the actual erection of the beam. It was eventually placed, with the aid of a mobile crane, on a tripod on the top of the elevator shaft of the building housing the exhibition, at about 25 meters above ground level.

We also had all of the components of a satellite station on site with the expectation that we would be able to work OSCAR 10. Unfortunately, this was not to be, as problems developed with the equipment. When these problems were eventually sorted out, it proved impossible to hear the satellite due to the extremely high level of VHF/UHF interference being generated by the large number of computers and other communications equipment in operation on the site.

This was a great disappointment to us, but we were still able to explain amateur satellite communications to our visitors through the use of posters, brochures, and with the aid of the AMSAT AMS-81 tracking program running on the low-cost Timex TS-1000 computer.

Other exhibits included a comprehensive publications display, vintage equipment, a display showing the progression of technology from tubes to integrated circuits, an assortment of maps and posters, home-brewed equipment, and a selection of QSL cards and amateur-radio awards.

The WCY exhibition was the first real exposure to the public that amateur radio here has received. It was quite a success for the TTARS as several thousand persons visited our booth and 40 new associate members have joined the Society as a direct result of the exhibition. Most of them are now attending our current training program.

Several companies and individuals provided much of the material used to help make the show the success it was. The TTARS would like to publicly thank the following for their contributions: ARRL, RSGB, JARL, AMSAT, *CQ*, *73*, *Radio Amateur Callbook, Inc.*, Varian EIMAC, Kantronics, RCIS, Inc., Computer Applications, RCA, KØRZ and KØCY of AMSAT Software Exchange, Bob Jackson AG5X, and Jack Gutzeit W2LZX.

1983 was the year that the personal computer age really got off the ground here in Trinidad and Tobago. In the latter half of the year, many of the hams got into the act as well. As a result, the need arose for some guidance in programming in Basic for the newcomers from some of the more experienced computer hackers. This took the form of half-hour lecture/discussion sessions on the air during the weekly 9Y net, conducted by Russ 9Y4RB and Lloyd 9Y4DK. This net meets every Sunday at 1300Z on 7.159 MHz.

The final notable event in the 9Y calendar occurred with the launch of STS-9, *Columbia*, with Dr. Owen Garriott W5LFL on board. The possibility of working W5LFL stirred up considerable interest here. On Friday, December 2nd, between 2322Z and 2330Z (Orbit 70D—the only one on which Dr. Garriott was supposed to be operating that really favored Trinidad), there were at least a dozen 9Y stations keeping a racket on W5LFL's range of listening frequencies . . . but it was all to no avail. Not a peep was heard from *Columbia* and there were a lot of disappointed hams here in Trinidad. We are hoping for better luck next time!

HAM HELP

Am interested in modifications for a Standard C-118 2m HT, especially how to reduce the output power.

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego, 827-5732 (Reno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.

San Jose CA

Bay area's newest amateur radio store. New & used amateur radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Azden, AEA, Kantronics, Santec. Full line of accessories. No sales tax in Delaware. One mile off I-95. Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.

Boise ID

Rocky Mountain area's newest ham dealer. Call RJM first for AEA, Azden, KDK, Ten-Tec, Butternut, Cushcraft, and more! RJM Electronics, 4204 Overland, Boise ID 83705. 343-4018.

Preston ID

Ross WB7BYZ has the largest stock of amateur gear in the Intermountain West and the best prices. Call me for all your ham needs. Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.

Littleton MA

The reliable ham store serving NE. Full line of ICOM & Kenwood. Yaesu HTs, Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delta protectors, ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. TEL—COM Electronic Communications, 675 Great Rd. (Rt. 119), Littleton MA 01460, 486-3400/3040.

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, DenTron and many more. Open Monday through Saturday, 0830 to 1730. WB8VGR, WB8UXO, WD8OKN, and W8RP behind the counter. Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor MI 48104, 668-8696.

Livonia MI

Complete photovoltaic systems. Amateur radio, repeater, satellite, and computer applications! Call Paul WD8AHO. Encon Photovoltaics, 27600 Schoolcraft Road, Livonia MI 48150, 523-1850.

Hudson NH

Look!—hams, SWLs, and experimenters: parts, books, gear, antennas, towers. Call for quotes. Polcari's ELECTRONICS CENTER, 61 Lowell Road (Route 3A), Hudson NH 03051, 883-5005.

Albany, New York UPSTATE NEW YORK

Kenwood, ICOM, Ten-Tec, Belden, Cushcraft, Larsen, Hustler, ARRL, Hy-Gain, B&W, MFJ, Mirage. New and used equipment. Serving the amateur community since 1942. Adirondack Electronics, Inc., 1991 Central Avenue, Albany NY 12205, 456-0203 (one mile west of Northway exit 2W).

Columbus OH

The biggest and best ham store in the Midwest featuring Kenwood and other quality products with working displays. We sell only the best. Authorized Kenwood service. Universal Amateur Radio, Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.

Dallas TX

IBM PC/XT kits, supplies, expansion products; video restorer kits for pay TV, CATV, satellite hobbyists' electronic project kits/app-notes. More than 9000 parts in stock: semiconductors, ICs, discretes, video accessories, tools, audio, automotive, cabinets, computer peripherals. Please write for your free 60-page catalog: Sabet Electronics, 13650 Floyd Rd., Ste. 104, Dallas TX 75243; 783-4950 (formerly I.E.).

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the September '84 issue must be in our hands by July 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.

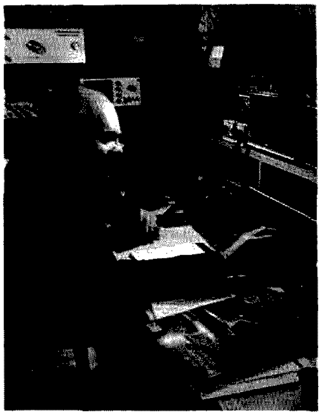
Dayton—10

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



THE HAMVENTION

Dayton was as big as ever—or bigger. Hara Arena was pretty full on Friday, packed on Saturday, and pretty full on Sunday with hams not just from the midwest, but from all over the world. There was even a ZS contingent from South Africa wondering when I was going to get back down to visit them again.

A handful of old-timers groused about my 35-wpm petition, but 99% got the point and enjoyed it. Some *73* readers were suckered in by media reports and did Archie Bunkers. (See my talk.)

A few years ago, I got to talking on Friday—mostly because the meeting rooms they had available then were so noisy on Saturday as to be almost impossible. They've built some new (quiet) meeting rooms, so I hope to be invited to do a Saturday talk next year.

Yes, I enjoy the acclaim I get—It helps a lot when I get to feeling discouraged. I get more pleasure than I can describe when I meet people at shows who tell me that my talks or editorials inspired them to change.

If you haven't been making the yearly pilgrimage to Dayton, maybe 1985 is the year to get off your duff. These DARA fanatics have their Hamvention worked out in every detail (and I emphasize the word *work*). Zillions of prizes, all reported on computer monitors. Somehow, they manage to guide the cars bringing over 20,000 hams into neighboring fields. They even have the incredible flea market well organized. It goes on for acres—the biggest one I've ever seen. I spent a couple hours walking around it this year and didn't even cover half of it. You wouldn't believe the amount of stuff there! You can find any model rig or receiver ever made, any test equipment, any radio part, any tube, transistor, IC, wire of any kind, coax, connectors, and so on. It's all there at prices that are hard to pass up.

If you want weather stations, laboratory clocks, muffin fans, relay racks, hi-fi, lo-fi, an old Emerson radio, Teletype®, relays, telephones, slow-scan, RTTY—you name it and it's there on hundreds of tables. There were even some EE8A WWII surplus telephones and some Gonset Communicators. I thought those had reached their final resting ground long ago.

The temperature went from the 40s the day before up into the 80s for the hamfest, forcing me to grovel at the Kenwood booth for a hat to keep what's left of my brains from frying while I was doing the flea market.

At the *73* booth, I shook a lot of hands, got my ego properly rebuilt, and met an enormous number of old friends. Larry Horne N2NY was there. He used to work for me almost 30 years ago. He's worked out some really fast Morse-code teaching techniques and has been reputed to get newcomers started at 50 wpm and copying in one weekend. Why spend months starting at 5 wpm and gradually relearning the code all the way up, driving yourself and your family crazy, when you can just as easily start out at 50 wpm? I dunno if these people can copy 5 wpm or not...probably not. Probably not even 13 per, but at 50...no strain.

If you're going to make it to Dayton next year, be sure to drop me a QSL card and let me know what subjects you'd like me to talk about. For that matter, if there's something you think I should cover in an editorial, hey, this is a two-way street.

Some ham dropped by the booth and beefed to Jim Gray W1XU that Wayne has his editorial and that the readers have no way to be heard. Jim asked him if he'd written a letter to the editor. Grumble, no. So write one, said Jim. A couple minutes later, the same chap started loudly with the same theme, more interested in generating a fuss than in accuracy. Letters with anything worthy of being printed will be printed. General beefs or emotional harangues probably won't make it—unless our Executive or Managing Editor wants to expose the vacuity of thought which characterizes some letters.

On the whole, I'm awfully proud of *73* readers. You are, with very few exceptions, intelligent and perceptive people. I don't write for 12-year-olds. I write for intelligent hams and most readers respect this. The 12-year-olds, of all ages, can have problems understanding me.

THE DAYTON TALK

[At 2:00 pm on April 27, Hara's Room 2 hosted W2NSD's yearly report on where amateur radio is today and where it could be tomorrow. And what to do about it. We hope you enjoy this transcript of some of his remarks. —JCB.]

Good afternoon. I'm Wayne Green W2NSD. And I understand that you read my editorials but don't agree with them 100 percent. [Loud guffaws. —Ed.]

So on that basis...had a number of questions asked me since I've been here. And I'll try to address most of those, if I can. If I forget some of them, make a note and ask me later, and I'll try to cover whatever I've forgotten about. But, in general, I cheat on my talks. I don't plan much ahead. And I figure either I'll think of what I was supposed to talk about or you'll remind me.

Now, since my talk last year, we've had a few minor changes in my organization. And those of you who read the magazine are aware that basically I sold all of the Wayne Green, Incorporated, magazines to another company, IDG, International Data Group, who publishes *Computerworld* and about 50 magazines in 18 countries. It makes it very handy for travel—there is always a company office there.

I got a good deal out of it, as you may have read. And people keep wanting to know, "What are you going to do with the 60 mill?" [Guffaws.]

Well, I'll tell you. I'm going to try to put it to the best use I can and do my very best to make an awful lot of people very wealthy. It's an old story that you can't take it with you. And indeed, the agreement I made was that whatever's left over when I leave goes back to the company.

Now, all of the reasons that I made that arrangement—one of the reasons that I made the deal with IDG—is that they were aiming in the same direction that I was. It was my intention to take Wayne Green, Incorporated, and eventually have the employees own it. IDG is doing the same thing. And indeed they have turned a substantial percentage of the corporation over to the employees' fund already. And the schedule eventually will be 100 percent of it. ["Superham" Don Wallace W6AM enters room and sits down in front row.]

With the bo-nanza, I have formed a new company called Wayne Green Enterprises. And I have a number of projects in the works with that. And I'll tell you about some of those because they have a lot to do with my background in amateur radio. (Hi, Don, good to see you. Delighted that you could come.) And I think that I have some plans that may eventually help amateur radio a lot.

We're starting out, essentially, with a new publishing organization. And in order to get the people to do this, I'm starting a

publishing school. And we have about 10 magazines lined up to get started with the people that we train in this school. And, of course, the people who do well in school we'll put on the new publications. The people who do poorly, we'll sell to our competitors. [Chuckles.]

The new magazine, the first one, will be *Digital Audio*. And how many of you are not familiar with digital audio in the compact disc? Are any of you out of communication with the world? [Chuckles.] OK. Well, perhaps you remember the 78-rpm record. And then there came along a newfangled contraption called a long-playing record which within a few years put the 78-rpm record out of business.

Well, there is a new technology called digital audio which is going to put the LP out of business in a very few years. And the new record is the compact disc which is about yea big. And it is written on and read by laser. And it is so phenomenally better than LP records that you have to hear it but once to be addicted to this new sound. For the first time, when you listen to hi-fi, you can hear the sound of silence. And for you technical people, you have the potential with this new recording medium of a 95-decibel range of sound (where on an ordinary record about the best that they can do is around 60 dB). So it's thousands of times better. Well, we're going to try to help this industry, this brand new industry, to grow with a magazine.

The second magazine will be in the telecommunications field and this will be for businessmen so that they will be able to cope with these new telephones and new types of communications that are on the market. Right now, I know of no magazine out there for businessmen to tell them what these things do.

We have two or three computer magazines in the works. And one would think that with 300 magazines on the market that there would be enough, but there still is a need for a few more that other people have not yet perceived. And we will be proceeding with that.

Now, perhaps even more important, once we have gotten things running fairly smoothly with these relatively easy magazines, we have two huge ones in the works. And when I say huge, I mean circulation on the order of 10 to 20 million. What I intend to do is take the 60 million [dollars] and within four years build that up to one billion. And I think we're going to be able to do it. And I believe that every person that works for us is going to be, at the minimum, a millionaire. My calculations are that within four years they should be worth approximately 1.6 million each. Because we're putting aside part of the stock and the people who work for us have a share in the company.

The big magazine—and the one that is going to be the most important to amateur radio—will have to do with teenagers. And basically, we want to start a magazine which is an instruction book for growing up. And you can bet that it is going to be very heavily laced with high tech. It'll encourage kids to be interested in amateur-radio communications, to be interested in computers.

I think all of you are well aware of what's happened in computers. How many of you here have Model 100s already? One, two, three, four, five, not bad, six, seven, right. A year from now, I suspect there will be at least ten times that many in the audience that have briefcase portable computers. But these computers are just part of it. It's what these are going to force to happen that is important. And that is the key for anyone who would really like to make money, because these small computers are going to require communications.

Right now, you can plug this [holds up Model 100] into the telephone and you can communicate through hundreds, any of hundreds, of bulletin boards, communications services, and so forth. The next step—and it's something that we could do with amateur radio *right now*, if we wanted, with our current technology—any one of you could probably do this if you'd sit down and do it. And that is put a small relay transmitter in here, probably 149 Megahertz, and make it so if you use this within the room with a small room repeater, it would pick up the information from that so you don't have to plug it in anymore. And you could hook that onto the telephone. That's the first step.

The next step is to have an area repeater so that the room repeater goes to your area repeater. Any of your regular repeaters that you have today could do this. Have the area repeater, say, every five minutes, or every three minutes, or every minute, send a pulse out with a coding for your particular computer and it says essentially, "Are you turned on? Do you have any traffic?" And your computer, if you have it turned on, will say, "Yes, I'm turned on, I have no traffic," every so often. It will take a few milliseconds to do it.

Once you *have* written the message to someone *anywhere in the world* and you say "Go," the next time you are polled by that local repeater through your room repeater, it will say, "Yes, I have traffic." And it will dump it *with error-correcting* at *25,000 words a minute.*

And that will be stored in your local repeater, which will then look up to see where-in-the-devil this thing is going and route it either to another repeater or to a local recipient or perhaps by a satellite link to somebody down in Ceylon [Sri Lanka] who was sitting on the beach with another system. Or to his home repeater waiting for when he comes home and turns on his unit and it finally says, "Yes, I'm here, is there any traffic?"

We can do that with the technology we have today. Nobody has to invent a *thing*. We just have to *do* it.

If you do it, you know as well as I do that there is no power on Earth going to stop that from selling. It is a service that is needed desperately. And some bright person somewhere is going to do that and going to become incredibly wealthy and you're going to say, "Gee whiz, look at that, how did he do that, wasn't he lucky?" I find that the harder I work, the luckier I get.

So these things are there. We are going to need communications in 10 years that are on the order of a thousand times—maybe ten thousand times—what we have today. And that means that we are going to need ten thousand times as many engineers and technicians as we have today.

Now, I'm sure that most of you are aware that the growth of amateur radio last year was two and a half percent. And that this year we're looking for a net loss. Unless something changes radically. I'm sure you're *also* aware that the growth of amateur radio in Japan last year was 25 percent and has averaged, over the last 20 years, over 300 percent a year. It slowed down a little bit in the last few years. We have averaged for the last 20 years a growth of 2 percent. Average. Two point zero percent in the United States.

I wrote in *73*—a couple of years ago—an editorial, and I said I bet you it isn't going to be long before our military are sending electronic development contracts to Japan. And I got the biggest bunch of hee-haws from the readers. And they said, "Boy, are you crazy." Big headlines about four months ago: The military tried to get electronic contracts with Japan for military equipment development and they turned us down.

I'd like to do something about that. I'd like to reach teenagers and interest them in amateur radio. In the United States, we

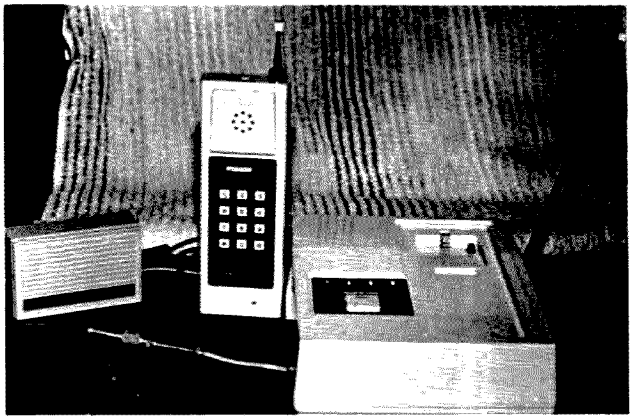
Secrets of Cordless Phones

Is privacy sacred and range not?
Maybe some hands-on research can help you decide.

I purchased a wireless telephone some time ago. Being curious about electronic gadgets, I did some hands-on research by examining the electronic innards and came up with a few mods and suggestions to make it even more useful. Wireless phones employ full-duplex operation and consist of two parts. The hand-held unit transmits on 49 MHz and is crystal-controlled. The base unit transmits on about 1700 kHz but uses an LC circuit. Its frequency can be adjusted by a tuned slug. Both operate in the FM mode. There are several ways to increase the phone's range and still preserve your privacy and avoid interference.

First of all, if you are considering the purchase of a wireless phone and you already own a programmable police scanner, enter in the following frequencies: 49.830, 49.845, 49.860, 49.875, and 49.890 MHz. Scan these five channels for a few days to get an idea which frequencies are most populated in your neighborhood. Using a Bearcat 250 with an outdoor antenna, I was able to get clear reception for over one-half mile. You may hear a juicy thing or two because people just don't realize others can listen in. For this reason, avoid initiating credit-card calls over a wireless phone. Remember, you'll only hear one side of the conversation—the hand-held unit's side. The other side of the phone conversation is carried on 1695, 1725, or 1755 kHz, although there are a few newer designs which duplex both sides of the conversation in the 49-MHz band.



Amplifier speaker, hand-held unit, and base unit.

The 49-MHz frequencies are designated as channel numbers or letters. For example, 49.830 is channel 1 or A, 49.845 is channel 2 or B, and so on. The wireless phones are usually marked on the outside of the box they are packed in which channel they operate on. In my neck of the woods 49.845 MHz seemed to have the least amount of traffic so I purchased a unit marked "channel 2." It's a good idea to avoid channel 3 or C (49.860). All the new unlicensed kid handie-talkies operate on this frequency these days, and even though they are AM, you will still receive some interference. If you don't have a scanner to check out the neighborhood frequency usage, you'll have to take pot luck. Just avoid channel 3 or C. If you purchase a wireless phone by mail, state which channel you wish. You may not get what you want but it's worth a try.

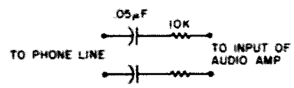


Fig. 1.

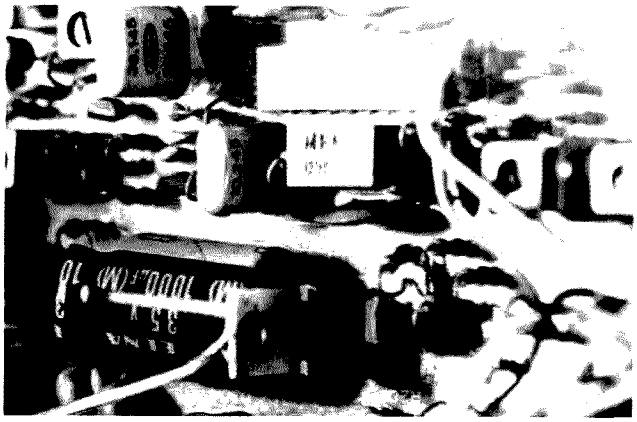
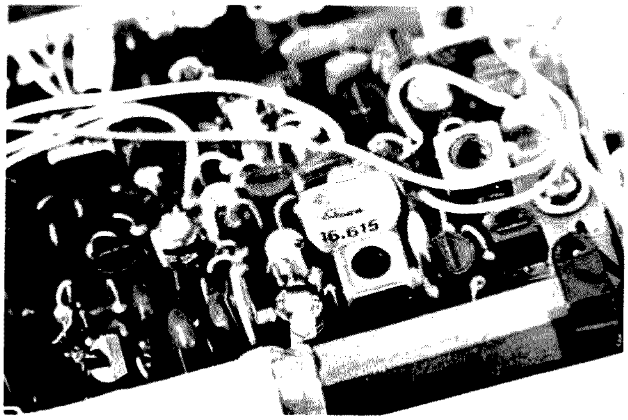
In case you want or need to change frequency on your wireless phone, here's some general information. The transmitting crystal in my hand-held is marked 16.615 MHz but is actually a third-overtone, 49.845-MHz crystal. Crystals can be ordered from Jan Crystals, PO Box 06017, Fort Myers FL 33906-6017. Be sure to tell them the name brand and model of your particular phone. It also would be a good idea to send along the original crystals to ensure that the new ones will be ground to the correct electrical characteristics.

The 49-MHz receiver at the base is a slightly differ-



Close-up of 49-MHz base-unit receiver crystals. The 39.145 crystal is socketed and can be changed easily.



16.615-MHz crystal in hand-held unit is actually a 48.845-MHz, third-overtone unit.

ent story. To receive 49.845 MHz, my unit uses a master crystal oscillator on 10.245 MHz to clack against a socketed 39.145-MHz crystal. This adds up to 49.390 MHz which is exactly 455 kHz (the i-f amp frequency) below 49.845 MHz. Other units may vary.

For the most privacy, you could change your wireless phone to operate on a frequency a smidgeon above or below the five designated 49-MHz channels and never have to worry about someone else with a similar unit making phone calls (either inadvertently or on purpose) through your base unit. However, to keep inside the law, it would probably be better to shift it to a frequency actually "between" the 15-kHz-spaced channels, keeping in mind to stay away from the vicinity of 49.860 MHz. A shift of 5 kHz is enough to keep you safe from similar units.

My hand-held had a crystal-controlled, 1700-kHz receiver. The HC32 crystal was 2.150 MHz which is 455 kHz above the 1695-kHz base-transmitter frequency. The base-transmitter frequency can easily be changed by adjusting a slug-tuned coil so you'll only need to change the receive crystal in the hand-held unit. Shifting the low-frequency link will also give you more privacy and less interference.

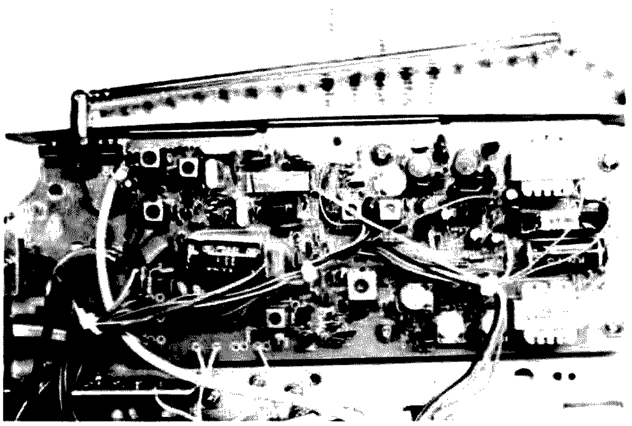
Now take a look at the power cord coming out of your base unit. One side of the zip cord is marked with a white line, small lettering, or a groove running the length of it. This is the "antenna" side of the 1700-kHz base transmitter. Keep this side plugged into the "hot" terminal of the electrical outlet for better phone range. In my case, it added about 100 feet of extra range.

Conversely, to increase the range of the 49-MHz base receiver, it can be connected to an outdoor antenna. I used a quarter-wave CB ground plane with half the radiator removed. A six-meter antenna would work fine and so would an allband scanner antenna, although these are more costly. You can use a clip lead connected between the base unit's telescoping antenna and the center of the external antenna's coax or open the base unit and solder a short length of shielded cable to the PC board and terminate it with the proper in-line female connector. Using an external antenna is all the more reason to shift the 49-MHz link to prevent unauthorized use of your phone line through the base unit.

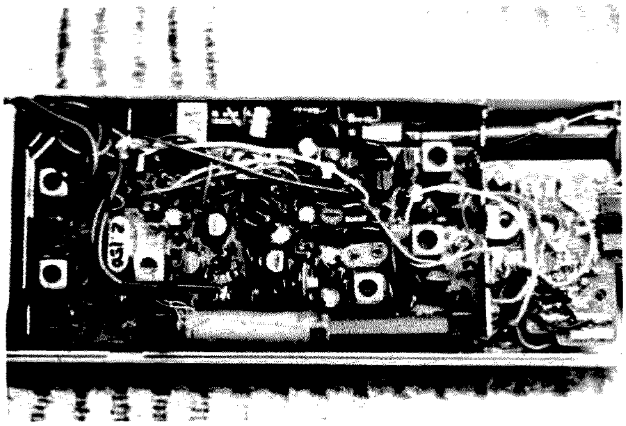
By the way, you can listen to the 1700-kHz side of the conversation on most broadcast-band AM radios if they have a bit of over-tuning on the high end of the dial. I've monitored my own base unit on two different hi-fi receivers successfully and have heard a couple of other neighborhood phones as well. You can hear both sides of the phone conversation on these frequencies. Just remember, the signals are FM so you'll have to use slope detection by tuning a bit to either side of the FM carrier.

I turned my base unit into a 49-MHz receiver by soldering a cable to the circuit board and running it to the input of an Archer 277-1008 amplifier sold by Radio Shack. There are four terminals on the circuit board connecting to the phone lines. To find the correct two terminals, first disconnect the base unit from the phone lines. Put the hand-held on "talk" so it is transmitting on 49 MHz. Using two clip leads, experimentally hook up two terminals at a time to the input of any audio amplifier until you get a loud squeal from the feedback between the hand-held and the audio amplifier. Once you've found the correct terminals, install the circuit in Fig. 1 between the base unit and audio amplifier. This prevents any loading on the phone line when you plug the base unit back in. It also allows you to listen in on any phone call using the audio amplifier. Now when you have the base unit on but disconnected from the phone line, it is a 49-MHz receiver for one of the five channels.

I also tapped into the base unit's regulated power supply to power the audio amplifier. It provides about



PC board in base unit. The 1700-kHz transmitter frequency can be varied by a slug-tuned coil.



PC board in hand-held unit. On the left of the board is the 1700-kHz receiver crystal, marked 2.150 MHz. In the middle is the 49-MHz crystal socket.

10 volts. The collector of the regulator power transistor (the "tab") and one side of the filter capacitor provide the power. Use a voltmeter to find the correct polarity. I added a jack to the amplifier speaker's battery terminals for quick connecting to the base's power supply. There's not much to it.

The wireless phones are quite nice to have when you aren't near a "real" phone. The only other suggestion to purposely curtail reception by others on the 49-MHz end is to keep the telescoping antenna on the hand-held extended just enough for clear communications—usually, you won't need to extend it at all when you use the unit in the house. ■

Modern-Eyes the S-Meter

Here's how to de-strain your baby blues by adding a simple LED readout.

Gordon W. Patterson
12-4215 Meadowvale Drive
Niagara Falls, Ontario
Canada L2E 5W8

Photos by Tish Cox

Having recently acquired a Realistic Patrolman 6 salvaged from the neighborhood garbage can, I decided that some form of indication was needed when I was tuned to the local repeater, VE3NRS. The only thing missing from the receiver was a band-selector shaft. This was easy enough to fix, and the receiver works great! I also use the receiver to listen to a local net which meets on 144.6 AM every Sunday night at 0230.

Various magazines were searched for an S-meter circuit; those found were unappealing. Then one day I stumbled across an LM3914 IC and my troubles were over. The LM3914 chip is a monolithic IC which senses analog voltage levels and drives up to ten LEDs, providing a linear analog display. This IC requires no resistors between the IC and the display, as the current drive to the display (LEDs) is regulated and programmable. The display can be used as either a bar or dot array. Another option of the LM3914 is operation from as little as 3 volts to a maximum of 18 volts. The IC can drive LEDs of many colors.

Theory of Operation

In operation, the device senses changes in the voltage applied to its input. The unit I built has an input range from 0.13 to 1.3 volts. So with each increase of .13 volts, the IC will turn on an LED in sequence.

Referring to Fig. 1, R1 controls the current going to the LEDs. With a value of 1000 Ohms, current through R1 will be 1/10 LED current, which gives a value of about 10 mA for LED current.

Take a look at Fig. 2. This is the internal operation of the LM3914. The 1.2 reference voltage is used for comparison of the voltage which is applied to the input. With each increase of .13 volts of the input signal, a resulting comparator will turn on and produce an output at pin 1 and pins 10 to 18 which will drive an LED. The LM3914 could be replaced with a handful of LM339s, but it would seem senseless since cost would rise and there would be more work required in constructing the circuit. Also, more discrete components would be needed.

In Fig. 1, you will notice that the display can be placed in the bar mode by connecting pin 9 to the Vcc

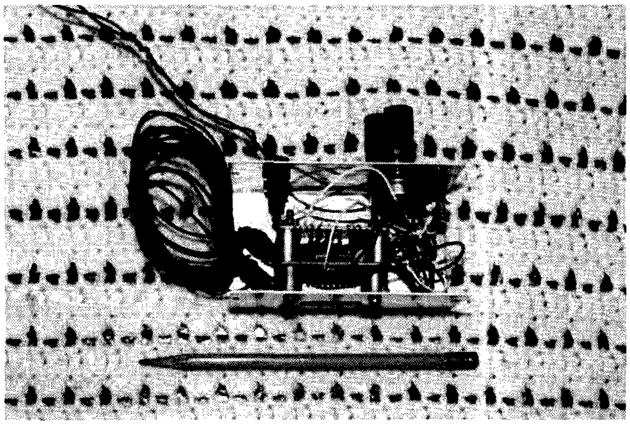


Photo A. The S-meter—inside view.

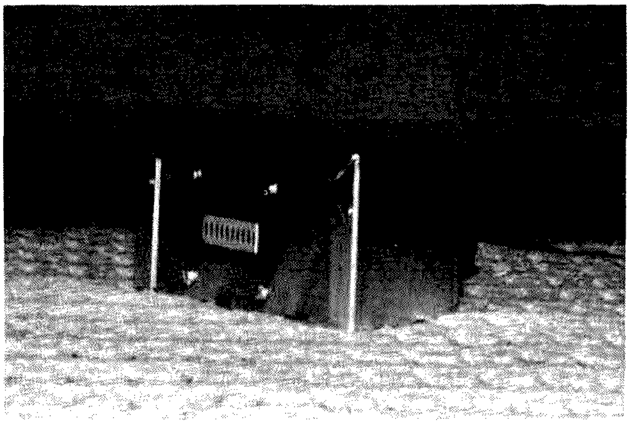

Photo B. The S-meter—outside view.

line, or in the dot mode by connecting pin 9 to pin 11. The 2.2-uF capacitor between pin 2 and the LED anode line is added only if the display flickers during operation.

Construction

The circuit was constructed on a PC board made by Radio Shack. The board was cut in half so that the LM3914 could be mounted behind the LED display using standoffs. The LED display I used was an MV57164 also purchased at the local Radio Shack. If you want to save money, you can use ten individual LEDs. Also, I recommend using DIP sockets for the display and the IC.

The entire project was placed in a 4″×2¼″×2¼″ chassis box since there was no room on the front panel of the receiver to mount the display. If you mount the display in a box, you will have to file a rectangular hole to accommodate the display.

I used banana jacks and plugs for the input, bar-dot display, and power connections. I mounted all of the latter on the back of the chassis box, including the calibration pot. However, you can select whatever you think is better. I used ½-inch spacers which brought the display to mesh nicely with the chassis.

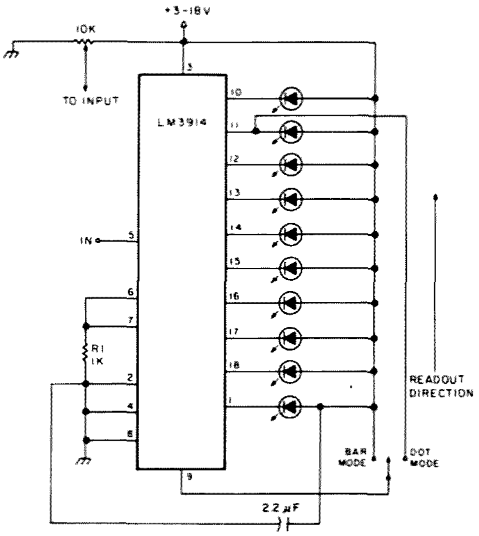

Fig. 1. Schematic.

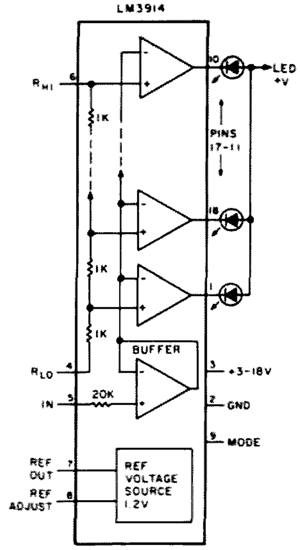

Fig. 2. Circuit of the LM3914.

Hookup

Once the project is finished, the only external connections needed are power and the input connection to the receiver's discriminator circuit. The power can be supplied from the receiver. Once this is accomplished, apply power to the unit. The display will be either on or off.

Now turn the receiver off but keep the supply to the project on. Adjust R2 until the first LED lights, and then back off on the pot until the LED goes off. Now apply power to the receiver and watch the display. Tune around the band a bit to see the reaction of the display. If you can't get the display to light, check to see that you have it in the circuit properly.

Conclusion

I've included a couple of photos of the completed unit so you can see what the device looks like. No longer do I have to tune by ear when I listen to the local repeaters. I'm already in the process of building another "Modern S-Meter" for an old, somewhat tired DX-160.

So heat up them soldering irons! ■

Parts List

Part	Description	Price
IC1	LM3915	$ 5.99
MV57164	LED display	5.99
R1	1k, ½-W resistor	.05
R2	10k pot	1.00
C1	2.2-uF, 25-V electrolytic cap	.50
A1	18-pin DIP socket	1.19
A2	20-pin DIP socket	1.29
PCB	Printed circuit board	2.29
	8 ½-inch spacers, @ .05	.40
	5 banana jacks, @ .35	1.75
	8 nuts/bolts, ⅛ x 2 inch, @ .05	.40
		$20.85

All of the parts are listed with Canadian price, and can be purchased from Radio Shack.

Let's Have More Hams

Part I: How to organize and run a Novice class.

Every amateur-radio club attempts, or at least should attempt, a Novice class. Many of these classes wind up in a shambles very soon, however, as attrition reduces them to a small number of hardy hangers-on.

"Oh well," you say, "it's just separating the men from the boys, right?"

Wrong! You are throwing away many potential hams who wanted to get their licenses. They would not have taken the time to show up in the first place if they were not interested. That screening process has already been done for you, so there's no need to do it again.

So, what can be done to better organize and then run a Novice class which has the potential for graduating 100 percent of those who start? Plenty, and most of it has to be done before the first student walks in and stares at an instructor or a chalkboard.

Planning

Planning has to be done well in advance, and several questions have to be answered. What theory and regulations teaching system or syllabus will be used? Which method of teaching the Morse code will be utilized? Where will the class be taught? How often will the classes meet? Who will the instructors be? How will the class be publicized? These are the most important items, and this article will delve into each briefly.

Theory and Regulations

Any attempt to teach radio theory and regulations without an organized syllabus or teaching plan is doomed to disorganization. The plan must cover the entire subject matter and state exactly what must be taught on which day and in what order. Do not delude yourself into thinking that the FCC syllabus is sufficient. A student teacher in college presenting that document to his teaching supervisor would be laughed out into the hallway with detailed instructions about how much more work was required before he should show his face again.

Break down each class session into precise time periods during which certain matters will be taught. Fig. 1 shows a bare outline for one two-hour session.

1900-1910	Introductions, names, etc.
1910-1920	Questions and answers
1920-1940	Resistors and capacitors
1940-2000	Ohm's Law, E = IR, P = EI
2000-2010	Break
2010-2030	Morse code practice
2030-2045	Review of Ohm's Law, practical problems
2045-2100	Questions and answers

Fig. 1. Example of a basic teaching plan.

Each instructor should have an even more detailed guide, showing exactly what will be presented to the students, both orally and visually. Fig. 2 shows a good example of what an instructor's detailed lesson plan might look like for part of the section on Ohm's Law from the basic teaching plan shown in Fig. 1.

Use a chalkboard, overhead projector, slides, demonstrations, or whatever you have available. A visual presentation has far more impact on getting an abstract idea like voltage or current across to a wide-eyed bunch of students who have barely even heard of a resistor, let alone Ohm's Law.

There are several Novice teaching systems available, including those by Radio Shack and Heathkit®. The ARRL "Tune in the World" syllabus is a good, readily available course. It is complete and easy to use as a teaching guide, and it comes complete with a textbook. However, regardless of the syllabus used, be sure it is complete, comprehensive, and presented in a logical sequence. If Extra, Advanced, and old-timer Generals aren't sure if it is a logical sequence, take it down the street to your local junior high school science teacher. Remember, you are teaching people who are not hams and may never have seen a ham radio.

Morse Code

The requirement for learning the Morse code has driven off more potentially outstanding amateur-radio operators than any other barrier. While I am not personally convinced that the code is a valid requirement for a modern ham, it is nonetheless a legal requirement and must be taught. So, why not make it as painless as possible? Do not allow it to screen out scores of new hams before they have had a chance to get started.

After searching the market for Morse-code teaching methods, I have run across two distinct varieties. Both teach the code at five words per minute, initially. However, one teaches each character or letter at 5 wpm (slow style), while the other teaches them at 13 to 16 wpm (fast style). The slow style has characters going by painfully slowly, while the fast style zips them by briskly. The fast style leaves enough time between the characters to give an overall speed of 5 wpm. In my personal experience, there is no question about which is best. The fast style is far superior for learning the characters, and eliminates the necessity of relearning the characters at a higher speed later.

Among the fast styles, there are two subcategories of teaching methods. One of them teaches the letters by groups of dits (E, I, S, H, 5), then dahs (T, M, O, 0), then on to the other letters related in much the same way (ARRL's method). The other starts with A and N, then adds T and E, M and I, and so forth, teaching in groups based more or less on opposites (*73*'s method). I can see merits in both methods and have used them almost interchangeably. The key to the whole thing is teaching the characters at a high speed (13 to 16 wpm), gradually bringing the overall speed up once the characters are learned. Oh, yes. . . if you want them to copy a 5-wpm test without any trouble, teach the code up to about 7 wpm to allow for the jitters.

Now, how to test for code comprehension. Send a 5-minute typical QSO, complete with abbreviations, numbers, and punctuation, and see how they do. You can either give a written test, as does the FCC, or just see if they can get a solid minute's copy out of the whole thing. Be consistent and let them know what you expect from the beginning. You are the one who has to sign on the dotted line and guarantee to the FCC that the individual can communicate in the Morse code at 5 wpm.

One big problem nearly always encountered is a shortage of code-practice oscillators (CPOs). If the student doesn't get one in the first few weeks, he will have a hard time keeping up. The club can help out in several different ways. One is to have all those unused CPOs "donated to the cause" and give them to the prospective Novices. A better way is to have each student build one right away. Take part of the students' registration fee ($5.00 is more than enough) and buy the parts to make a simple oscillator. Club members can make up some PC boards ahead of time and provide the students with a few soldering irons and a couple of helping hands. By the end of the first session, each one will have his/her own private CPO. Another quicker alternative is to buy up a bunch of Radio Shack's code oscillator modules (cat. #20-1155) for about $3.30 each. These modules will require the addition of a speaker, a battery, and a key.

Another inexpensive and easy-to-build code-practice oscillator is shown in Fig. 3. This project should be easily within the capability of the club to help the new student build. One would need to add some sort of mounting for the components, probably a small PC board, wire, a flexible two-strand cable to connect the key, a couple of screws to hold the speaker, as well as any miscellaneous items the builder would want to add. The tone isn't the best, but it is adequate. Probably some variation of the resistors could improve things.

This does not include the key. Radio Shack has a pretty decent one for $5.95. The circuit draws about 30 mA at 9 volts with the key down. A 9-volt battery should provide several hours of code practice. The current could probably be reduced some by substituting a 1-uF capacitor in the speaker lead. (I didn't have one.) The circuit draws no current when the key is open, so there is no need for a power switch.

Ohm's Law, E = IR
E = electromotive force measured in volts
I = current measured in Amperes
R = resistance measured in Ohms
Draw basic circuit diagram on board
Show relationship between variables when one is changed
Do some formula solutions
Example: Voltage = 12 V
Resistance = 2 Ohms
What is current? Answer: 6 Amps

Fig. 2. Sample instructor teaching guide.

Instructors

During my early Naval training at Officer Candidate School in Newport, Rhode Island, I remember one particular leadership lecture. The school had brought in an old captain, whose name I have since forgotten, to talk to us about the mysteries of command and leadership. I remember very little of what he said, except for three rules:

Know your stuff.
Take care of your men.
Be a man.

These three rules, which I am sure he borrowed from someone else, summarize a lot of things about what an instructor should be.

Know your stuff. Choose an instructor who is very well versed in the material which is to be taught. Even a six-year-old will see right through a faker within five minutes.

Take care of your men. The instructor needs to be constantly in touch with how well the students are grasping the subject matter. Be demanding but personable—never be reluctant to drop back and teach it all over again with a smile if it did not work the first time. If at all possible, use a different approach. If they didn't understand, it is quite possible that the technique was faulty or the examples didn't make sense.

Be a man. Do not pretend to be Mr. or Ms. Know-it-all. If you do not know the answer to a question, admit it right off and make a note to bring the answer back next class period. The students will not think any less of you if you do not know one or two things. Also, have the moral conviction to stand up for some standards in what you expect of the students to pass the course. Do not let someone get by with what you know very well to be poor ability in Morse code, just because you are afraid to tell him that he has to work harder or do it again.

Teacher-student ratio. Limit the classes to ten or twelve students for each instructor. By keeping the teacher-student ratio down, each teacher can be personally involved with the students' progress.

Class frequency. In many cases, how often the class can meet will depend on how often the classroom is available. Barring this restriction, however, twice a week is best. Once a week can be made to work, but the time between sessions makes the classes almost unrelated. If classes meet more *often* than twice a week, students (as well as instructors) will start dropping out from time starvation. Remember, ham radio is *not* the only thing in the world.

Publicity. If no one knows that you are going to have a class, it is hard to gather a crowd. Assign one person (the club's public-relations chairman) to get the word out. Draw up some flyers and get them put up around town. Be sure they get to the junior and senior high schools. If one of the club members works for the local school district, tap him to be the special agent for getting those youngsters notified. They are the best potential hams going because of their unbridled enthusiasm. Most of these kids play around with computers routinely, so electronics is nothing new, and the idea of communicating fascinates them.

Get a spot on the public-service announcements of your local TV and radio stations. Don't just drop off a note and leave; get ahold of news reporters and bend their ears for a while. Tell them they can film the class for a personal-interest story.

Then, don't forget to look for prospective students in your own backyard: wives, husbands, sons, daughters, friends at work, next-door neighbors. All of these people have probably been introduced to ham radio by knowing you. Heck, offer to pay half their registration fee with the other half kicked back if they pass the test. (I hope you're not in this game for the money.)

Miscellaneous Planning Considerations. Choose one individual to be the Novice-training coordinator. Then choose a second person to be the Morse-code instructor. Once this is done, you have gone a long way toward ensuring consistency of instruction. The training coordinator must ensure that continuity is maintained between different instructors. The Morse-code instructor will ensure that the students aren't confused by a myriad of different pet methods of learning code. It's hard enough for the students to learn the code without having to fight their way through several different instructors' ideas about how it ought to be done.

For each student, assign a club member to be his "Elmer." This individual should be present at the first session, and then he should regularly contact the student throughout the progress of the class. This personal touch is essential to maintain interest, especially when initial frustrations are encountered. It also helps when the time comes to set up the first Novice station, or to answer the frantic telephone call at 9:00 pm concerning the unexplained interference to channel 3. *Get your Elmers out.*

The First Class Session

The basic rule for the first class session is to relax the students and introduce them to amateur radio pleasantly. Set up a demonstration of 2m FM, HF CW, and SSB, and throw in some RTTY or ASCII and even some SSTV if it's available. Have the gear set up and tested well in advance with club members planted out in the community for guaranteed contacts.

Make introductions quickly. Pair students off with their Elmers, talk about ham radio a lot, discuss how the course will be run, and build that code-practice oscillator. End it all with the demonstration, letting the students get on the air a bit.

I watched the glazed eyes of several students after they walked out of a first session in which they had been hit with E = IR, P = IE, 468/f(MHz), and a list of the Novice operating frequencies. They had little idea of what they had been given, and they felt they were already in over their heads.

So, bring them in gently, then begin talking about the more substantive material in session number two. By then, they have had a chance to talk to their Elmers, get in a bit of code practice, read the text book, and raise a few good questions. Things will be off to a better start with much less early attrition.

Keeping It All Flowing

Once the initial excitement has died away, it is down to the work of teaching and testing. If you have more than one instructor, the class coordinator must constantly be sure that the teaching is consistent between classes. Keep track of each section's progress. If one student seems to be dropping behind, get the assigned Elmer onto the case right away. The Morse-code instructor should be sure that all practice is done consistently and should check each student every class period. Tests should be available every class session for anyone feeling he is ready. Emphasize the importance of getting that code out of the way first.

Wrapping It All Up

At some point, all the material will have been taught, and everyone will have been given an opportunity to learn the code.

Those who have not passed the code by the end of the program need to have special attention. In most cases, these people are the "Nervous-Nelly" types, who get the jitters each time they take a test, or who have convinced themselves that it is all too hard. With these people you have to pull out all the psychological stops. Be sure these people get with their assigned Elmers. Keep encouraging them. Above all, keep them with other hams and try to maintain their interest.

You will lose some, perhaps, but don't let it happen because you just let them slip away, frustrated. Stay in touch with them, and let them know that it is always possible to try again. It is often easier the second time around.

If you publicize well, and in the right places, the people will respond. Then, by managing the resources available to the local club and by spending a lot of preliminary time in planning and organizing, you can graduate most anyone who sincerely tries. Let's get some more good hams into our community. They are out there just waiting for you to give them a chance. ■

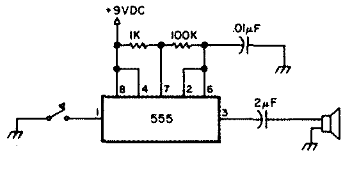

Fig. 3. Inexpensive code-practice oscillator.

CPO Parts List

555 timer	$ .34
1k	.05
100k	.05
.01 uF	.08
2 uF	.13
2" speaker	1.25
9-V battery	1.00
battery lead	.10
case	1.99
	(Radio Shack)
Total	$ 4.99

Thanks to WAØPBQ, my dad, for the circuit design and description.

Let's Have More Hams

Part II: How to take and pass FCC exams.

Take it from me, upgrading your amateur license is a major task. Think about it. First there's the time spent studying, then there's the trip to the exam point (often far away), and finally there's the exam itself.

I know. I've recently returned from taking the Advanced exam. For me, the entire process was fun because I passed the first time. Unfortunately, for some in the room it wasn't fun. They failed. And for some it was their third time.

Despite all protests otherwise, the real reason applicants fail the exam is inadequate preparation. When you go for the written, you must know the material *thoroughly*.

This is going to be even more important in the future with the recent changes allowing volunteer examiners. You can be sure that the new exams will not be compromised easily. Some book publishers may find themselves out of business. The net result will be an increased emphasis on understanding and a reduced reliance on question memorization.

Surprisingly, most, if not all, study materials overlook one important phase of preparation—that of preparing your test-taking skills. Remember, the FCC determines your qualifications by administering a test. It's unfortunate but true that a person can know the material but still miss questions because of poor test-taking skills. My goal in this article is to improve your skills. A little time spent on brushing up here could make the difference between passing and failing.

The First Mistake

Mistake number one usually comes long before the applicant walks through the examination-room door. Sometime after he begins studying for his first license, the ham-to-be learns that all FCC exams are multiple choice.

A feeling of pleasure and relief overcomes the neophyte. After all, he reasons, what could be easier? The answer's right there in front of me. All I have to do is pick it out.

This attitude toward a multiple-choice-type exam is the first mistake. Actually, a well-written multiple-choice exam is not the gift some think it to be. It can be one of the most difficult exams to bluff your way through. Multiple-choice questions are written to require a sound knowledge of the covered material. Let's look at Fig. 1, which is sample question number one, and use it as an illustration.

In the circuit shown, what is the value of R1?

A) 24.2Ω **C)** 4.8Ω
B) 120Ω **D)** 48Ω

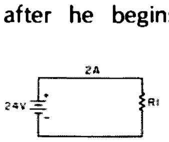

Fig. 1. Sample question one.

In order to answer this question, we have to know Ohm's Law. To get the answer, you must divide the voltage by the amperage. In this case, B is the correct answer: 120Ω.

If you're well grounded in this basic law, it's no problem. But what if you are weak on this point? What if all you could recall was that Ohms, volts, and Amps are interrelated and that you can get one by multiplying or dividing the others... somehow or another. If you multiply volts times Amps, you come up with 4.8Ω. This answer also is listed (C) as a possible choice. No amount of inductive reasoning can help you eliminate a wrong answer like this. You must *know* the material.

The Role of the "Good-Looking" Wrong Answer

FCC exams have often been maligned as being unfair, tricky, or as not really testing your knowledge. Actually, it's not so. The charges stem from the use of the "good-looking wrong answer" in a multiple-choice test. Look back at question one again.

The purpose of this question is to test the applicant's ability to use Ohm's Law to solve basic dc calculations. Therefore, all the answers can be derived by adding, multiplying, or dividing the other numbers in the problem.

What is the simplest form of an amplitude modulation detector circuit?

A) Transistor detector
B) Balanced detector
C) Diode detector
D) Diode series demodulator
E) Diode rectifier

Fig. 2. Sample question two.

How much testing can occur if the wrong answer choices are listed in kHz, pF, or mA instead of Ohms? Very little, of course. If the wrong answer choices are listed in anything but Ohms, the purpose of the question is defeated.

In order to test the applicant's ability effectively, the wrong answer choices must be similar in form and content to the right answer. In the process of keeping the wrong answers from being obvious, the exam writers create the good-looking wrong answer. These answers are designed to be equally as appealing as the right answer. For the individual with a poor grasp of the material who is just guessing, it can be extremely difficult to differentiate the right answer from a good-looking wrong answer.

Exam writers create good-looking wrong answers by taking a basically correct answer and modifying it with a misconception. Here's an important point for you to remember as you're taking your exam. When you're considering the various choices, don't be looking for truth in the answer, *be looking for error*!

All answers will have some semblance of truth in them. Only one will contain no error. The amount of error incorporated in the test answers determines the difficulty of the test. The less error, the more difficult it is to distinguish the right answer from the wrong one.

Let's look at question two in Fig. 2 and use it as an example. Question two is a definition question. The correct answer is C: diode detector. Now look at all the incorrect answers. The words "diode" and "detector" are sprinkled through the wrong answers. They are the truth part. The balance makes up the error part.

It takes a thorough knowledge of the material to answer the question. If all you can remember is that it's "some type of detector" or "it had a diode in it," your chance of guessing correctly will be minimal.

Now that you're aware of these good-looking wrong answers, be careful to stay clear of them on your exam. Don't jump at the first answer that looks appealing. Look at it closely. Remember, you're looking for error, not *truth*.

The Multiple Types of Multiple Choice

Although the whole exam is multiple choice, all the questions won't have the same format. In fact, they break down into three distinct types with a different technique needed to correctly answer each type. Let's look at each of them. My goal is to give you a practical technique for getting what you do know down on paper in the form of a correct answer.

Problem questions. The first kind is the problem question. Question one is an example of this kind. This question provides some information about the circuit and then, based upon this information, asks you to determine the value of some other portion of the circuit. To be able to answer this question, you must be familiar with electronic formulas.

The most important step in correctly answering this type of question is to keep your eyes off the answers. I strongly advise that you cover them with a sheet of the scratch paper provided with the exam. The choices that the exam offers are irrelevant at this point and will bias your thinking if you read them.

Having covered up the answers, read the question carefully. Note all the information given. Your answer must be based on this information alone. Don't read anything into it.

Next, determine what steps you're going to use to arrive at the answer. In question number one you could say to yourself, "I'm going to divide the voltage by the amperage to get the resistance."

Usually the questions are not this easy. You'll find yourself having to do two or three intermediate steps to arrive at the final answer. In the longer problems, this technique really pays off. If you think the problem through in advance, you are less likely to stop short of the final answer or become confused.

The final preparatory step is to decide what is the correct unit of measure for your answer. Is it Ohms, volts, uH, or pF? Determining this now can help you avoid some of those good-looking wrong answers. It's common to find the result of some *intermediate step* listed among the answers. Don't get caught.

While all this seems time-consuming and unnecessary, it's neither. What you've done so far you would have done anyway. The advantage is that you are less likely to make an error if you do all the reasoning in a single step rather than piecemeal as you go. In addition, knowing what you're doing tends to take off some of the pressure. As you relax, you'll probably do better work.

Now start your work by writing down your formula in its symbolic form. It doesn't matter if it's as simple as Ohm's Law. Write it down.

Right now I can hear someone saying, "Hrump! That's dumb. I'll bet Extra-class hams don't write down formulas!"

Well, maybe they do and maybe they don't, but you aren't an Extra (yet). Frankly, it doesn't matter if you ever write one down again after the exam. It is important that you get the right answer this time, and writing it down reduces the possibility of skipping steps in the procedure.

Besides, if you goof, everything's written down on paper in logical order so that you can recheck your work.

Once you've arrived at your final answer (making sure that it's in the same unit of measure that you determined beforehand), uncover the test answers and compare your answer to those listed.

Just a personal observation here: I've rarely arrived at the exact same answer as was listed in an FCC exam. The difference probably lies in where we rounded off very large numbers. Your answer should be close, however. Pick the one closest to yours if you're satisfied you've made no mistakes in your *calculations*.

Does this sound like a lot of work? Actually, it's no more than you would do any other way. What you have done is to force yourself to think your way through the problem first, then to solve it by following a pattern of logical steps, and finally to avoid letting miscues from those good-looking wrong answers bias your reasoning.

Definition questions. The second kind of question that you'll encounter is the definition question. It's just what it sounds like. You must choose a word or phrase from the list of answers that the definition in the ques-

A low-pass filter attenuates—

A) —all frequencies below its cutoff.
B) —all frequencies above and below its bandpass.
C) —all frequencies in its bandpass.
D) —all frequencies above its cutoff.

Fig. 3. Sample question three.

A low-pass filter attenuates—

F **A) —all frequencies below its cutoff.**
F **B) —all frequencies above and below its bandpass.**
F **C) —all frequencies in its bandpass.**
T **D) —all frequencies above its cutoff.**

Fig. 4. Another look at question three.

tion best describes. Question two in Fig. 2 is our example.

Our number one rule here is the same as with the problem question: Don't look at the answers. Cover them with a sheet of scratch paper. They're irrelevant and can only tend to bias your thinking.

Now, with your answers covered, read the definition carefully. While reading, pay close attention to any limiting words such as "only," "all," "most," "always," etc. These words can affect the answer to the question. Make sure you've noted them when forming your answer.

Having read the question, decide (still without looking at the test answers) what *you* believe the answer to be. Now you may uncover the exam answers. Your answer will probably be on the list. If not, there will be one that you recognize as meaning the same. You've found your answer.

Again you have gone through a thought procedure that has forced you to arrive at the answer on your own. The definition-type question is where you are most susceptible to the good-looking wrong answer.

Statement questions. The final kind of question is the statement question. This question differs substantially from the two kinds discussed above. Let's look at question number three in Fig. 3 and explain it.

Question three is composed of the beginning of a statement. Each of the answers forms a completion to the statement. You will be asked which one of the possible answers makes a true statement when coupled to the question. Part of the information needed to answer the question is located in the answer portion, so in this case you must become involved with the exam answers before forming your own answer.

Be cautious, because it's extremely easy to draw a wrong conclusion based on something contained in one of the good-looking wrong answers. As you look at your possible answers, you will find that most of them sound reasonable.

Remember what we said about the good-looking wrong answers being a basically true statement with some degree of error included. The answer that you're looking for here is the *only* one that makes a *completely* true statement coupled with the question. Therefore, you should be looking for *errors in reasoning.*

The best way to handle this question is to treat it as a multi-part True and False question. Look at the same question in Fig. 4. In this illustration we take the question and mentally couple it to answer A; because answer A when connected to the question makes a false statement, we have penciled an F in front of it. The same process is used as we determine that B and C are incorrect. Answer D when connected to the question forms a true statement. D, then, is the right answer.

You are more likely to get the question right if you treat each answer as a separate True-False statement and look for errors in reasoning.

Statement questions can take several forms. Some may have no information in the question. They may simply ask, "Which of the following statements is correct?" This is still a statement question and is answered using the same technique.

Statement questions may also take a negative form. You may be asked, "Which of the following is *not* true?" Special care must be taken to see that you remember that you're looking for the one statement with error. Under the pressure of the exam, it's easy to forget that the question is reversed and panic when you find two statements that are absolutely true.

What To Do When You're Not Sure

It would be wonderful if you had prepared yourself so thoroughly that you knew the correct answer to every question. That's not realistic, though. There are always the tough ones.

Let's review a couple of suggestions that might help when the going gets tough.

First, there's the old standby—skipping and coming back to it later. Usually the applicant hopes that there will be something in one of the later questions to help him answer the one he's stuck on.

This suggestion is highly overrated. Exam writers are on the lookout to ensure that information from one question doesn't answer another. The best that you can reasonably expect is to come back to the original question in a different frame of mind.

Another method of finding an answer to an otherwise impossible question is to rearrange the words in the question. Look at Fig. 1 again.

If you can't remember how to find resistance, perhaps you can remember how to find amperage. With the information given, we can rearrange the question so that we can solve for amperage. Which of the possible answers, when divided by the voltage, gives .2 Amps? Answer B is the only one.

You can do something similar with definition and statement questions. To use this system, look at each of the answers and recall everything that you can about it. Your goal is to eliminate answer choices for which you can recall some other function or characteristic.

Look at Fig. 2 again. Let's assume that you couldn't decide between answers C and E. Perhaps you were unsure because you knew that both were tied in with changing ac to dc. By reviewing everything you can on both subjects, just perhaps you'll recall that diode rectifiers are used in power supplies. Since you can think of another application for diode rectifiers (answer D) but can't think of another use for diode detectors (answer C), then diode detectors is your best choice.

I'm offering no guarantees; nothing is going to give you the answer when you don't know enough. The hope is that one or another of these suggestions may shake something out of the old brain box that you aren't aware is there.

The Follow-Through

You're finished with the exam but not with the chance for a mistake. Like everyone before you, there are probably one or more questions that you're not too sure about. What should you do?

Changing answers is a counterproductive activity.

Here's a hard and fast rule: Don't change your answers unless you either find an error in your calculation or you recall a specific piece of information that makes you realize an answer is wrong. Don't change your answer because you're having second thoughts. Your first impression is usually your best. Leave it alone.

There's one last thing that you should do before turning in your exam. Take a few seconds to relax from the tension of the exam and then go back over your answer sheet. This time you're looking for errors on your answer sheet. Look at each question and then the answer that you put down on your sheet. Is it the answer that you intend to have there? Under the pressure of the exam, you could easily have marked the wrong answer slot on the sheet. Now's the time to check the sheet and correct any mistakes.

The last step? Turn in your sheet and wait for the result. If you've followed the suggestions given here, your exam will be a true reflection of what you know—and that's what it should be.

A Word About Preparation

As I've said before, the key to passing an FCC exam is preparation. You absolutely must know the material. Think about it for a moment. How much real studying have you done? I don't mean reading the Q & A manuals, I mean real honest-to-goodness studying.

Before you waste time and effort taking the exam, consider spending some time, effort, and money on a formal course of study. Not only will it help you get through the exam, it will also make ham radio more interesting.

73, and I hope to hear you on the bands with an "interim" attached to your call! ■

Son of Nicad Conditioner

This intelligent discharger knows when to stop and tells you how much time it took.

I found the "Nicad Conditioner" article by W2KPE (*73*, April, 1981) quite interesting, having previously constructed a similar device. The nicad conditioner discharges a battery pack each time before then recharging it.

I recently needed to construct another for the local security force which was interested in cycling its batteries. Since they already had a battery charger set up to "rapid-charge" batteries, I decided to build only W2KPE's simple discharger (shown in his Fig. 1, reproduced here). Several problems immediately developed with his simple circuit. First, it would not stop the discharge at the desired cut-off voltage; it just turned into a buzzer. And if the battery was accidentally connected backward, the control transistor burned out instantly. My improved circuit corrects these problems and adds a simple timer to make life-testing of batteries much easier.

First, some background for those who may not have read the earlier article. The nicad batteries commonly used in hand-held transceivers have one undesirable characteristic: memory. They tend to remember the way in which they have been used. If they have been used only lightly, or not at all, any attempt to heavily and fully discharge them will result in a quick discharge—much quicker than their Amp-hour rating would suggest. (See Fig. 2.) This is especially true if they have been continuously charged without use for a long period. It has been shown that completely charging and discharging the battery several times (cycling) will erase the memory and restore full capacity.

A single nicad cell may be safely and fully discharged by merely placing a suitable load resistor across it (Fig. 3) and waiting for the voltage to go to zero. This, however, is not suitable for discharging nicad battery packs. If we let the nicad pack discharge to zero, a very dangerous phenomenon can occur. Some of the cells in the pack will discharge to zero before the others, due to mismatch of cell capacities. The cells which reach zero volts first will still have current being forced through them by the others. This will tend to reverse-charge (change the polarity of) these cells. Once a nicad is reverse-charged, it is very likely to short out. If a single cell in a pack shorts out, it will no longer take any charge and can only be rescued by heroic measures.*

To reduce the possibility of reversing any cells, it is good practice to halt the discharge of a nicad pack when its voltage drops to just less

*"Zapping Dead Nicads to Life," K2OAW, *73*, January, 1976.

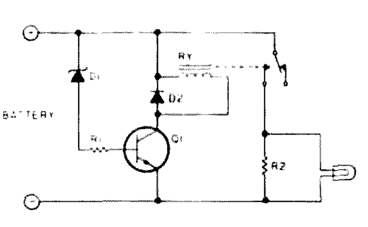

Fig. 1. K2KPE's conditioner/discharger circuit.

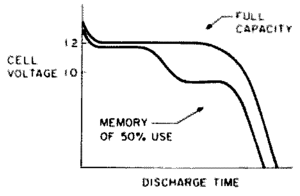

Fig. 2. Nicad discharge characteristics. Note early drop associated with memory.

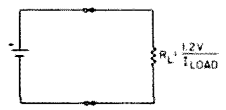

Fig. 3. Single-cell discharger.

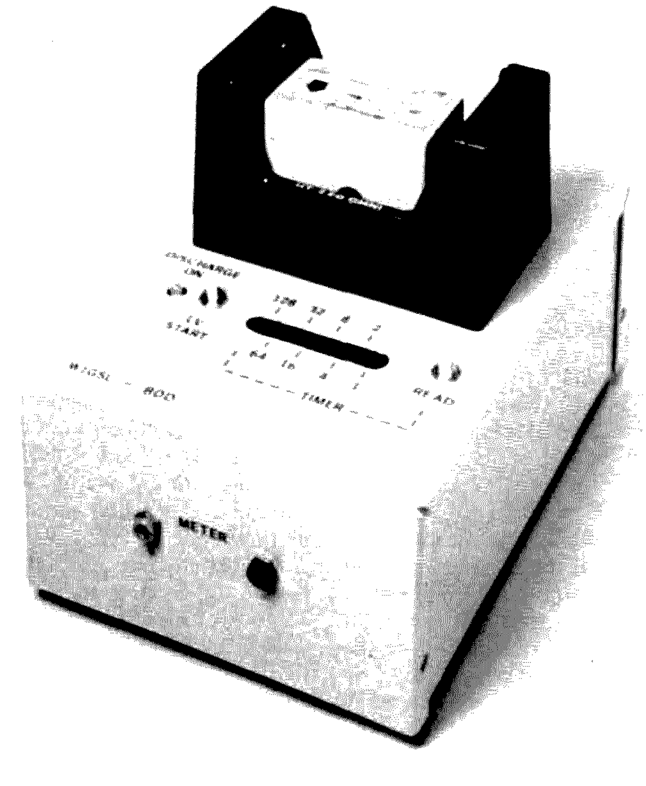

Photo A. The mounting of the discharger is not critical. This version was built into a 3" × 5" × 7" mini box.

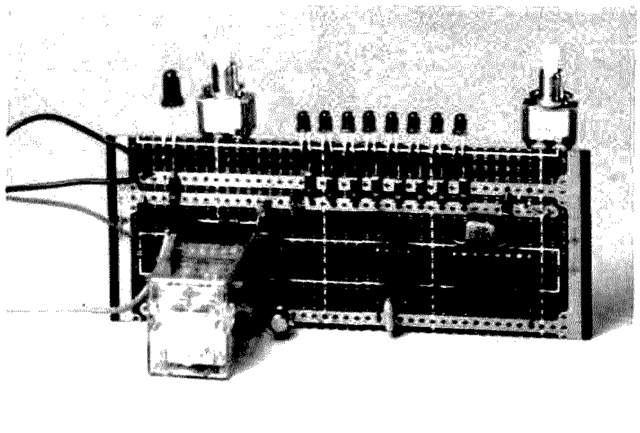

Photo B. The discharger and CMOS timer are built on a piece of IC perfboard.

than 1 volt per cell (10 to 12 V for a 12-cell, 15-volt battery pack).

W2KPE's final circuit, with a latch to start the charger, probably worked just fine. However, his basic circuit has two problems:

1) When the battery reaches the point of discharge ($V_{bat} = V_z + .7$ volts), the relay opens and removes the load. The battery voltage increases when the load is removed, causing the relay to pull in, loading the battery, and the cycle repeats rapidly. This makes a good buzzer to tell you the battery is discharged! However, it leads to a serious life problem for the relay, and I prefer to use an LED as an indicator to minimize noise pollution.

2) If the battery is connected backward, virtually the entire battery voltage is placed across Q1's base-emitter junction. Unfortunately, the breakdown voltage of most transistor base-emitter junctions is less than 6 volts. Once the junction breaks down, there is nothing to limit the current flow and the transistor burns out.

In my improved circuit (Fig. 4), the discharge cycle is started via zener 1. Z1's voltage was chosen so that the discharger will start automatically only with a good, fully-charged battery. Once the relay pulls in, zener 2 is connected. The battery will continue discharging until its voltage drops to less than V_{Z2} + 2.1 V. The series diode, D1, prevents polarity-reversal burnout. D3 keeps R2 from drawing current (through Z1 and Z2) with the relay open.

To use the discharger, first charge the battery in the normal way and then connect it to the discharger. If the discharge LED (D4) comes on, there are no shorted cells. If not, the battery has a shorted cell or may not have been fully recharged. S1 allows the discharge of low-voltage batteries to start. Once the discharge cycle is started, just sit back and wait for the LED to go out. The length of time that the LED stays on is proportional to the battery's capacity.

A discharge timer (Fig. 5) is a very useful addition. It allows a relative measurement of battery capacity without constant attention. The circuit measures the length of time it takes to discharge the battery. To use it, discharge the battery as above. Once the LED goes out, push the "read" button before removing the battery. The number of minutes it took to discharge is displayed in binary by LEDs D5 through D12.

The timer circuit is quite simple. IC1, a 555 timer, runs as a 1/64-minute oscillator whenever the relay is pulled in. Its output drives a 14-bit CMOS counter, IC2. The last 8 bits are displayed by LEDs D5 through D12. R6 and C2 act to reset the count to zero upon battery insertion. The CMOS counter is always connected to the battery. Its current drain is so low that it does not further discharge the battery once the relay opens. As long as the battery voltage remains above 3 volts, it will remember the discharge time. S2 connects the display LEDs only when a reading is desired, so that the battery will not discharge significantly after the relay opens.

I was only interested in relative discharge times, so the timing of a 555 was adequate. A crystal-controlled clock could be substituted if greater accuracy is needed.

Design

Select zener 1 so that V_{Z1} + 1.4 V is just less than the fully-charged battery voltage. Select zener 2 so that V_{Z2} + 2.1 V is your desired cutoff voltage (usually equal to 1 V per cell in the battery).

Zener Diodes

In selecting zener diodes, I ran into two problems:

1) They are made with fairly broad tolerances; usually I had to pick from several to get the exact voltage I wanted.

2) Above 10 volts, they are available only in fairly coarse steps.

Since the cutoff voltage is not critical, this caused no problem with Z2. However, I wanted to set the turn-on voltage fairly accurately. My solution was to stack 2 zeners in series for Z1 (see Fig. 6). The zener voltages effectively add. Because low-voltage zeners are available in finer steps, this made possible a more exact setting of the turn-on voltage.

I started with the existing Z2 (8.2 V) and placed a 5.6-volt Z1' in series, giving an equivalent V_{Z1} of 13.8 volts. This set the turn-on voltage at 15.2 volts.

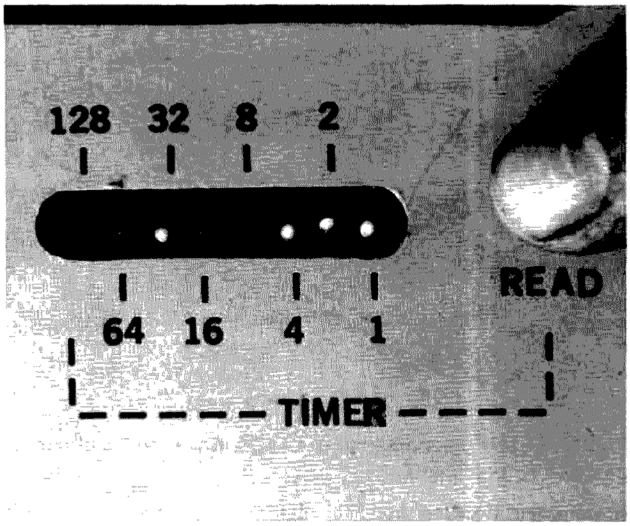

Photo C. Press the read button and see the discharge time in binary form. This battery has been discharging for 39 minutes (32 + 4 + 2 + 1).

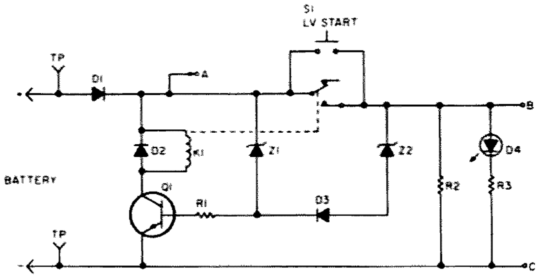

Fig. 4. Improved discharger with polarity protection and shorted-cell detection.

Zener Substitute

A crude but effective substitute for the zeners can be made with several series-connected forward-biased diodes. Eight series silicon diodes will work as a 5.6-volt "zener." Each additional diode raises the voltage by about .7 volts. Any small silicon diodes such as 1N914s will do. While series diodes take up much more room, they offer the advantage of easily setting the voltages with good resolution (.7 V), and at 10 for $1 (Radio Shack part no. 276-1122), they are cheaper and easier to get than standard zeners. The voltage drop across each diode is not very precise, so you may have to experiment to get the exact voltage you need.

The load resistor should draw about the same current as your transceiver does in transmit (R2 = V_{bat}/I_{trans}). R2 will get hot and must be a power resistor. If your load current is fairly low, you may want to include the 20 mA or so that the relay and indicator LED draw in the discharge calculation. Because the CMOS counter can only safely drive 3-mA loads directly, set LED current-limiting resistors R7 through R14 for 3 mA at full battery voltage.

The values in the parts list are what I used for Motorola 15-volt (12-cell), 450-mAh batteries discharged at 300 mA.

Construction

Nothing is particularly critical. I built my unit in an aluminum Bud box, with a sleeve from a charger mounted on top. All of the circuitry except the load resistor is mounted on a small piece of perfboard. The switches support the board and the LEDs are positioned to show through holes cut in the top. The load resistor gets moderately warm, so adequate ventilation should be provided.

An alternative to the CMOS timer is a standard electric clock. If a double-pole relay is substituted for K1, the second pole can control a 110-volt-ac outlet (Fig. 8). An ordinary electric

Photo D. If you don't like ICs, use an electric clock. This discharger uses the guts of an old kitchen clock as the timer.

clock can then display the elapsed time. While this is easier to build and read, the cost of the clock is higher, it would not reset itself, and it is not as portable.

A few words of caution: This device is very useful but it is not a panacea. Nicads can lose capacity for reasons other than memory, in which case cycling will not restore full capacity. One of the prime causes of early failure is overly-rapid charging, leading to overheating and electrolyte discharge. Once a cell's seal has been broken and the internal electrolyte vented, there is no way to restore lost capacity. For this reason, unless you are very confident that your "rapid charger" can limit any temperature rise, I would never recommend charging any faster than at a .1-C rate. This means that the charge current is set to one tenth the milliampere-hour capacity (C) of the battery. For my 450-mAh batteries, this requires a charge current of 45 mA. It takes about 16 hours to fully recharge a battery at this rate. Most manufacturers claim their cells can withstand this charge rate indefinitely without failure.

Nicads have a finite life of only several thousand discharge cycles. Since each full cycle by the discharger represents one of them, it seems best not to allow your battery to develop a memory by fully using it (transmitting) rather than cycling it. Unfortunately, many hams' lifestyles don't permit this. The radio sits in the charger till the weekend, or maybe they prefer to listen most of the time. In these cases, occasionally cycling the battery makes sense, especially before big events when you will need longer-than-usual service.

In summary, nicad batteries need occasional cycling to remove memory effects. Care must be taken in discharging nicad batteries to prevent cell-reversal damage. An improved discharge device is presented for use by those who already have a suitable charger. The improved discharger can detect the presence of shorted cells, is not subject to reverse-voltage burnout, and is silent in operation. A timer has been added to aid in judging battery capacity.

Over the last several years, this battery discharge device and its predecessor have kept my batteries up to snuff and enabled me to salvage several perfectly good battery packs from the reject piles of local commercial users. ■

Perfboard and Soldertail?

Definitely. What is commonly done is never written up (until now) but always appreciated.

L. B. Cebik W4RNL
2514 Dereck Drive, H-1
Knoxville TN 37912

Many ham authors specify perfboard construction for their one-time projects. Then they say almost nothing more about the mechanics of building the circuit on the board. Photos and sketches give us a general idea of the construction methods, but very few articles exist on using perfboard construction effectively. In the spirit of sharing some ideas that have worked well for me over the years (along with some cautions about a few things that lead to trouble), let's see how we can improve our perfboard projects.

Printed circuit boards for transistor and IC projects make construction a breeze. Unfortunately, PC boards are not practical for every project. If an author does not provide us with a source for ready-made boards (and we should not expect every author to make a PC-board layout for his own one-time project), then our willingness to generate our own boards depends on many factors, including time, ability, and desire to design and fabricate the etched pattern. For many small-to-moderate-size one-time circuits, perfboard construction is more practical.

Many types of digital circuits which use few passive components call for wire-wrap techniques. Most ham circuits, however, will require soldered connections. Therefore, we will concentrate on soldertail techniques applied to perfboard construction. Adaptation of these ideas to wire-wrap projects should be easy.

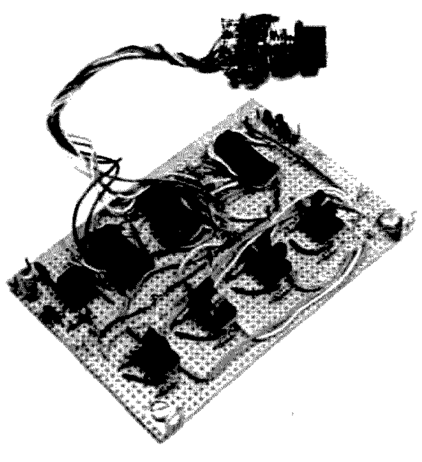

Photo A. An IC and transistor perfboard project with L-brackets for vertical mounting.

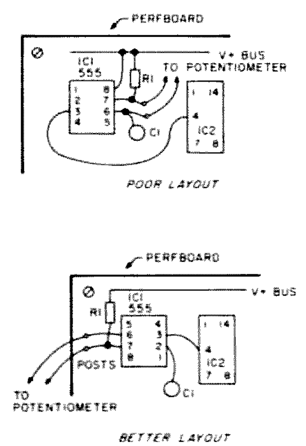

Fig. 1. Planning component layout on perfboard.

Handling Perfboard

Perfboard is generally made from a phenolic material, usually about 1/16th of an inch thick. This immediately limits its utility since it is prone to slight warps in readily-available grades. For PC boards, use the more stable epoxy glass material. For point-to-point wiring on perfboard, the warp is usually not significant in boards up to 5 by 7 inches.

There are several hole patterns for perfboard. Hole separations of .1, .187, and .2 inches are common, but .1-inch hole spacing is the most practical for ICs. For most uses, .042-inch hole diameters are best, although .062-inch hole diameters are available. The smaller holes again work best for IC projects. In fact, the .042-inch holes on .1-inch centers precisely fit the needs of ICs and their sockets. Conveniently, Radio Shack carries this type of board in three sizes: 2.75, 4.5, and 8 inches long, all by 6 inches wide. My own preference is to buy the larger sizes and cut the precise size board my latest project requires.

Phenolic material has some of the properties of mica in that it chips in jagged layers and does not break cleanly. However, with only a little care, it cuts and drills easily. A hack or coping saw with a fine tooth blade cuts perfboard well if you align your cut with a row of holes. Keep the saw blade as parallel to the board as possible, with no more than a 30-degree angle. This technique reduces binding as you pass holes, and the result is fewer broken phenolic scraps. For safer sawing, I clamp the perfboard between two quarter-inch-thick lath strip scraps with a bench vise. The edges of the lath strips are within a row or two of the holes I intend to cut along, which stabilizes the perfboard, and the vise cuts into the wood and not the phenolic. I keep any leftover pieces of perfboard more than one inch square, since I never know when I might need one for a miniature project or a small circuit addition.

Drilling perfboard for screws and other hardware is fairly simple. Use a scrap of wood to back up the perfboard when drilling; this prevents drill-bit snags that can shatter a small board. In general, a 1/8-inch diameter drill bit clears 4-40 screws nicely, while 9/16 is the correct drill-bit size for 6-32 screws. I usually avoid drilling holes larger than 9/16-inch diameter in one try since the large drill bits tend to snag the phenolic material more easily. For larger openings, drill out the perfs inside the desired perimeter until the scrap falls out and then file the material to the final opening size. Another technique is to drill the corner holes, insert a coping saw blade, and saw the opening. You will usually still need a bit of finish filing. One of the advantages of perfboard is that you can add larger openings for relay sockets and other components more readily than with PC boards.

Generally, I try to do all necessary drilling and cutting at one time before mounting components to get in the way of clamping and backing. There are few more frustrating accidents than to have your complete circuit wired, only to watch the perfboard crack or shatter as you try to drill just one more mounting hole.

Perfboard Layouts

One secret to easy electronic construction is paper. The more complete your plans, the more smoothly the project will go together. Even if you are reproducing an author's circuit exactly and have good photos to guide you, paper planning still can save you time and frustration. As inexpensive as many of today's components are, paper is still cheaper.

Example 1. Being able to cut and drill all holes before wiring is a matter of knowing just where they all go and what size they must be. Making some trial paper templates using the real components you have on hand will allow you to determine their size and spacing.

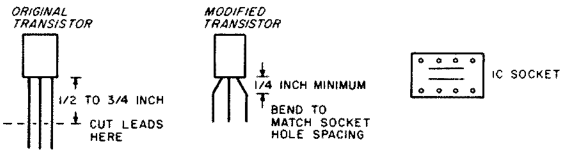

Fig. 2. Trimming transistor leads to fit IC sockets.

In addition, the practice also will let you revise the project and spot errors or neglected needs. You can see how much room you need to clear the mounting brackets or posts, how much space the transformer mounting foot requires, and how much filing you will need to do after cutting a hole for a relay socket. Then you can plan the circuit details so that everything will fit conveniently.

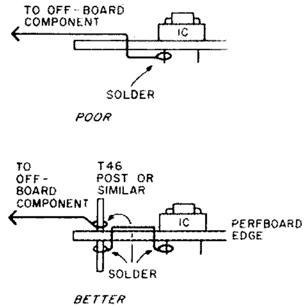

Fig. 3. Using posts for off-board connections.

Example 2. Equally important is the component layout. Fig. 1 illustrates two important considerations: socket pin orientation and component placement. The IC timer, a 555, runs its timing components to pins 6 and 7, while the output emerges from pin 3. Even though we conventionally think of "upper left" as the proper place for pin one, this project calls for an "inverted" placement of the 555 socket. Now the timing components are near the board edge so that leads to the potentiometer are conveniently reached. Too, the output pin is close to the input pin of the next IC.

In digital circuits, socket placement can make jumper wiring either easy or a jumbled nightmare. In counting and readout circuits, you may have several outputs to several inputs. Aligning the jumpers neatly makes short work of the wiring. Having them go over and around an IC to reach the input pins invites undetectable open circuits and other typical building problems.

Leave room enough for the components that go between sockets. Perhaps the best way to be sure your plan will work is to trial-fit all components on uncut perfboard. This practice often reveals unnecessarily long leads and other minor wiring problems before you cut leads. The result is often a revised layout plan. Sometimes, when I am smart enough to have a large extra piece of perfboard on hand, I place all components on the supplementary board. Using this model, I mark the project board for cutting and drilling. Then I move the

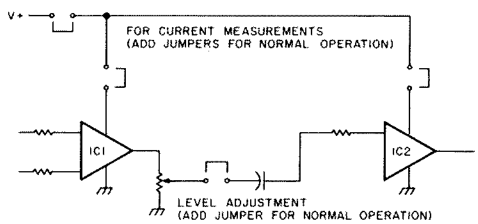

Fig. 4. Using posts to separate circuits for testing and adjustment.

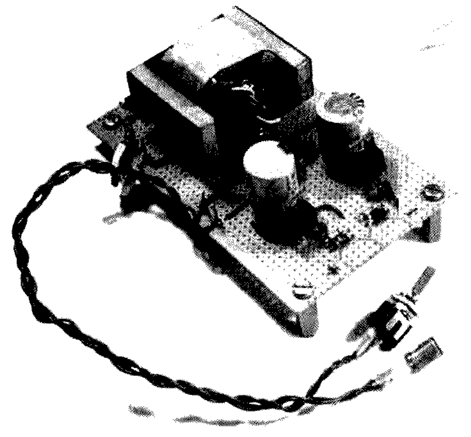

Photo B. A dual-regulated power supply on perfboard supported by posts.

components, one at a time, to the project board. This technique tends to cut considerably both assembly time and errors.

Transferring a layout plan to perfboard requires only a pencil and ruler. Measure and lightly mark the positions for holes. You also can mark the corners of IC sockets and large components for reference. The only precaution here is to eliminate pencil markings completely before covering them with components. Pencil lead is a conductor: not a good one, but good enough to have given me an additional input to a CMOS IC in one project. Erase pencil marks thoroughly just before mounting components.

Handling and Wiring Components

It would be impossible to establish guidelines for handling every kind and combination of components you might encounter, but the following ideas are adaptable to most projects.

First, use IC sockets wherever possible. Use them not only for ICs, but for switching transistors as well. An 8-pin DIP socket will handle two small transistors if you trim and bend the leads as shown in Fig. 2. The advantage of IC sockets over readily-available transistor sockets is that the latter require a fairly large hole through the perfboard. The IC socket rides atop the board with its pins sticking through.

Second, use posts for all off-board connections. Do not run off-board wires directly to components or socket pins. The strain may be too much. Fig. 3 shows

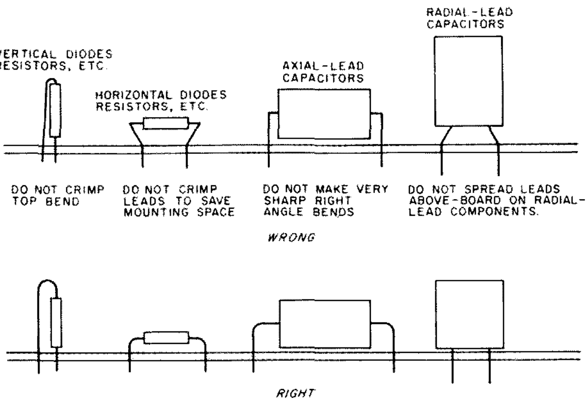

Fig. 5. Mounting components to perfboard.

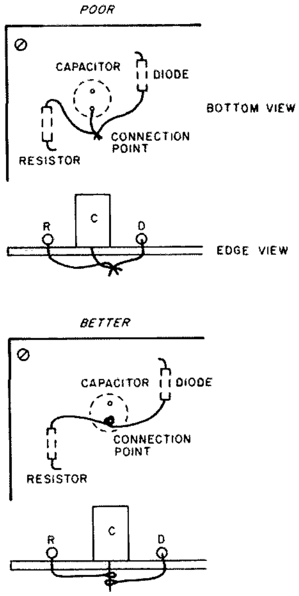

Fig. 6. Under-board component-lead junctions.

the right and wrong way to connect off-board wires. An added advantage of posts is that you can connect and disconnect off-board components from the top side, which makes final assembly of the project a much easier matter.

There are many additional uses for posts, a few of which are illustrated in Fig. 4. You can separate stages of a circuit until after testing by using a pair of posts at the output/input point; a jumper then connects the two circuits for normal operation. This technique permits you to adjust interstage signal levels with no danger of overloading the next device. Paired posts, again jumpered for normal operation, also permit current measurements during the test phases of a project as well as during troubleshooting. I prefer Vector T-46 wire-wrap posts, available through Jameco and other mail sources. The T-46 extends .4 inches above the board and .56 inches below. Its square shank and flare give it good holding power in the perfboard hole. After all soldering, trim the above- and below-board lengths. Below-board, be sure that

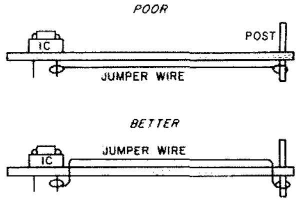

Fig. 7. Mounting jumpers on perfboard.

the post does not touch the chassis or cabinet base. Above-board, cut the post to the height of the tallest circuit component. Wire cutters do the job nicely.

Third, do not crimp components when bending their leads. Some builders prefer to top-mount all components. For this technique, Vector T-42 posts (or similar) permit soldering up to about three leads per junction. However, this method usually requires more space than making direct connections with component leads bent to pass through the board. Fig. 5 shows some right and wrong ways to handle components such as resistors, diodes, and capacitors. Axial-lead components such as resistors require curved bends to avoid eventual lead breakage. Often this takes one more hole, but that is a small price for circuit reliability. Where space is at a premium and component interaction is not a problem, vertical mounting is practical. Wherever you take care in smoothly bending component leads, you will encounter fewer cases of component strain or breakage, even if your layout does not permit instant solder support.

Fourth, when you use component leads to make connections, decide in advance for every junction which lead will serve as the key or post lead. Fig. 6 illustrates the idea. The capacitor lead serves as a post to which the resistor and diode connect. The reasons for choosing the capacitor lead

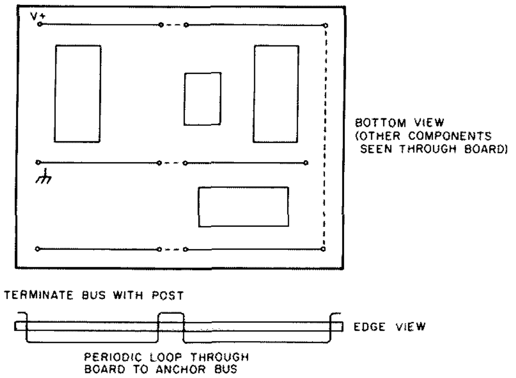

Fig. 8. Perfboard power and ground buses.

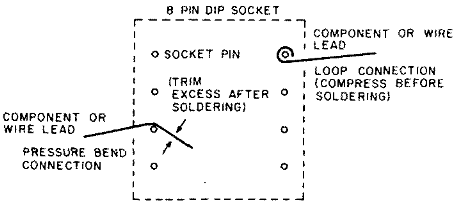

Fig. 9. Soldering leads to IC sockets.

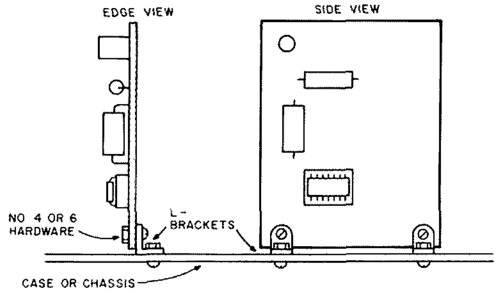

Fig. 10. Mounting single perfboards vertically.

in this example are three. The capacitor lead is the fattest and strongest and thus makes a better post. Too, the capacitor is permanent, whereas the resistor may require another value after testing the circuit. Finally, the capacitor can stand soldering heat somewhat better than the diode.

This case gives only a small sample of the reasons why one or another component may become the junction post; each will have its own rationale. Nevertheless, avoid bringing leads from many directions and simply twisting them together. The under-board layout may be as crucial to reliable circuit operation and ease of revision as top-board component placement.

Fifth, run jumpers topside and through the board at their ends, as shown in Fig. 7. This technique serves several useful purposes. It permits you to trace wiring after the board is mounted. It also takes the strain off the jumper wire, especially if you happen to snag it during construction. Standardizing on top-wire runs also reduces the chances of losing track of jumpers while building. Although excessive looping of jumpers creates an unsightly project board and potential trouble in sorting through the maze, do not put excessive strain on the wires to pull them flat against the board. Leave enough slack to prevent wire breakage, either immediate or later. Then press the wires into place.

These simple guidelines to component handling are mostly matters of common sense. You can add to the list according to your own building experiences. Unfortunately, we often forget these rules while building, usually through either haste or distraction. There is nothing like a soldering iron burning a hole in the test bench to cause us to mishandle a component. If we could only remember which component we were installing during the incident, we would know the first place to look when the circuit malfunctions. If you do not believe it happens, I have two look-alike IC voltage regulators, one positive, one negative, that I once installed under just such conditions. That neither works is proof that I put each where the other should have gone.

Wiring Perfboard Projects

Wiring and soldering a perfboard project can be one of two things: easy or frustrating. Easy wiring requires that we figure out the best way to handle the peculiarities of attaching components and wires to a phenolic board with a hundred small holes per square inch. I wish that I had known what I now know (through experience) back when I miswired my first perfboard.

No. 18 copper wire is the largest that will fit through the .1-inch holes of IC perfboard. For most purposes, No. 18 wire is too large for all but heavy current buses, such as voltage and ground lines on a TTL project. No. 22 or 24 solid hookup wire works best for most wiring. Anything smaller grows hard to handle and solder. We can make off-board connections with stranded wire of the same size.

If we have made a good layout plan, the wiring task should be straightforward. For non-rf projects, I usually begin with voltage and ground buses, arranged as shown in Fig. 8. Long runs pass above and below the board at least once to anchor them in place. Rf projects that require large areas for the ground plane may not be the best projects for perfboard techniques. For dc and lower ac frequencies (up to a few MHz), perfboards and buses work well. Jumpers provide voltage and ground connections to the individual components.

Wiring IC sockets presents problems to many builders. Whether working with PC or perfboard, we manage to lose the sockets as they fall off the board the moment we turn it over to solder. There are many tricks to hold the sockets in place. If there will be unused pins, bend them inward so that the socket lightly grips the board. Some builders put a tape loop under each socket to secure it during construction. Alternatively, you can use a small flat box on which to lay the inverted board for the first socket pin solder job. Whatever the technique, solder all the power and ground jumpers first; this will lock the socket in place for the rest of the project.

The traditional rules of soldering state that every solder joint should first be a solid mechanical connection over which we then flow solder. The solder seals the joint, ensuring a long-lasting electrical connection between wire and terminal. PC boards, of course, violate the old rule as a matter of course. Component and socket leads pass through the holes and, in fact, may not touch the pad. Solder, electrically and mechanically, connects the two. So long as we do not exceed certain weight and vibration limits, the connection will be good for a long time.

Perfboard construction requires that we connect jumpers and component leads to socket pins. Fig. 9

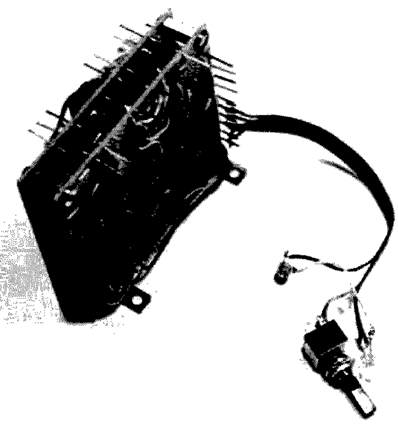

Photo C. A two-board IC and transistor project ready for vertical mounting.

shows two common techniques, and most builders use both in the course of wiring a single IC socket. No. 22 or 24 wire will bend in a loop around IC socket pins with room to spare for the loop to the next pin. However, circumstances often dictate that the partial-bend connection is most practical. Ensuring a good connection is a matter of making sure that the wire in fact touches the socket pin with natural tension before soldering. Unless the lead is under considerable stress, the connection will hold indefinitely. Use a small jeweler's awl to test each such connection before being satisfied that it will hold.

Whatever the construction method, small components used in modern circuits require careful handling. Radial-lead capacitors, such as the small electrolytic type, should be flush with the board. Unless we are careful, they will fall out of position when we flip the board to solder. Resistors, disc capacitors, and diodes should be close to the board, but not necessarily pressed too tightly lest we crimp the component lead. In many cases, the lead is stronger than the component itself. Where this is true, let the lead support the component. Diodes and transistors are sensitive to solder heat, so care is in order. Being sure that the component is mechanically well connected ensures that we can solder quickly with minimum heat. Earlier figures showed the techniques for handling jumpers and off-board connections. Finally, never solder an IC or transistor socket with the device in place.

There are two methods for wiring and testing a solid-state project. One is to wire and test each stage, one at a time. This permits ready circuit revision in early stages before component space has disappeared. For many types of IC projects, it is more convenient to wire the entire circuit and then test the stages by plugging in one or two ICs at a time (with power off and capacitors discharged). With either method, it is safer to remove ICs while making circuit additions or revisions. The IC that will fry due to static charge or excess heat is the unit of which we have only one.

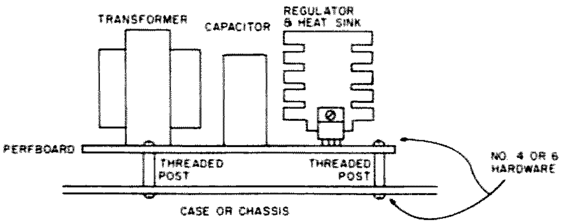

Fig 11. Mounting perfboards horizontally.

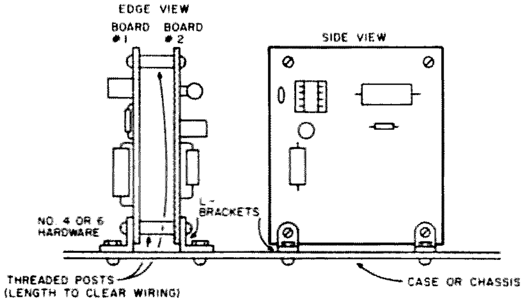

Fig. 12. Vertically mounting two perfboards.

Mounting Perfboards

The photos, besides illustrating perfboard construction generally, show different types of mounting schemes. Basically, there are only about five ways to handle the attachment of perfboards to your project case.

Fig. 10 and Photo A illustrate simple vertical board mounting using L-brackets. Digi-key and other mail sources carry this common but surprisingly hard-to-find bracket. Be sure that the board clears the case with about an eighth of an inch to spare so that you have room to align the L-brackets with the case and board holes. This is perhaps the simplest vertical mounting scheme, but it is limited by the weight and size of the project board as well as anticipated rough handling of the entire project. Vibrations transmitted to the free end of the board have considerable mechanical force.

The most common method of horizontal mounting appears in Fig. 11 and Photo B. The drawing shows mounting posts threaded for 6-32 screws. Note that in this case the transformer hardware doubles to connect to the post. The object is not to save two screws (although the space they take might be handy for other circuit components). Instead, the mounting posts support the transformer's weight directly. Had the project used comer posts, a few hard knocks might let the transformer crack the perfboard. Horizontal mounting with four-corner support is superior to L-bracket mounting only if the expanse of perfboard does not support too heavy or too dense a weight.

In most cases, hollow pillars and long screws make a perfectly acceptable substitute for threaded posts. We need not buy commercial posts, but can make our own from rigid plastic tubes. In fact, exploring the plastic packaging and worn out parts of many household items is a good way to build a stock of very useful plastic pillars, standoffs, and other items.

We can achieve superior vertical-mounting stability using two boards with a combination of L-brackets and posts. Fig. 12 and Photo C show how. Each board has its own L-brackets for four-point support. Posts connect the two boards at the four corners. With this technique, the builder can remove each board independently for repair or revision. Photo C shows separate automatic voltage- and current-measuring circuits (for a bench supply) back-to-back. The only cautions to observe with this mounting method are to ensure that the two circuits will not interact through radiation or capacitive coupling.

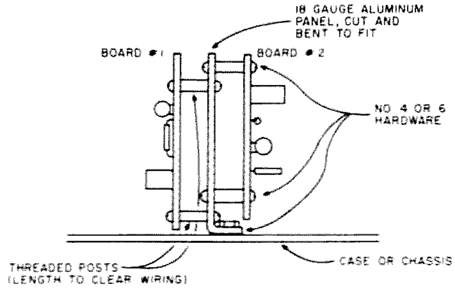

Fig. 13. Perfboard mounting with interface shielding.

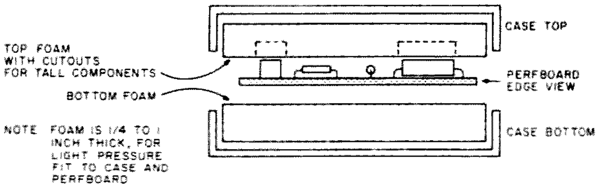

Fig. 14. Packaging perfboards in foam.

Where circuit isolation is important, Fig. 13 comes into play. Two boards conveniently fit to one aluminum shield panel. The 18-gauge or thicker aluminum panel supports both boards and the builder can remove each independently. This technique is limited to cases where a simple interface shield is adequate to prevent unwanted interaction between circuits, which includes most low-power receiving and test equipment applications.

Modern packaging techniques have taught us that rigid physical mounting is not the only route to good circuit protection in the project case. For small projects, a floating mount may be both simpler and more effective than nuts and bolts. Fig. 14 illustrates the general principle. The circuit board rides between two foam pads within the case. The case presses the foam lightly to hold it in place. The light pressure also holds the perfboard securely in its place. If there are some projecting components, we can cut a few indentations into the top foam panel. This form of mounting works very well as long as the foam can exert enough pressure to lock the perfboard in place without over-stressing any of the components.

These sample mounting methods may add to your repertoire of packaging techniques. In any event, plan your packaging during the layout stage of the project, since perfboard mounting will determine some of the cutting, drilling, and wiring requirements. Of course, these mounting techniques also apply to numerous other construction techniques.

Although perfboard is handy, it is not the ideal construction base for all projects. As noted, some rf projects may require ground planes that perfboard alone cannot provide. Where PC boards are available for projects you do not want to modify, use them. However, for the one-time ham project of moderate size, perfboard construction can be as satisfactory and durable as any other. It all depends on how you handle the material. Hopefully, the collection of ideas out of my experience will spur you to share some of your own with the rest of us who regularly build with perfboards and soldertails. ■

Watch a Warhorse Work

With a new tank circuit, the SB-221 does great things for 160 and 10.

The conversion of an amplifier to operate down on 1.8 MHz involves more than adding a coil tap and a switch position, as the 10-meter conversion usually does. A new and larger coil assembly is required, as well as a plate choke and a filament choke with larger inductance. These add up to several components and some expense. There is plenty of room in the SB-221 to place the new components, however, making the conversion a simple one. The most difficult job is removing the switch deck that shorts out the sections of the main-output π-network inductor, and then replacing it after modification.

The SB-221 as designed by Heathkit™ comes with a 10–11-meter reject filter and tuned input circuits for 80, 40, 20, and 15 meters. All being bypassed leaves the amp with an untuned input.

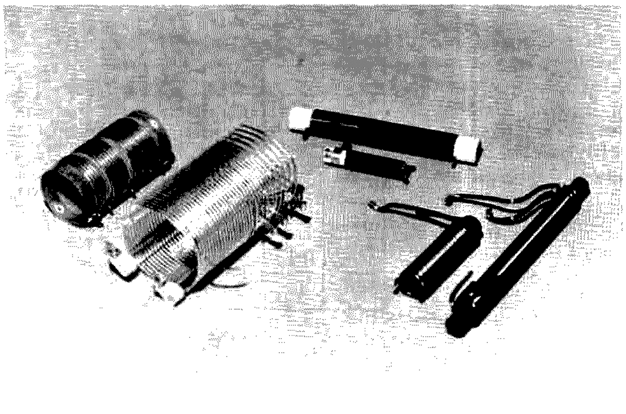

Photo A. The new components to be added to the SB-221 to convert it for 160-meter operation. The new component is the larger one in each case. The smaller original ones were removed from the amplifier.

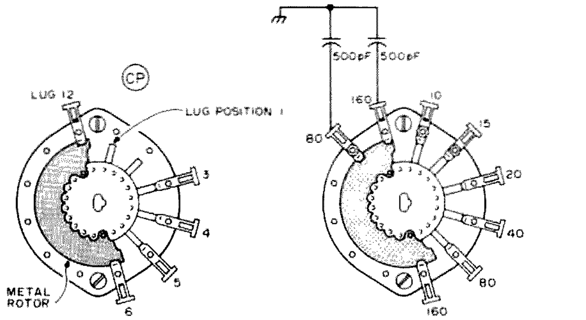

Fig. 1. The rear deck of the bandswitch as shown in the Heathkit assembly manual is at left, and the modified deck is at right. Three new switch contacts are added using new fingers or ones salvaged from old switches. They are mounted on both sides of the ceramic wafer, using #2 brass nuts and bolts. The mounting holes are already in the wafer; no modification to it is needed. The work on the switch is easy; the hardest part of the whole conversion is removing the deck and putting it back again.

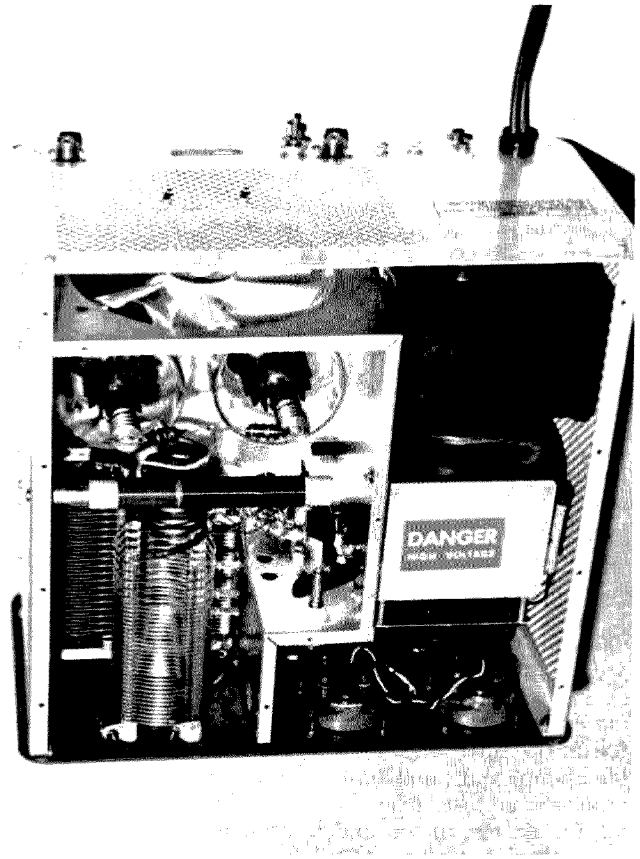

Photo B. The SB-221 converted for operation on 160 through 10 meters. The new tank coil is mounted on the front panel, using two holes that previously held a plastic Heathkit label. The new larger plate choke is mounted on the wall at left, using the original plate-choke standoff. The bandswitch is removed from the partition wall, modified, and replaced.

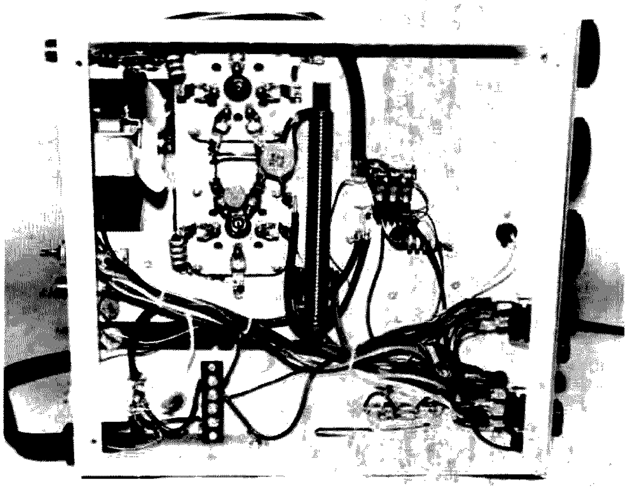

Photo C. Bottom view of the amplifier with the larger filament choke installed. It solders into the same points that the original choke did.

The new output tank coil is approximately 33 μH which uses all of the 250-pF tuning capacitance that is available to resonate at 1.8 MHz. Although a larger capacitor would give a better Q, the resulting efficiency of the amplifier is almost as good on 160 meters as on 80 meters, so that the output on 160 will not suffer from lack of a larger tuning capacitor. Additional output capacitance is also switched into the π-network to provide a 50-Ohm output on 160.

Components

Photo A shows the new components added, with each one next to the corresponding one removed from the SB-221. The new plate choke has an inductance of 200 μH rather than the 50-μH original choke. This is the Barker & Williamson Model 801. It is space-wound over about one third of its length to avoid parallel resonances at the higher frequency bands and close-wound for the rest of its length for greater inductance. The B & W filament choke, FC-25A, has about six times the inductance of the smaller Heath choke and is used to prevent the drive power from going back to the filament transformer or to ground. The plate tank coil is a B & W 195-3, a variable-pitch coil using #14 wire, 2½" in diameter, 5¼" long. It is mounted on the front panel using the two holes that originally held the Heathkit label. Cable clamps around the plastic rods of the coil support it. These are furnished with the coil.

Construction

After taking off the cover and refamiliarizing yourself with the layout, remove the 3-500 tubes. To bypass the input circuit, connect a length of RG-58 from terminal 4 of the T-R relay directly to C32 at the tube sockets. Remove the coax cables that had been connected to these points and cut them off where they pass through the chassis into the grid compartment. Ground both ends of the braid of the new piece of cable.

If the stiff wire leads on the new filament choke are bent as in Photo A, the larger choke will fit, using the same solder points as the smaller choke (see Photo B). Make sure that the filament choke is close enough to the chassis that it will clear the bottom of the case.

Remove the rf plate choke (Heath #45-61) by unsoldering both wires to it and unscrewing it from the spacer. Save this spacer to mount the new choke. Put a 6-32 nut on the long bolt sticking out from the partition to prevent it from falling loose, and cut the excess bolt off. Drill and tap one end of the 3/8"-diameter spacer for 1/4"-20 threads and put a 1/4"-20 stud into that end. This will thread into the ceramic form of the new choke. This spacer is mounted on the opposite wall of the amplifier (Photo C), using an 8-32 screw through one of the perforations in the wall.

Remove both the 80-20 coil and the 15-meter coil made from silver-plated tubing. Save this 15-meter coil; it will be used in the modified version, tapped for 10 meters. Leave the fiber standoffs that had held the old tank coil in place so that the screws holding them don't fall into the grid compartment.

Unsolder all of the wires and the capacitor from the rear deck of the bandswitch. By reaching down behind the panel with needle-nose pliers, you can bend back a tab on the outer part of the detent layer. This lets the switch rotate through 12 positions rather than the original four. Since the input circuits are no longer utilized, the back wafer that switched the coil is all that need be changed. Remove it by

loosening the bolts that hold it to the partition wall. The nuts will fall down into the grid compartment and must be recovered. Three new contacts must be added, as shown in Photo D. This is not so difficult. Many switches have similar contacts. Drill six out and mount them in the holes already present in the ceramic deck with #2 hardware. One of the new contacts is for the extra loading capacitor for 160.

The reworked switch deck is replaced, using the original hardware and spacers. Getting the nuts back on the bolts when they are almost hidden is a nasty job. Bend a piece of wire to hold the nut and get it started.

The new switch positions are shown in Photo D. No change was made to the switch labels on the front. There is no confusion, however; the 160-meter position is the one to the left of 80, and the 10-meter position is to the right of 15.

The Heathkit plastic nameplate is removed by prying off the Tinnerman nuts, leaving two holes to mount the new coil behind the front panel. Plastic cable clamps and small angle brackets are attached to the plastic ribs of the coil, as in Photo A. The 160-meter end of the tank coil is soldered to a lug attached to the front of the loading capacitor. There is room to remove the nut from the threaded rod there and put a solder lug under it. At the other end of this rod another solder lug is placed under the nut and a heavy wire run down to the 160-meter switch terminal, where the output wire running to the T-R relay also is connected.

The 7-turn 15-meter coil is connected from the tuning-capacitor top plate to meet the main coil, as in Photo C. This involves bending the tubing at the ends and cutting some from the coil. Be sure to keep the approximate size and spacing the same.

The 10-meter tap on the tubing coil is 4½ turns from the tuning-capacitor end. The 15-meter tap is now 6½ turns in, not at the junction of the two coils. The tap for 20 meters is 2¾ turns from the junction, 40 meters is 7¾ turns from the junction (5 turns from the 20-meter tap), and 80 meters is 4 turns from the 40-meter tap. These taps are made with clips furnished with the tank coil. Connections between coil and bandswitch are made with #14 solid copper wire, as in Photo C.

An additional 500-pF, 1-kV output capacitor is soldered to the bandswitch. It is placed next to the original one for the 80-meter band. The shorting rotor connects both into the output on 160, as shown in Photo D.

The tank-coil taps can be checked with a dipper before applying voltage. The tubes should be in place (but no power applied) since they will contribute to the capacity of the system and affect the 15- and 10-meter tuning. The 15- and 10-meter bands should resonate with the main tuning capacitor near minimum, beyond the shaded area marked 20–15 on the panel. Small changes can be made by stretching or compressing the turns of the coil, and larger inductance variations by changing the location of the taps.

An improperly located coil connection will show up as inefficient operation on that band. If the inductance is too large or too small, the power out will be reduced for a given amount of drive. It is worth measuring the power into a dummy load to check on efficiency, rather than just being satisified with a resonance, a dip in the plate current.

A parts kit for this conversion is offered by Barker & Williamson, 10 Canal Street, Bristol PA 19007, for $49.95. The K-160 consists of the Model 801 plate choke, FC-25A filament choke, 195-3 π-network inductor with taps and mounting clamps, and a 500-pF output capacitor. ■

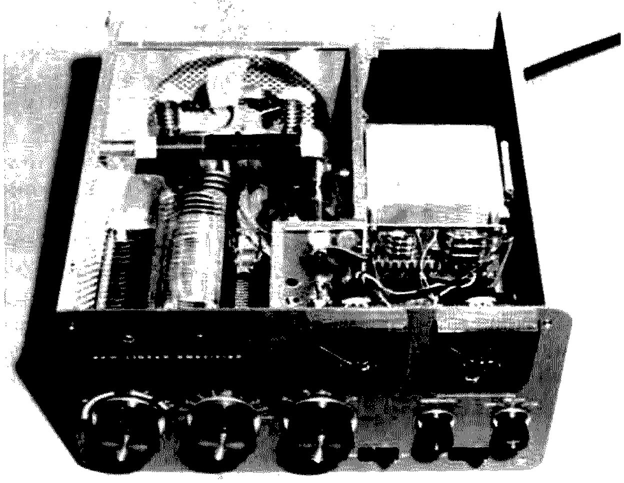

Photo D. Front top view of the modified SB-221. The two screw heads above the capacitor knobs are the only outward change in the appearance of the amplifier. The 160-meter position on the bandswitch is the one to the left of the 80-meter position; it need not be marked. Similarly, the 10-meter position is the one to the right of 15 meters.

73 INTERNATIONAL

Each month, 73 brings you ham-radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73: Amateur Radio's Technical Journal, *Pine Street, Peterborough NH 03458, USA, Attn: Perry Donham KK2Y.*

ABE VKS BAD OSLERS?

It has become noticeable lately from on-air contacts and correspondence that the VKs are getting a reputation of being bad QSLers. After looking at my log books over the years, I disagree, and feel, in fact, that the opposite is true. I will give an example later of why I feel this way.

WIA QSL Bureau

The Wireless Institute of Australia maintains both inward and outward QSL bureaus in all states, with the VK3 bureau being free of charge to all members of the Institute in VK3. (Other bureaus in Australia do charge for this service.) Nonmembers still can collect their cards free of charge from the bureau, but a fee of 10 cents per card is charged for all nonmembers' outward QSL cards. This is still a lot cheaper than by mail.

The VK3 bureau, over the last three years, has handled approximately 410,000 inward cards and 320,000 outward cards. There is a total of 30,000 cards still uncollected at the bureau, and to remedy this, Inward QSL Manager Barbara Grey VK3BYK has tried for two years to contact all of their owners. Of the very few who bothered to reply, the comment was the same: "We don't want the cards; either send them back or destroy them."

These cards have now been sorted into alphabetical order by the Ballarat Radio Club and will be filed at the WIA club rooms for a further twelve months. If not collected by then, they will be sent back to the original sender with a notation on them stating that this person does not QSL.

Our Bad Apples

For example, one VK3 two-letter callsign has been heard on air saying, "I will QSL," but this station has over 500 QSL cards uncollected in the bureau. He quite blatantly states that he doesn't want them. A case of one bad apple giving the whole box a bad name.

A recent article in one of our local radio magazines reported a request to the Federal Bureau of the WIA by a licensed member of the WIA to either destroy or send back cards sent to his XYL—also an amateur but not a member of the WIA. The intimation is that she will receive cards direct only with the appropriate green stamps or IRCs for return of cards.

While I can sympathize with her as, being a semi-rare YL DX station, her cards must be in the thousands per year and be a drain on her household budget, I can also sympathize with those countries who have amateurs on very low incomes who cannot afford to get green stamps or IRCs to send for direct QSLs and must use the cheapest method available, the bureau, to confirm a new YL country.

So I would suggest that if you receive one of your cards back marked as a non-QSLer, don't blame all of us, just contact the offending station again on air and give them a good idea of what you think of people who say they will QSL but don't; they are damaging the image of all VK amateurs by their inconsiderate actions.

The SWL

While I have no grievance against the vast majority of SWLs, I do object to receiving cards back to me via the bureau from an SWL listing a three-year-old contact with a station that perhaps lasted only one minute with "via the bureau" crossed out and a request for a card "direct to PO Box so and so." No way is a card going back direct to that station—not with the cost of direct QSLing these days.

One of the last batches of QSL cards by the bureau to me contained sixty cards. Thirty-five were SWLs of which three asked for direct QSL cards. Result: Thirty-two SWL cards went by the bureau, three went into the rubbish bin.

No Log Required

The request by an SWL for confirmation of a contact with a station is going to be even harder in future because as of late 1983, the Department of Communications granted us the privilege of not having to keep log books except in the cases of emergency situations, club stations, or when directed to do so by the DOC.

This puts us in a Catch-22 situation where if we don't log every station we work, we can receive a card from an SWL for a confirmation of a contact that we have worked, but not logged. What do we do? Enter every contact, just to satisfy the many SWL listeners? Not log them and send cards back with "Sorry, OM, not in the log," even when it was a good contact?

So, if working a VK station, this makes it more important than ever to ask for a QSL if you want a card, so that your callsign will be entered into the log book. Very few Australian amateurs object to a request for a QSL card to confirm a contact; it has been a common practice since the inception of amateur radio. However, I, for one, do not enter all my contacts. Unless a QSL is asked for during the contact, I assume a card is not required. It is only a common courtesy to ask, and, if not in the log, no card.

Who is in the wrong? Am I, for not logging you, or, you, for not asking, "Do you QSL?"

Are You at Fault?

Going by the above, we do have some problems, but some overseas amateurs requiring a QSL card also have contributed to them by not doing the right thing when sending their cards. I will mention some of the problems we are having over here with your cards.

- Incorrect callsign on the cards; for example, VK3E—. The VK3 bureau has a lot of cards addressed this way. Probably a VK2E-- was meant since no E suffix has as yet been issued in VK3.
- How do you make your "V" in VK? The bureaus are getting a lot of cards that can be either VK3 or UK3. Much time can be lost by the unpaid QSL managers trying to sort out the problem. How many of your VK cards are at PO Box 88, Moscow?
- Undecipherable scrawls or hieroglyphics for the callsign that might look great on ancient parchments make the job of the person sorting thousands of cards at a time much harder. So please print callsigns in clear, precise letters and make sure you get *your contact's* callsign *correct*. With some of our current suffixes starting with phonetically similar letters (B-C-D-E-P-V), it pays to double check.

I notice in the listing of VHF contacts by the *Columbia a* contact with VK2PMN. I don't see how that can be as the P suffix denotes a Novice operator who, as such, cannot operate above 30 MHz. Was this a typical suffix mistake that also is being reflected by cards coming into our bureau?

However, let me state here and now that VK is not the only country with QSL problems!

Only 65% Card Return

In 1978, with the 10m band wide open virtually 24 hours a day, I had great fun with a 6-element cubical quad, working all around the world at all hours of the day and night and averaging 800 contacts per month. Most of these were QSL via the bureau. Checking the logs for that year, in 1981, I was surprised at the blank spots still in the QSL-returned column. It worked out at only a 65% return of cards.

Taking the price of QSL cards into account, that worked out at a yearly loss of *around* US$200 *for non-returned cards.* Needless to say, my QSLing became more selective, to the point that now I QSL only on receipt of a card, either direct or by the bureau.

Pirates

Are you sure you are actually working a licensed amateur? The ease with which anybody can buy amateur transceivers over here, with no questions asked, is not funny. It is soon to be stopped (we hope!). With today's large sals of CB rigs able to operate in the 28-MHz band plus an abundance of articles telling you how to convert the older CB sets to 28 MHz, it would pay you to make double sure that you are indeed working a licensed amateur. We do, like a few other countries, have our pirates.

One classic example involves the genuine call of Art Cooledge VK0AC. There are over 200 cards in the bureau for a person calling himself Bob and using this call. These cards will be going back to the sender, as Bob was a pirate. There are many other cards at the bureau that are, also quite obviously, from pirate operators.

Another case in point happened last year in VK3. Direct QSL cards were arriving at the home of an SK for contacts with him months after he died. As his wife was still living at the *Callbook* address, you will understand that this was upsetting her quite a bit. As her husband had a two-letter call and these are much sought after by other amateurs, her problems were solved by issuing her *deceased* husband's call to another licensed amateur to reactivate. As this particular amateur was well known on air, anybody else using his new reissued call would be easily detected.

This change of call in VK is accomplished by a simple procedure. When an amateur becomes a silent key, his callsign cannot be reissued for a period of two years. However, if a member of his close family requires the callsign, it will either be reserved or reissued to them. If the family does not wish to keep the callsign, it is possible for another amateur to get written consent from the closest relative to the deceased to take up his old callsign before the two-year period expires.

This gives you another problem with QSLing, as, in the above case, it is possible to have two owners of the same callsign only a few months apart.

So, if the station you are working says his QTH is near Melbourne, for instance, ask him his exact location, then look in a late *Callbook* to confirm his name and location before sending off that QSL card. I reiterate: Use a *late Callbook* because a lot of the two- and three-letter callsigns have been reissued over the last few years.

Direct QSLing

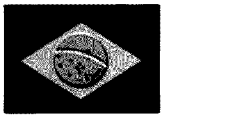
Speaking of direct QSLing, *although* Australia is called "The Lucky Country," not all of us are millionaires. You will find the usual cross section of the population involved in amateur radio, including students, pensioners, handicapped operators living on an invalid's pension, young marrieds with the usual mortgages and rearing children, etc. All of these people face the

common problem: The cost of QSL cards can be a noticeable drain on meager finances. Add to this the practice of some overseas operators who send unexpected cards direct airmail with no return postage included and request a card back the same way, which happens quite often, and we can be in a dilemma as to what to do. A letter to Europe airmail is A$.85 plus card and envelope. It works out at around US$1.00 per letter, and it is not much cheaper sending it by surface mail. One week I had five ot these letters.

Do I pay US$5.00 out of my own pocket just to confirm contacts with a country they have probably worked many times before? Do I instead send the card back by the bureau, knowing it might take two years to reach them or that they may never get their card if they are not a member of their local bureau? The result of the latter could be more overseas amateurs saying that the VKs are lousy QSLers.

While this is not the full story of QSL problems, I hope it will partly explain that it is not all our fault and that where we are at fault we are trying to remedy the situation as quickly as possible.

The rest is up to you.



BRAZIL

Carlos Vianna Carneiro PY1CC

20270 Rio de Janeiro, RJ
Brazil

Ivete Alvos Monaco PY2ADI
Grupo de CW de Sao Paulo
Caixa Postal 15,098
01000 Sao Paulo, SP
Brazil

As Public Relations Chairman for Grupo CWSP, I would like to announce two awards.

Our CWSP Award is for all amateurs who have worked five members of our group (CW only) with valid contacts after October 15, 1978. Submit a list certified by an official radio club, with suffixes in alphabetical order, date, band, and report. (SWLs same rules.) Do not send cards. Fee, 10 IRCs. For endorsements (one for each ten PY2s up through 80), send one IRC and an SAE.

CWSP members are PY1DG and PY2s AC, ACH, ADI, AES, APE, ARX, ASI, ATL, BTR, BWD, BZD, CAR, CJW, CMS, CPU, CZX, DCP, DHP, DML, DRP, DY, EGM, EMM, FEO, FT, FWR, FWT, GCW, GPA, IAP, ICN, IEJ, JN, OE, RAN, RVO, SI, SPA, SUB, SV, SZA, TO, TR, TRD, TUO, UZV, WG, WR, and XB.

The Brazil CW Award (BRCW) is issued by us for any radio-amateur stations working at least 15 different Brazilian states and territories from Brazil, *which stations already have earned all 6 endorsements for the CWSP Award.*

de PY2ADI

BRAZILIAN PPC MEMBERS AND COUNTRIES AWARD

As a special celebration during PPC's 20th year (March, 1984 to March, 1985), this oldest Brazilian CW group has just announced the PPCMC Award (CW mode only). It's a tribute to radio amateurs of all parts and to those who give their best towards CW development. The PPCMC Award combines all countries (ARRL list) and PPC members. QSOs must have been made on and after January 1, 1980.

Issued by the Brazilian Picapau Carioca Group, this award is available to all radio amateurs as a permanent competition.

Each ARRL country and each PPC member counts 1 point, only once, no matter which band, two-way QSO.

Basic Award—Two-way QSOs completing 50 points, involving at least 40 different countries.

Endorsements—Two endorsements, 25 points each, until 100 points; from 100 points to 150 points, 5 endorsements, 10 points each; from 150 points on, endorsements at any requested quantity, at will.

Honor Roll—Those reaching 200 points.

No QSLs needed. Send list (GCR) in suffix alphabetical order showing full details of QSL, verified and certified by a recognized amateur-radio society. Fee for the basic award is 5 IRCs accompanying applicant's QSL card with complete QTH information. For endorsements, send SAE and 1 IRC. Address PPC Certificate Manager, PO Box 2673, 20001 Rio de Janeiro RJ, Brazil.

WORLD'S HIGHEST 2M REPEATER

For those of you who read our article in the June, 1983, issue of *73*, it may be of interest to know that the 2-meter repeater installed on the top of El Plomo mountain at 5,500 meters above sea level worked perfectly for about 4 months until the antenna broke down due to the heavy winter winds. Nevertheless, the repeater system continued to work (although the signal was extremely low) during all the winter season, and the repeater and solar panels suffered no damage.

Last summer, a group of hams climbed again to the top and repaired the antenna damage, replacing the old antenna with a very light and flexible whip which we hope will survive the coming winters.

By the way, we would like to hear from other hams around the world, just to know if our repeater is still the highest.

WACE AWARD

Radio Club de Chile continues to issue its WACE Award to all hams who send proof of contacts with each of the 10 Chilean zones. More details and information can be obtained by writing directly to: Awards Manager, Radio Club de Chile, Casilla 13630, Santiago de Chile.

RECIPROCAL LICENSING

During our summer months especially, many hams from various parts of the world visit Chile and make use of our reciprocal license agreements. In fact, Chile has official agreements with the following countries: Argentina, Brazil, Canada, Colombia, Ecuador, Israel, Uruguay, and the USA. Nonofficial but equally good treatment has also been given to hams from the Federal Republic of Germany, England, Panama, Spain, and Japan.

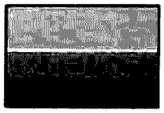
Chile is known for its skiing facilities during our winter months and for its trout fishing during summer on its many lakes and rivers south of Santiago.

During the past summer season, we enjoyed the visits, among others, of DK2BI, DK9WB, and DK6HH, who were here during early March, and also Lloyd and Iris Colvin of world fame, who at the time this is being written are still enjoying lobsters and DXing on Juan Fernandez Island. They also visited Easter Island for about 2 weeks and were able to make over 8,000 contacts during their stay on the island of the mysterious Mohais. We are sure that they will always remember their visit to CE land.

Patricio CE3GN (far right) and his wife, Ana Maria (center), with Lloyd and Iris Colvin, enjoying a barbeque at Patricio's QTH just before leaving for CE0Z.

COLUMBIA

Much has been written about Dr. Owen Garriott's flight and contacts from *Columbia*. Nevertheless, we would like to repeat the fact that only 2 South Americans were able to make it. The nice thing about it is that both of them are Chileans! Our congratulations go to Andres CE2AHD and Ignacio CE3CKE, who appeared on the official list of contacts.



COLOMBIA

Abelardo (Lalo) Santos V. HK3EOU
PO Box 88937
Bogota 8
Colombia

COLOMBIAN INDEPENDENCE CONTEST

The Colombian Radio Amateur League (LCRA), founded in 1933, will sponsor the CID 1984 Contest, running from Saturday, July 21, at 0000 GMT till Sunday, July 22, at 2300 GMT.

The Colombian Independence CW and Voice Contest will include the A category: single operator/single band, voice only, CW only, or mixed; B category: single operator/multi-band, either voice or CW only or mixed; C category: multi-operator but with single station, multi-band voice, CW only, or mixed operation; and the D category: multi-operator, multi-transmitter, multi-band, either voice or CW only or mixed.

There is also a single-band category for operators using 14 MHz against those operating on 7 MHz, etc. The bands of operation will be 1.8, 3.5, 7, 14, 21, and 28 MHz. The contest call will be, for voice, "CQ HK CONTEST," and for CW, "CQ HK TEST."

The QSO exchange for non-HK stations for voice will be composed of the signal report followed by three (3) digits starting from 001. For CW, the exchange is the RST report plus three (3) digits beginning with 001 as in the voice modality.

For HK stations, there will be a special procedure which includes the signal report, the number 174 (indicating the 174th Colombian independence anniversary celebration), and the QSO sequential number. The same will apply to the CW QSOs, namely, RST, the number 174, and the QSO number.

The scoring for non-HK stations will be: for working HK contest stations, five (5) points, working non-HK stations which are outside their own country, three (3) points, and working stations of their own countries, one (1) point.

For HK stations, working non-HK stations earns five (5) points and working other HK stations earns three (3) points only. For the combination of different countries contacted on each band as well as QSOs with different HK districts (there are 10) worked on each band, the usual multipliers will apply.

The total number of QSOs multiplied by the total of countries contacted and the different HK zones contacted in the different bands will give the definite numbers, the final score.

The log entries should include the time in UTC, callsign of station worked, report given, report received, multiplier, and the points corresponding to the QSO. Separate log sheets should be used for each band.

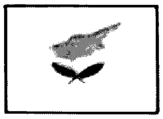
The multipliers should be indicated/applied only for the first QSO on each band. Finally, a summary sheet must be attached to each entry indicating the total points, category, name and address, list of operators in the case of multi-operator stations (if applicable), plus the usual contest declaration. The submissions not including a summary sheet will be considered only as check logs.

Sole conditions of entry for participation are that each participant should communicate with at least ten (10) HK stations on voice or five (5) HK stations on CW for acceptance by the Contest Committee and must submit written proof of a total of fifty (50) QSOs, ten (10) of them with HK stations on voice or five (5) on CW to qualify for any prize. Should the contester wish to work in the mixed category, he will need to contact only five (5) voice and five (5) CW HK stations. One contact per band with the same station is acceptable; cross-band or cross-mode QSOs are not valid.

Violation of the amateur-radio international as well as country's regulations or the contest rules, the lack of ethics, so-called "phantom QSOs," excessive duplications in the total number of QSOs—all will be reasons for disqualification by the

LCRA Executive Committee, and their decision will not be subject to appeal.

Logs should be mailed by August 30, 1984. Those received after December 30, 1984, will not be considered but will be gladly used as check logs. The entries must be addressed to: LCRA, Contests, Logs and Awards Department, PO Box 584, Bogota, Colombia, South America.



CYPRUS

Aris Kaponides 5B4JE
PO Box 1723
Limassol
Cyprus

NEWS FROM CYPRUS

On March 10, 1984, the Cyprus Amateur Radio Society (CARS) held its annual general meeting and a new central committee was elected: Totoe Theodossiou 5B4AP, President; Aris Kaponides 5B4JE, General Secretary, and Pantelis Lytridas 5B4CF, General Treasurer. Members are Thanos Apostolides 5B4CR, Christoforos Demetriou 5B4EI, Sotoe Miltiadou 5B4JX, Andreas Pavlides 5B3AC, George Kourtellis 5B4DY (Nicosia), Stelios Ioannou 5B4AH (Famagusta), Nicos Hadjimiltis 5B4CV (Limassol), Andreas Christoforou 5B4JR (Paphos), Erricos Lanitis 5B4GJ (Larnaca), Glafkos Kariolou 5B4MM (Kyrenia).

A new UHF repeater was bought by CARS and soon it will be operational. At the moment it is being tested by the repeater technical manager, 5B4AH, and then a suitable site will be found.

Cyprus was represented in the CQ WPX Contest by four stations: 5B4MF, 5B4ES, 5B4LP, and 5B4EP.

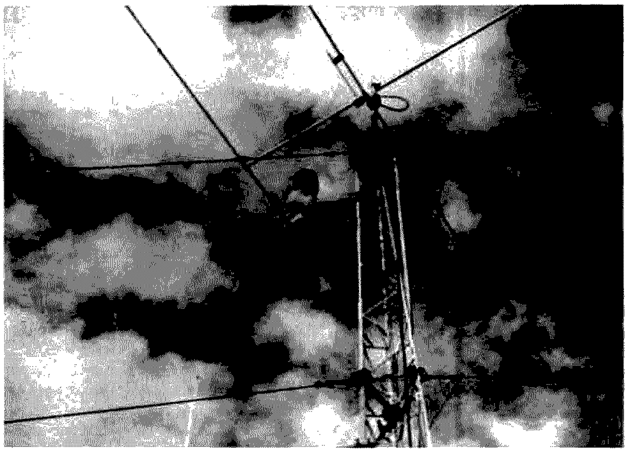
OM Andreas 5B4LP operated solely on 80m, and he claims that he has broken the continental record on this band. OM Marcos 5B4EP operated on 160m only with good results also. 5B4ES (the Nicosia English School club station) operated multi-operator/multi-band under the guidance of Dr. Larry Day 5B4LD.

During the last couple of months, the regular 5B4 DXers operated on all the HF bands. 5B4EP, during the mornings, was on 160m. On 80m, 5B4LP, 5B4MD, and 5B4JE were showing up most evenings, and on 40m, 5B4JE was working with a new delta loop antenna with the company of Roberto I2VRN (the strongest signal on this band from Europe). Also, several 5B4s were operating on 20m, 15m, and 10m. On the 10m FM mode, regular operators were 5B4MD, 5B4LP, 5B4MF, and 5B4JE.

Being a very small country with a handful of amateurs active on the bands, it is difficult to find news for publication, so I am going to describe some interesting amateurs on the island. Here is a short portrait of OM Nicos Hadjimiltis 5B4CV, who is also a neighbor and a very good friend of mine.

Nicos got his ticket in 1976; he is an engineer with a broadcasting station, specializing in antenna construction and erection.

Nicos 5B4CV (left) with visiting friend DF3MG.



5B4CV doing some antenna work.

Nicos has been operating regularly on all bands and modes. He is a great home constructor, and among his constructions are an HF linear, a couple of antenna tuners (one of which is remotely controlled), power supplies, a TV camera, and other gadgets. His latest project is a Robot 400 converter for SSTV.

His is the only station in Cyprus operating now on RTTY and SSTV. Nicos is also the president of the Limassol CARS group and is one of the main helpers in running the Limassol club station; he always is prompt to help fellow amateurs.

Radio amateurs here, as of July, are licensed to work 1.8 and 10.1 MHz. On 1.8 MHz are those licensed for 15 W input maximum. 160 meters is divided by mode: CW on 1.81–1.90 MHz, and CW and SSB on 1.90–1.95 MHz. On 10.1 MHz are amateurs licensed to work CW and RTTY, with RTTY on the last 10 MHz of the band. As of January, 1985, 18.1 and 24.9 MHz will open.

Journal Funkamateur (number 7/1983) brought information about the USSR. In 33 thousand club stations are half a million having an interest in an amateur activity, with 2150 champions active on internal USSR QSOs and 58 champions active on international QSOs.

Number 8/1983 *Journal* reported results of the first SNERA competition in the USSR. (SNERA contributes to scientific perceptions of polar radiances and their influence on UHF.) The winner was UA3MBJ with 1716 points; second was UR2ROT with 1616 points; UR2RIW had 1239 points. The best club station was UK9CAM with 365 points, and one SWL, UA3-142-198, had 221 points.

Every year, at least one world record in the 10 GHz band is the aim of Nicola I9SNY, Perrugia, Italy. Last year, in July, Nicola was in the Ceuta (EA9) and was reached as callsign I9SNY/EA9, in location XV04c, by station IW0BCU/IT9, Sicily, in location GY84c, a distance of 1621 kilometers, for a world record in the 10-GHz band. Nicola repeated his contact with station I9NLK/IT9 of that same location. On the same day, three hours later at 1912 UTC, Nicola surmounted that world record by contacting station Pietro I0YLI/IE9 on Ustica Island (north of Sicily), location GY28b, a distance of 1863 kilometers.

Nicola also reached a new European record on 1296 MHz with his contact with station I8TUS/8. Operator Salvatore was worked in south Italy at location IZ41n. The distance was 1914 kilometers, beating the old European record of 1577 kilometers between OK2BFH/P and G3AUS on October 30, 1982.

Thanks for information and letters from W2HAE, W4NBZ, and WA0HWH, but I cannot send back letters—I am very QRL.

de RK, OK3KFO

MARCH, 1984

Traditionally, the month of March is devoted to the activities of YL operators in OK. This is in connection with the International Day of Women, March 8, celebrated in OK as well as in all socialist countries.

The March issue of *Amaterske Radio* (usually designated as AR) brings the story of the first YL operator in Czechoslovakia. She was Jarmila Hermanova from Talc in Moravia, and during the period 1929 to 1931, she worked under the callsign OK2AJ. The first Moravian hams, OK2AG and OK2AC, initiated her into amateur radio.

Daughter of the director of a local power plant, she was successful at the exam in 1931 and was offered a bouquet of roses by the president of the examination commission (Ministry of P and T), Dr. Burda. In 1933, her callsign was changed to OK1YL. Her equipment was confiscated on March 18, 1939, during the Nazi occupation. She passed away in 1971, in Zirovnice.

The *Radio Amateur's Messenger* for February, 1984, brings more news concerning YL operators. In fact, since the end of 1983, Jozina Zahoutova OK1FDL has been the president of the Central Radio Club. Her husband and their two children are also active hams. They live in Pribram. Let me here send best wishes of peace and happiness to all YL ops from OK land, where we have grown from one YL in 1929 to over 150 today.

PO Box 2191
Santo Domingo
Dominican Republic

THE TWINS AGAIN

Radio Club Dominicano has just elected a new directing board headed by Cesar Dessangles HI8CQ, twin brother of Ernesto HI8CW (former RCD president in 1977). They are the sons of Roberto Dessangles HI8RD who was himself president in 1976.

The great work done by the twins in 1976 helping their father, and then in 1977 during Ernesto's presidency, makes us anticipate a successful performance in 1984.

The advantage of the twins, when either one of them occupies the presidency, is that RCD really has two presidents in one, sharing the work and keeping the club and its membership constantly progressive.

Anyone who doesn't know them well will find it difficult to tell one from the other—and there you can be talking to the wrong one, who's not the president, to deal with some club subject, but it doesn't matter . . . since either will do. Nevertheless, if you want to make sure, just lift up his shirt and you'll find on Cesar's abdomen a scar that Ernesto doesn't have.

The twins are popular in Dominican ham radio, and when they stay away from radio equipment, it's just due to their professional work as architect-engineers which occasionally takes them to other cities around the island.

Just as in 1976–77 the Dessangles' directing board developed a team working plan that was remarkable, a replay is now expected, with the help of the other members of the board and of all the membership in Radio Club Dominicano, Inc.—the most prestigious institution of Dominican Republic ham radio.

Other board members are Eduardo Hued HI8EJH, vice-president; Charlie Catheline HI8CCB, secretary; Tony Lake HI8GAL, treasurer; and Waldo Pons HI8WPC, Wil-

From left to right: Cesar HI8CQ, Tim HI8MFP, and Ernesto HI8CW.

liam Read HI8WRE, Frank Caraballo HI8FCN, Osvaldo Castillo HI8OCB, and Winston Vargas HI8KW.

Immediate plans are for the contests of the Republic Restoration and the Radio Club Dominicano Anniversary. Dates will be given in the near future, as well as information on CW classes and equipment operation procedures for new ham-radio operators.

The twins and the board would like to set up new antennas for the club, organize a work laboratory, and, of course, as a well-established tradition, organize the popular DXpeditions to Saona Island in zone HI2, which always gives rise to much activity and great fun.

I want to thank our readers for all the letters and notes on the *73* international section. I have answered them personally, trying to help them out.

Soon I hope to have an interesting column about the important reasons why HI QSLs are either not getting here on time or just don't get here at all!

QCWA IN DL

In April, 1983, the managing board of the Quarter Century Wireless Association (QCWA) elected Jean Wolff LX1JW to be a member of the Hall of Fame. Jean is the fourth QCWA member and the first European to be thus honored. One has to consider that only one member out of 10,000 QCWAers is chosen per year. For the German chapter and all the radio amateurs in Europe, a very good success.

Together with OOTC, SOWP, and the promoting association, "Foerderverein Amateurfunkmuseum e.V." (Society for Promotion of an Amateur-Radio Museum), we managed a stand at the "Ham Radio 1983" (largest national amateur-radio fair) in Friedrichshafen/Bodensee. Many visitors showed great interest in our stand and did quite a lot of eyeball QSOs. Saturday night, our meeting took place in the administration building. We met again a week later, June 24, 1983, in Waldrach, in the area of Trier, and on Sunday we had an enjoyable trip to Luxembourg, including a sightseeing tour, LX1JW being our tour guide.

After the sightseeing, we drank a bit of champagne with LX1JW in his QTH—about 100 people were participating in this "small" party. We were very interested in the station equipment and admired the 21 antennas. After having a nice lunch and after a visit to a wine coop, we took a beautiful trip on a steamship on the Moselle under excellent weather conditions. We returned to Waldrach and spent the evening with interesting conversations.

Our guests from the USA were: Charles W4SVB with his XYL Peg, Bill KD4ZY with his XYL from Chapter 107, Gene W5EJT, with his XYL Ruth, and K5OPT from Chapter 37. W4SVB presented to the German chapter a nice plaque from Chapter 107. After a sightseeing tour to Trier the next day, we returned to our homes.

On September 6, 1983, about 25 amateurs and their XYLs met at the QTH of DL7AC. LX1JW was honored to receive a plaque from W5KL, vice-president of QCWA. The event was recorded by the broadcast station, "Deutschlandfunk." Later we did QSY to a restaurant, where we spent the whole night.

When the vote to the QCWA board in the USA took place, DL3ME was reelected as director. Out of 15 directors, he was voted into the 4th position. The votes in the German chapter are also finished. The previous managing board was confirmed. The German chapter now starts its seventh year.

70-CM MOONBOUNCE (EME)

On June 13, 1964, just 20 years ago, a group of radio amateurs around HB9RG happened to do the very first 70-cm transatlantic QSO with KP4. The 1000-foot parabolic reflector, gain at 70-cm, 50 dB, which was used by KP4BPZ, had led to this spectacular success. The group (DL9GU, DL3NQ, DJ4AU, DJ3EN) utilized "only" 500 Watts rf, a 5m dish, and an rx with tubes (7 dB). The signals: gain up to 15 dB signal-to-noise ratio. For the group this surely was a great success.

One year later, on July 3, 1965, DJ4AU with his 80-element group antenna, rx input with EC88 and 4CX250 PA—was capable of exchanging 559 reports via the moon with KP4BPZ. Also the first SSB QSOs were worked. Such well-known calls as DL3YBA (4 x 22-element yagis) participated in this action.

On July 24, 1965, KP4BPZ was worked again in CW and SSB by DL stations DL6IQ and DL1EI. Here the equipment was relatively simple also—a 36-element group, rx input with 416B and "only" 200 Watts rf.

Some years have passed now, and with better receivers (GaAsFET) it has become quite a lot easier working EME successfully on 432 MHz. Nowadays, almost 20 radio amateurs in DL are active in this mode. In 1983, the opportunity existed for almost everybody to work via moonbounce.

Radio astronomy was "born" back in 1933, on April 27. Working with international radio communications, Karl Jansky (1905-1950) found a disturbing noise received by the experimental antenna. Jansky came to the conclusion that this noise came from space. The radio emissions of our Milky Way system were discovered. In memory of Janksy, the president of AMSAT-USA, W3IMI, and K8HUH put into operation an antenna of the Greenbank Radio Telescope on 432-MHz EME. After a short echo test, the first station was reached on May 13, 1983—DJ9DL in CW with a 559 report at 1910 UTC. This was followed by DF7VX at 1950 UTC, also with 559 on both sides.

For Europe the moon now set, and the next QSO in DL took place on May 14. Jan DL9KR exchanged 57 in SSB with K8HUH at 1202 UTC. Then the QSOs increased rapidly: 1240—DJ8QL 559/579 in CW, 1300—DF9CY 449/449, 1334—DF3RU 559/579, 1344—DF9AS 55/56 in SSB, 1347—DJ5VI 55/57, 1355—DL6NAA 55/55, 1506—DC9RH 44/44, 1653—DJ6MB 559/559 in CW, 1658—DF7KB 559/559 (his very first EME QSO), 1920—DL1BP 43/53 in SSB, 2017—DJ7YP R0/R0. On May 15, DF9CY started at 1330 with 449/559, DL6WU at 1432 with 449/469, and DL9KR made an SSB demonstration for visitors at K8HUH around 1450. Then, 1616—DK5AI 549/559 in CW, 1710—DK1PZ 449/449, 1723—DL2CJ 449/449, 2037—DK3YC 339/419, 2109—DF3EE 549/419, and for the last DL station, DJ9BV 239/R0.

In this list some well-known calls are missing, but on the other side, some amateurs worked their first EME QSO with relatively simple equipment. DF3EE: only 4 antennas and 250 Watts, DJ7UP: a 21-element Tonna and 400 Watts rf, and JA0CC: 4 antennas and only 40 Watts.

It was suggested that the information about the NRAO-K8HUH 432 EME test was received only by insiders. Otherwise, certainly much more activity would have taken place. The station equipment of K8HUH, a mirror of the interferometer with a diameter of 43 meters and a wideband cross dipole (250-500 MHz) in the focus of the mirror, was used for antennas. The focus is located 18m away from the mirror itself. Also, the 150-Watt transistorized PA and the GaAsFET preamplifier are installed here; these were controlled by different sets, such as MM432/28, IC451, IC720, or Drake R4B. Their own echoes had been heard 59.

In the time period of May 13 to 16, 1983, 132 different stations were worked in 250 QSOs. One time Africa, 6 times Asia, 67 times Europe, 54 times North America, 1 time South America, and 3 times Oceania. Besides, the "WAC 432 MHz" could be worked during these 35 hours.

OJ0MA IN RTTY

Market Reef was QRV in RTTY for several days in June, 1983. OP Kee OH0NA reported: Maerkets Fyr (Market Reef) is situated in the Baltic Sea between Sweden and the Aland Islands. The reef measures about 85 by 310 meters and is about 3 meters above sea level. Three "cottages" were placed on the bare rock: a depository for wood and oil, another for engines and tanks for oil and gas, and finally a small house with six rooms and a kitchen.

That year (1983) the station consisted of a Drake TR-7/RV-7, an Alpha 374, and a "Telereader." Antennas used: a TH3MK3 for 20 meters on a 15m-high, solid-concrete mast, a 2-element beam for 40m, dipoles for 80 and 160m, and a GPA for 40/20/15 and 10 meters.

Some hints now for ops and visitors to Market Reef: Every licensed visitor can get a transmitting permission if the "Alands Lotsfoerdelning" (pilotage service) agrees with the tour to Market Reef. This agreement includes the providing of food. It's only a 25-kilometer trip between Aland and the Reef, but sometimes it's very hard to land on the rocky coast. Last year we had to wait 4 days to come through; this time it was OK the first day. If you want further information, please contact Karl-Erik Eriksson, SF-22430 Saltvik, Finland. That's the QSL address, too.

de DJ8BT

ATOMIC CLOCKS

Can you think of a moderately-priced clock in your ham shack which shows local time accurate to 1 ms, date and day of the week, and which automatically adapts to the changes of summer/winter time and leap years? Which synchronizes itself within 2 minutes after a power break? And which has a long-term stability of 1 second in 300,000 years?

This is no dream for German radio amateurs anymore since a whole range of appropriate clocks is on the market. Prices range from 300-400 DM (115-150 US dollars) for complete units. Examples are the Renkforce atomic-clock system ACS-77, the DCF77 atomic clock made by Schwille-Elektronik (PO Box 801609, 8000 Muenchen 80), and the Hopf atomic clock 4300 (distributed by Conrad Elektronik, PO Box 1180, 8452 Hirschau).

In addition, the radio amateur can take advantage of another feature of these clocks. All of them have a receiver which picks up the required time signals on a frequency of 77.5 kHz. This transmission is controlled by the Physikalisch Technische Bundesanstalt in Braunschweig, Germany, which is an institution comparable to the National Bureau of Standards in other countries. The emission on 77.5 kHz has a frequency stability of 0.001 ppm within a period of 10 seconds and a much higher stability on the order of 0.000001 ppm for extended periods of time.

It is relatively easy to synchronize a 10-MHz crystal oscillator with this 77.5-kHz signal. Tests have shown that by this technique, a low-cost 10-MHz reference frequency signal can be generated with an accuracy of at least 0.001 ppm. It can be used as a solid basis for accurate frequency synthesizers, for frequency dividers to be used for transceiver calibration, for the synchronization of the crystal oscillator in frequency counters to improve their accuracy and long-term stability, and for numerous other applications. (Construction articles for the DCF77-controlled clock appeared in Reference 1 below and for a DCF77-controlled 10-MHz frequency standard in Reference 2.)

All these features are made possible by a special service of the PTB. According to the definition that 1 second equals 9,192,631,770 periods of a specific radiation of the nucleons of 133Cs, PTB utilizes this standard in its atomic clock CS1, which generates highly accurate time and frequency signals. The time signals are encoded and transmitted by station DCF77 near Frankfurt/Main on 77.5 kHz. Both the time signals and the transmitter frequency are controlled by CS1. The transmission of

DCF77 can be heard in an area of about 600 kilometers around Frankfurt/Main, i.e., in most parts of Germany.

The signals of DCF77 can be picked up by a simple loop or ferrite antenna. After filtering and amplification, they are decoded to obtain the date and time information which can be displayed. Furthermore, the carrier of DCF77 can be amplified and utilized directly to synchronize other signal generators as discussed earlier. If DCF77 cannot be heard, a very similar but more commonly-available technique to produce precise reference signals on the basis of AM broadcast transmissions is described in Reference 3.

The German radio amateurs are only a small but nevertheless grateful portion of all consumers of the DCF77 time and frequency signals. In the meantime, PTB controls by means of DCF77 the clocks and transmission frequencies of broadcast and TV stations, the time announcements on the telephone, the clocks of railway stations, and meteorological services, to name a few. Altogether, the atomic clock and the time and frequency signals derived from it play an important but often unnoticed role in the lives of almost everyone here. For ham radio, however, I think it is a particular challenge to make even better use of it in the future.

de DJ3NW

FINLAND

Radiomatoorikerho Kuopion Seitoset ry
Box 142
70101 Kuopio 10
Finland

Location NW19 H, Kuopio—not exactly in the middle of the world but almost in the middle of Finland—is the spot where the 25th summer happening of the Finnish Radio Amateurs Association, HAMSSI 84, will take place July 19–22, 1984. The happening will be organized by Kuopion Seitoset, the local club for radio amateurs—which will be 30 years old this year.

HAMSSI 84 will be a happening for the whole family, and the organizers are expecting participants from several countries. The program consists of, among other things, the Nordic Championship of radio orientation, pileup contest, a photograph exhibition which is composed of the harvest of a contest on the subject "Radio Amateurs," lectures on various subjects such as "Satellites and Radio Amateurs," DX dinner, YL meeting, old-timers meeting, and the biggest flea market in Finland. The members of the family have also been taken into consideration by arranging a cruise by ship, city sight-seeing tours, and, especially for children, there are puppet shows, pony riding, games, and playing. A detailed program will be sent when requested.

The event will take place in Rauhalahti, an area which is situated only 5 km to the south of the center of Kuopio. In the area there is a new modern camping site with beaches and saunas on the shore of Lake Kallavesi, a high-class hotel, and a group of buildings belonging to a mansion which will serve as the center of the whole summer event.

The town of Kuopio is situated in the largest lake district of Europe. There are 76,000 inhabitants in the town, which is the center of tourism, administration, and culture for the whole eastern part of Finland. There are lots of things to see and experience in Kuopio. The beating heart of Kuopio is the marketplace—a lively meeting place of international tourism. There are five interesting museums in the town; the Finnish Orthodox Church Museum is the only one of its kind in western Europe. There are eleven hotels, two summer hotels, and two youth hostels in Kuopio. The town also is the center of Finnish inlake boat traffic: There are eight passenger ships departing from the harbor of Kuopio daily. Everyone surely can find something to his taste!

Radio amateurs throughout the world now have, within the framework of their hobby, an excellent opportunity to come to Finland to take part in an international camp. It is organized in the middle of summer when Finnish nature is at its best: The sun hardly sets during the nighttime, the district is, to a great extent, uninhabited, the tens of thousands of lakes inveigle you into cruising, and the green forests invite you to rove on paths. You have an excellent opportunity to get yourself acquainted with this beautiful Scandinavian country, its capital, Helsinki, and the hills of Lapland to the north of the Arctic circle, before or after the camp.

The boat and flight connections from Europe to Finland are good. Those participants who are coming from further away are advised to collect small groups and make use of the advantageous group prices of the airway companies. Contact your own club in order to be able to come to Kuopio. There is room at the camping site, but it is wise to make all other reservations for accommodation, as well as the reservations for flights and ships, in good time.

Hamconvention topics and activities will include Operating VHF/UHF in Modern Environments, Towards Gigahertz, Antennas, DX Operations Today, a Contest Forum, SSTV/ATV/RTTY, the DX Dinner, Nordic and Finnish Championship in Foxhunting and YOU too, CW competition: Amateurs against Defense Forces, Police, and Association of Finnish Radio Telegraphists, Electric Security in Ham Radio, New Technology used in Ham-Radio Equipment, and Amateurs and the Microcomputer.

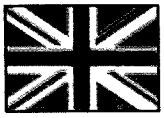
We have a foreign-visitor manager who will be very glad to help and guide you during your visit to HAMSSI 84, and main topics will be interpreted in English.

Kuopio is about 450 km northeast of Helsinki with good rail, road, and air connections. Accommodations can be arranged at the first-class Rauhalahti hotel or the campsite nearby. The Rauhalahti campsite is situated about 5 km from the center of the town. It is modern and well equipped: cafe, kiosk, beach, 4 saunas, rowing boats, modern shower and washrooms, and parking areas for cars and caravans.

Campsite reservation: Kuopio Tourist Service, Haapaniemenkatu 17, SF 70100 Kuopio, Finland, Tel. +358-71-114101, Telex 42163 ktour sf.

Hotel reservation (preferably before May 30, 1984): Hotel Rauhalahti, Katiskaniementie 2, SF 70700 Kuopio, Finland, Tel. +358-71-311700, Telex 42242 rauha sf.

Further information: Mr. Joxa Hartikainen, OH 7 00, Kauppakatu 45, SF 70100 Kuopio, Finland, Tel. +358-71-124311, Telex 42138 carls sf.



GREAT BRITAIN

Jeff Maynard G4EJA
10 Churchfields
Widnes WA8 9RP
Cheshire
England

One of the most rewarding spin-offs from writing a column such as this is the receipt of letters and cards from readers. Since writing for *73*, I have received all sorts of requests and snippets of information not only from readers in the United States, but also from Africa, Asia, and Australia. Usually I try to put together a personal reply and write directly to the correspondent. A recent QSL card, however, prompted me to put together this particular column.

Ron Johnson WA5RON of Silver Creek, Texas, wrote asking for information about our 4-meter (70-MHz) allocation. I had not previously used this as a topic because I did not think anyone would be interested in a VHF band to which they did not have access. Ron's letter, though, suggested that US hams would find details of 4 meters of interest and he asked a number of pertinent questions.

The 4-meter band is spelled out in the UK license as follows. The band coverage is 70.025–70.5 MHz with usage being on a secondary basis (some military systems use 70 MHz and have priority at all times). The maximum allowable power is 50 Watts dc input (or, in Department of Trade and Industry terminology, "133.33 Watts Radio Frequency Peak Envelope Power").

Allowable modes on 4 meters are AM (including CW, of course), SSB, and FM. Although 70 MHz is classed as a VHF band, only class A license holders have access. VHF-only class B licensees (i.e., those who have not passed a code test) cannot use any band below 144 MHz. Needless to say, this restriction is viewed by some as rather pointless—its major impact is to reduce the number of potential users of the band.

As with all VHF bands in IARU Region One (Europe and Africa), there is a band plan for use of 4 meters (like the others, it is a voluntary plan but, nevertheless, is mostly adhered to). The plan seeks to separate the non-compatible modes (i.e., SSB and FM) whilst giving everyone a fair share of the available spectrum.

The 4-meter band plan is as follows:
70.025—Beacons only
70.075—CW only
70.150—SSB and CW only
70.200—SBB calling
70.260—All modes
70.300—RTTY calling
70.400—FM simplex
70.450—FM calling
70.500—end of band

Current 70 MHz beacons with power and beam heading are:
GB3CTC (70.300)—40 W, 45°
GB3WHA (70.040)—16 W, 315°
GB3BUX (70.080)—20 W, Omni
GB3ANG (70.060)—100 W, 160°

There are currently no repeaters operating in the 70 MHz band.

There are only two other countries with allocations in the 4-meter region. These are Gibraltar (ZB2) and Eire (EI). The opportunities for DX are correspondingly rare, therefore, although there have been reports of crossband contacts (70/144 MHz, 70/28 MHz, and, recently, 70/50 MHz) with Faroes (TF), Madeira (CT2), and Sweden (SM).

Despite low occupancy rates, 70 MHz does boast some of the less usual propagation modes with meteor scatter, auroral, and sporadic-E all featuring. Incidentally, the record distance for the last-mentioned mode is 745 km. Sporadic-E is also responsible for the frequent appearance in the UK of beacons ZB2VHF and EI4RFF (70.130 MHz).

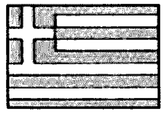
Perhaps the most endearing feature of the 4-meter band is its quietness and lack of crowding relative to 2 meters. This also can mean long periods when CQ calls remain unanswered.

There is little commercial equipment available for 70 MHz, with those few advertised items being of UK origin. (I have never seen any Japanese 4-meter gear advertised). Metalfayre of Dover produces 4-meter antennas with a 3-element version (7 dB gain) available at $40.00 and a 5-element version (9 dB gain) available at $64.00.

Wood and Douglas produces a range of 70-MHz modules that can form the basis of a home-brew rig. These include a 1.5-W transmitter ($50.00 assembled, $30.00 kit), an FM receiver ($90.00 assembled, $62.00 kit), and a couple of preamplifiers.

It is unlikely that 4-meter occupancy will increase significantly until the band is opened to class B license holders or more countries adopt an allocation in this part of the spectrum. Neither of these seems likely at present.

An interesting aside has just come to my attention via the RSGB hotline news service (a telephone answering machine at RSGB headquarters). British Telecom has just closed down its cable television service in Milton Keynes because they were unable to prevent egress of a 144-MHz signal. The Department of Trade and Industry will not permit the service to reopen until a new carrier frequency is implemented. Well, well!



GREECE

Manos Darkadakis SV1IW
Box 23501
Athens 11210
Greece

Now that the summer's here, maybe it is time for planning your annual vacation. Well, if blue sky, clear sea, and long sandy beaches appeal to you, then Greece is the place for you. You may also keep in mind that Greece has a lot to offer to a radio amateur, such as four separate DXCC countries to work from. These countries are mainland Greece (SV), Crete (SV9), Dodecanese Islands (SV5), and Mt. Athos (SV/A). Even if we have to leave the last one (hard to obtain a license), there are still the three to work from.

Things are much better now than they used to be a few years ago, and people have started to understand a bit more about amateur radio. There are many places such as hotels, bungalows, etc., where the owners allow an antenna to be erected and also will provide any help needed. I remember once, four years ago, while on vacation on the island of Cos (Dodecanese Islands), two people were fighting about who would have the privilege of having our antenna on top of his house!

So, do consider Greece as a possible place for your next vacation and don't forget to bring along your amateur gear, un-

less you have to choose between the radio and the XYL...

By the way, don't be surprised if you hear on the air a J4 prefix instead of the regular SV. Greece is issuing this prefix on special occasions, like contests, celebrations, etc.

Finally, we have two more countries that now have a reciprocal agreement with Greece. These are Sweden and the Federal Republic of Germany which, along with Cyprus, the USA, and Canada, make a total of five.

THE GOLD RUSH

DXpeditions still pay—especially when they are next door. DXpeditions have always had their own special kind of charm—not just the spirit of adventure, but also the fragrance of greenbacks. With a large number of affluent amateurs looking for more contacts to complete their single-band/multiband DXCC, a number of standardized methods to promote DXpeditions have evolved over the past two decades.

It began with the loan of equipment, money, and manpower to the local amateurs. One or two of the sponsors, mainly from the US, would try to join in as members, although the leader would be an Indian. The beams were given as a gift after the event because they would cost more than their original cost to take back. The QSL manager to the expedition was generally one of the sponsors—so that's where the greenbacks ultimately landed.

With the natives getting wiser, they began organizing their own expeditions with equipment donated by foreign sponsoring groups. The ostensible purpose was to give the world contacts with a rare country. The resulting greenbacks now came into their hands and mostly covered their costs, but did not compensate for all the backaches and tribulations of the travel.

The latest revolution in equipment design has now made it possible for expeditions to be more cost-effective by making multiband/multi-operator, round-the-clock operation possible with simple hand-carried power sources. Indians have not been too slow in catching up with this advantage.

Two regions of India that have enjoyed separate country status for quite a long time are the Andaman-Nicobar Islands and the Laccadive Islands. They have always been targets for these promoters. And, luckily for country-hunters, that status has continued long after these islands became integral parts of VU-land. There was a move to do away with special callsigns for these areas, but the Federation of Amateur Radio Societies of India (FARSI) President M. V. Chauhan VU2MV pointed out to the government the need to continue special callsigns for these areas—advice which obviously was heeded.

Late in 1983, with barely a few weeks to go, the government decided to celebrate WCY with a general permission to all comers to operate for a 15-day period up to December 31, 1983, from the Laccadive Islands, 250 miles off the west coast of India. Every station would use VU7WCY suffixed by his own call letters. The first team of two men and a YL left promptly and claimed over 5000 contacts in CW/SSB modes. A one-man expedition followed before the year was out. Bowing to pressures, the Wireless Planning and Coordination Wing of the Ministry of Communications (India's FCC) extended the deadline to March 31, 1984, paving the way for one more team to raise the tally by a further 5000 contacts.

The dollars and IRCs have begun rolling in, and each team has begun responding to the QSLs that are flooding in. When the gold rush is over, it will be time for the expeditioners to reckon how worthwhile the trek to the west was!

IRAQ

Herbert Perkins WA2JRV
268 Sagamore Drive
Rochester NY 14617

During my last trip to Baghdad, I was privileged to be a guest at YI1BGD (Scientific Center, Box 5864, Baghdad) and to take photographs. I have fortunately been able to visit the station several times and I want others to understand some of the problems faced by the club in Baghdad.

To guarantee a QSL card, you must send three IRCs *dated after 1 July 1981*. The date is very important because ones issued prior to 1 July 1981 are not valid in Iraq. A self-addressed envelope and of course your card should also be sent.

The letter to YI1BGD should be addressed to the operator *but should not have a callsign* in the address. Do not send any money; it will not get to the club.

The club promises that any QSL cards received will be acknowledged, but everyone needs to understand that over 500 cards a month are received, of which 50% have IRCs and a return envelope, 20% have only IRCs, and 30% have no IRCs and no envelope. The club presently has over 2000 IRCs that are not valid in Iraq and cannot be used to defray the cost of QSLing.

The club is supported entirely by the 6 operators, and just the cost of postage for a one-year period is staggering. As a last resort, the club will send QSLs to the respective bureaus in each country, but this process can sometimes take up to 12 months to complete.

You might also be interested to know where all the club equipment comes from. The Drake C line was donated by JY1, His Majesty King Hussein of the Hashemite Kingdom of Jordan. The Atlas 210 was donated by the Radio Amateur Society of Yugoslavia. The Yaesu FT-101E was donated by JA1BK, the keyer by DL6QW, and the triband antenna and rotator were donated by the Northern California DX Association through OH2BH and the Radio Amateur Society of Finland.

The special call of YI1BIF was used November 3-20 to celebrate the Baghdad International Trade Fair.

JY9IU/HB9AIU and I assisted in setting up the station. Over 2000 contacts were made, and most QSLs should be answered by now.

YI1BGD is usually on the Arabian Knight Net at 0500 GMT two days a week and, if possible, every morning at 0500 to 0700 GMT on the Rare DX Net headed by JY3ZH. If time and operators permit, they are also on from 1500 to 1700 GMT Monday and Wednesday.

THE ITALIAN AFFAIR

I excuse myself with the readers not being able to write from Italy last month due to several reasons, the main of which is the effort spent with discussions and actions with other fellows directed to defend our rights and to restore our privileges at the same level as the other European countries.

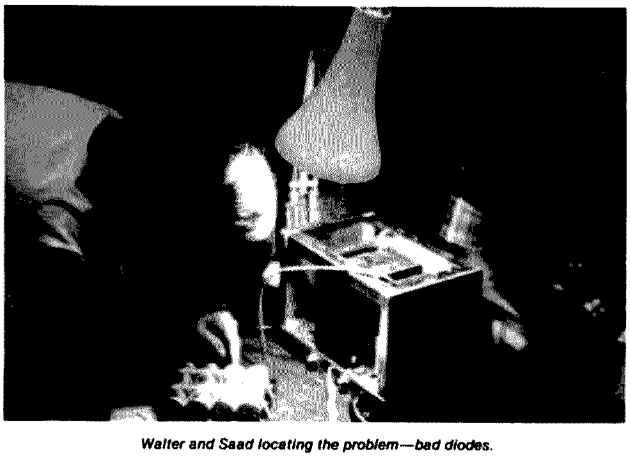
I have already explained what happened here in Italy: fines and license suspensions for amateurs who were found outside the borders of an ancient and outdated law and regulation. So much has happened during the last two months on this matter, and the situation, although improved, is still fluid. I will not now tell the story, which seems to be still susceptible to further development.

Nevertheless, the most important thing

Continued on page 102

Majied at the club station.

From the left: Walter Hediger, Herb Perkins, and Saad (operator at YI1BGD) repairing a dead L4B power supply.



Walter and Saad locating the problem—bad diodes.

Random VIC

Code-loving Commodore addicts asked for this. Ye shall receive.

Eugene Morgan WB7RLX
1311 Cross Street
Ogden UT 84404

For those of you who don't know who or what the VIC-20 is, it is the low-cost micro from Commodore, the makers of the Pet microcomputer. The VIC-20 is built around the 6502 chip and comes from the factory with 5K of memory, of which 3583 bytes are RAM. The VIC-20 can be expanded to 32K by the addition of memory expanders. The memory-expander cartridges can be plugged into the back of the VIC through the expansion port. They come in 3K, 8K, and 16K sizes and can be used alone or all together with a mother board to give you a total of 32K.

The VIC also has interface cartridges which can be plugged into the back of the user port. The VIC will interface through an RS-232 cartridge, an IEEE-488 cartridge, or through a phone modem. I have used the VIC phone modem to plug into one of the many computer services and it works very well. The phone modem comes with the necessary software to turn the VIC into a terminal. As of yet, I have not used the VIC for RTTY or ASCII over the ham bands.

Data or program storage can be saved on the VIC floppy disk or the VIC cassette drive. Also available for the VIC-20 is the VIC printer. It can be used to list programs, or the contents of the screen can be sent to the printer.

The VIC comes with all the necessary cord and filters so that the home TV can be used for the video display, or a color monitor can be used with no external interfacing. The screen size is 22 columns by 22 rows which sometimes can be an inconvenience. The Commodore people say there is a cartridge, the

```

Victerm-40, that gives the VIC a 40 by 22 screen. As of this writing, I have not used it.

The VIC-20 can be programmed in Basic or machine language. It is very easy to mix Basic and machine language together in a program by the use of a simple command, SYS.

The Program

I chose Basic for the random code-practice program because it would be easy to adapt to other computers and also because speed of execution was not an important factor. No memory expansion is needed to run this program. If you are using expansion cartridges, they should be switched off or removed. This program takes only 2227 bytes.

The code-practice program sends a random code at whatever speed you select. You will be prompted for a sending speed from 5 wpm to 35 wpm in steps of 5. The code sound is made at the same time as the letter is printed on the screen. Printing the symbol at the same time as it is sounded can be very helpful when trying to associate the symbol with the sound.

If you prefer, you can blank out the screen so that you cannot see the symbols being printed until you stop the program. The method for doing this is as follows.

First, when you reach the part of the program that asks you for a speed, type in your selection—but before you press RETURN, change the cursor to white. This is done by pressing the CTRL key and 2 key together. This will make the cursor disappear. Now all symbols will be printed the same color as the screen. In order to see what has been printed on the screen, you must stop the program by pressing any key; then hit the RUN STOP key. Then POKE 36879,8 and the screen will turn back and you will see what has been printed.

To rerun the program, press the RUN STOP key and the RESTORE key together. This will change the screen back to white and go back to the first of the program.

The way the program is set to run is as follows. First, the program gives my information. By pressing any key you move into the program. You will be prompted for a speed. A menu will be printed on the screen for your selection. Enter your choice and press RETURN. The screen will clear and you will hear a code and the symbols will appear on the screen in groups of five. Be sure to turn the volume on.

When you have copied enough, just press any key. The code will stop and you will be asked if you would like to select a new speed. If you do, then just press any key. The screen will clear and you will again be given a selection from 5 wpm to 35 wpm.

The first part of the program, lines 1-3, deals with my information. Line 4 sets the volume on the VIC; 15 is as high as you can go. Lines 5-7 are the Gosubs. I placed the Gosubs at the beginning of the program as a memory-crunch procedure to conserve memory. It would have taken more memory and more typing time if I had used three-digit numbers.

Line 19 is an instruction prompt for halting the program. Lines 20 and 21 print the speed menu. Line 25 asks for your choice. Line 22 sets the pitch of the sounds. You can change the pitch of the Dah and Dit by POKEing 36875 to any value from 128 to 255.

Lines 26 through 32 set the length of T%. T% is used to set the lengths of the Dit, Dah, and the spaces. You can change the speeds by changing the value of T%. Line 40 sets the length of the Dah and Z%. Z% is three times longer than T%. This will make the Dahs three times longer than the Dits. Line 40 also sets the value of S% which is the length of the space between words. S% is four times longer than T%.

Line 50 is the space between each symbol. Lines 60 through 109 are the symbols with the Gosubs to get each Dah and Dit. Line 100 is the blank space between the groups. Line 150 tells the VIC to go back and count to T% and delay between symbols. Line 850 looks to see if

READY.
```

a key has been pressed. If one hasn't been pressed, then the program goes to line 900, at which point a random number between 1 and 90 is generated.

Lines 901 to 905 take care of the numbers that we can't use in our program. Line 907 keeps track of the number of symbols printed since the last space. Line 908 tells the VIC what to do after it has printed five symbols. Line 950 turns our random number into a symbol and then sends the VIC back to line 60 where it will look for the symbol it has just printed. The program will stay in this loop until a key is pressed. If a key is pressed, line 850 will send the VIC to line 1200 where it will stop the code and print an instruction prompt. Line 1205 will wait for you to press a key. If a key is pressed, the VIC will go to line 19. At line 19, the VIC will start the routine to get a new speed.

I have used the random-code program for almost a month now and have improved my speed by ten words a minute. I hope that you will find the practice as helpful as I have. I haven't used this program on any prospective hams yet, but I have made several code tapes from this program and given them to some of my ham friends. So if your friend doesn't have a VIC, he can take advantage of yours.

I have also made other programs for the VIC-20 for use by the amateur-radio operator. The Ham Log is a program that will keep track of your QSOs by call and state or country. Information can be recalled by typing in a call or a state or a country. Any data can be listed for each station you work. Such data could include the operator's name, address, phone, frequency, rig and antenna, or any interesting tidbit you wish. Data can be updated without any hassle.

Antenna Program

Another very useful program is the antenna-design program. All you do is input the type of antenna and its frequency. I have built some of the antennas and found them to work very well. This program could be very useful to the ham who likes to build his own.

Programming Can Be Fun

I have a very good time experimenting with the VIC. Sometimes it can be frustrating when something you thought would work doesn't and nothing you try will work. You have to scrap the idea and try the same thing from another angle. Then when it does work, it can be very satisfying.

The VIC is, at last, a computer that most people can afford (under $300) and it can get you started in the world of computers. At first, the programs can look very strange with all the Gosubs and Gotos, the POKEs and PEEKs, and all of the other computer jargon. But it will surprise you how fast you can pick it up, and you will be writing your own programs in no time at all.

If you are a ham who just doesn't think that you could use a computer, then I am here to tell you that there are many uses for one in the ham shack even if you never use it on the air. I am sure that after you get the hang of programming—and you don't need to be an expert—you will find many other uses for it around the house. One word of caution: it can be addicting!

If you have any questions or some problems with the random code-practice program, please let me know. ■

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

MAPLE RIDGE BC CAN
JUN 30-JUL 1

The Maple Ridge ARC will host Hamfest '84 on June 30-July 1, 1984, at the Maple Ridge Fairgrounds, 30 miles east of Vancouver. The registration fee is $5.00 for hams and $2.00 for non-hams over 12 years old. Features will include a swap and shop, commercial displays, bunny hunts, and ladies' and children's programs. Food and camper space with electricity will be available. Talk-in on 146.20/.80 and 146.34/.94. For more information or preregistration (20% off gate fee), contact Maple Ridge ARC, Box 292, Maple Ridge BC V2X 7G2.

OVERLAND PARK KS
JUL 4-7

The Mobile Amateur Radio Awards Club, Inc., will hold their annual convention from Wednesday to Saturday, July 4-7, 1984, at the Holiday Inn in Overland Park KS. There will be a picnic for early arrivals on Wednesday evening, and on Thursday there will be area tours and a dinner theater. On Friday there will be antenna and computer forums, and on Saturday morning the annual business meeting will be held. The hospitality suite will be open during the entire convention. For more information, send an SASE to R. L. Dyson KØAYO, R1, Box 230 M, De Soto KS 66018.

MAHOPAC NY
JUL 7

The Putnam Emergency Amateur Repeater League (PEARL) will hold its 3rd annual hamfest on Saturday, July 7, 1984, from 9:00 am to 4:00 pm, at St. John's School Monsignor O'Brien Boulevard, Mahopac NY. General admission is $1.00, indoor tables are $5.00 each, and outdoor tailgating is $4.00. Talk-in on 144.535/145.135 and 146.52. For advance registration and more information, contact Frank Konecnik WB2PTP, RD1, 244 C, Carmel NY 10512.

FARIBAULT MN
JUL 7

The Faribault Amateur Radio Club will hold its 3rd annual swapfest on Saturday, July 7, 1984, from 9:00 am to 3:00 pm, at Rice County Fairgrounds, Faribault MN. Tables are available only by reservation before July 1st. Talk-in on 146.19/.79. For more information, contact Mike Ferguson NØDGG at (507)-744-5145 after 5:00 pm.

OAK CREEK WI
JUL 7

The South Milwaukee Amateur Radio Club will hold its annual swapfest on Saturday, July 7, 1984, from 7:00 am to approximately 5:00 pm, at the American Legion Post #434, 9327 South Shepard Avenue, Oak Creek WI 53154. Admission is $3.00 per person and includes a "Happy Hour" with free beverages. Parking, a picnic area, hot and cold sandwiches, and liquid refreshments will be available. There will be free overnight camping. Talk-in on 146.94 MHz FM. For more details, including a local map, write South Milwaukee Amateur Radio Club, PO Box 102, South Milwaukee WI 53172.

INDIANAPOLIS IN
JUL 7-8

The State ARRL Convention and the Indianapolis Hamfest will be held on Saturday and Sunday, July 7-8, 1984, at the Marion County Fairgrounds at the southeastern intersection of I-74 and I-465. Gate tickets are $4.00 and entitle you to free parking and all activities. Flea-market and commercial vendors may set up at 8:00 am on Saturday, July 7th. Security will be provided Saturday night and Sunday, and free camper facilities and hookups will be available on the grounds. The commercial building will be open to the public at 8:00 am on Sunday, July 8th. There will be technical forums all day Sunday, and professional food service will be provided. For further information, contact Indianapolis Hamfest, Box 11086, Indianapolis IN 46201.

ALEXANDER NY
JUL 8

The Genesee Radio Amateurs, Inc., will hold the Batavia Hamfest on Sunday, July 8, 1984, from 7:00 am to 5:00 pm, at the Alexander Firemen's Grounds, Rte. 98, Alexander NY. Admission is $3.00 in advance before June 22, 1984, and $4.00 at the door. The commercial exhibit area will open at 9:00 am and there will be hot-air-balloon rides. Activities will include breakfast at 6:00 am, a CW contest, OM and YL programs, a .52 check-in contest, a flea market, a chicken barbecue, and free camping (electricity is $2.00). Talk-in on 6.52 and 4.71/5.31 (W2RCX). For further information, contact GRAM, PO Box 572, Batavia NY 14020.

BOWLING GREEN OH
JUL 8

The 20th annual Wood County Ham-A-Rama will be held on Sunday, July 8, 1984, beginning at 8:00 am, at the Wood County Fairgrounds, Bowling Green OH. Admission and parking are free. Trunk sales and food will be available. Advance table rentals are $5.00 and are for dealers only. Saturday will be available for setups until 8:00 pm. Talk-in on .52. For more information or dealer rentals, send an SASE to Wood County ARC, c/o Craig Henderson, Box 366, Luckey OH 43443.

SHEBOYGAN WI
JUL 14

The fifth annual Sheboygan County Amateur Radio Club Lakeshore Swapfest and Brat Fry will be held on July 14, 1984, from 10:00 am to 4:00 pm, at the Wilson Town Hall, south of Sheboygan WI. Tables are free and camping is available at Terry Andre State Park. For a flyer and other information, write Julian E. Jetzer KR9S, 6400 Hawthorn Road, Sheboygan WI 53081, or phone (414)-457-3366 after 5:00 pm CDT.

MILTON ONT CAN
JUL 14

HAM HELP

I need a schematic and manual for my Tempo FMH-2, two-meter HT. I also need a good (unbroken) battery tray for same. Please advise of your costs when replying. Thank you.

Randy W. White KB4ALH
506 Robinhood Drive
Seneca SC 29678

Twenty years ago, I read an article on how to convert a TV to an oscilloscope. I have three old B&W TVs which I'd like to convert to some type of test equipment, but I don't know how. Can anybody help?

Guy Milne W2BPN
32 Stag Trail
Fairfield NJ 07006

I am in desperate need of a 5BP4, 5BP1, or equivalent CRT for my Eico model 425 oscilloscope. Any information on where I can find or purchase one would be greatly appreciated.

Ira Linderman
PO Box 229
Commack NY 11725

I need copies of several pages from the manual for the AN/USM 281A oscilloscope (military version of the Hewlett-Packard HP180). I also need some pages from the service manual for the Motorola Mocom 10.

John Tobin KF4WG
6726 Cocos Drive
Orlando FL 32807

I need a schematic or service manual for the Com-Data model 301F2 modem and the Com-Data model 201F4-13 modem. I am also trying to find a current address for Jim Labo KØOST/ex-WB8IDD.

John Hackman WB4VVA
5290 East Valley Road
Mount Pleasant MI 48858

I am looking for the service manual for the NCX-3, or schematics for the power supply for the NCX-3 (by National).

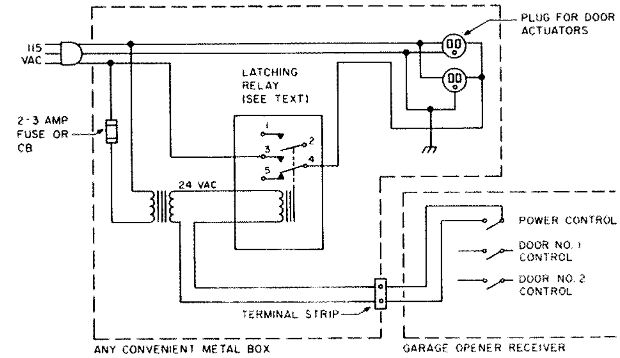
The Northcentral Montana Hamfest will be held on August 17-19, 1984, in Beaver Creek Park at Marden's Campground, 28 miles south of Havre MT.

✓ See List of Advertisers on page 98

CIRCUITS

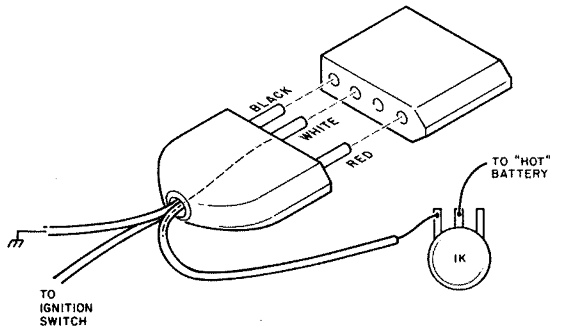
Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*

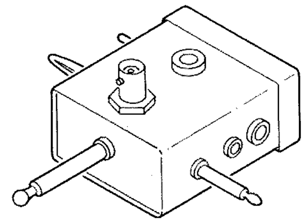


A GARAGE-DOOR OPENER CAN DO MORE: You can make the spare channels on a garage-door opener with the circuit shown here. Anything you want can be turned on or off, as long as it is within the amperage capability of the relay. One part, the latching relay, can be found at Heath (part #273-3). The transformer to operate it is part #273-4.—James Smith K5PTC, Irving TX.

ANOTHER HEAT CONTROL FOR A SOLDERING IRON: This control uses a solid-state dimmer switch. These high-low rotary dimmer switches will control resistance loads of up to 600 Watts. Wire one up with a fuse in a small utility box and you will have an infinite heat control for soldering. Incidentally, if you use a dimmer switch rated at 600 Watts, it can also be used as a speed control for your 3/8-inch electric drill.—E. A. Rowe W7PWQ, Chelan WA.



PERMANENT POWER FOR THE IC-25A/H: Here's a way to keep your memory without having to worry whether you left the radio on. Add a third connection in the power plug as shown. Connect this to a continuous 12-V source through a suitable resistance to drop it to 9 V (I used a 1k trimmer adjusted to 670 Ohms). Connect the normal power lead of the radio to an appropriately-switched 12-V source, and the memory will receive power even when the radio is turned off.—Virginia Smith KA6NVB, San Diego CA.



MULTIPLE PLUG ADAPTER: After years of struggling to find the right adapter for the right piece of gear, I built one that handles many types of connections. I took a small hinged-lid box, like the boxes that small bandages come in, and mounted a phone plug on one end. Then I added a variety of different sockets on the sides of the box. I included BNC and RCA connectors, pin jacks, small sockets, and banana jacks. Now I save a lot of time when servicing and testing.—Wm. Bruce Cameron WA4UZM, Temple Terrace FL.

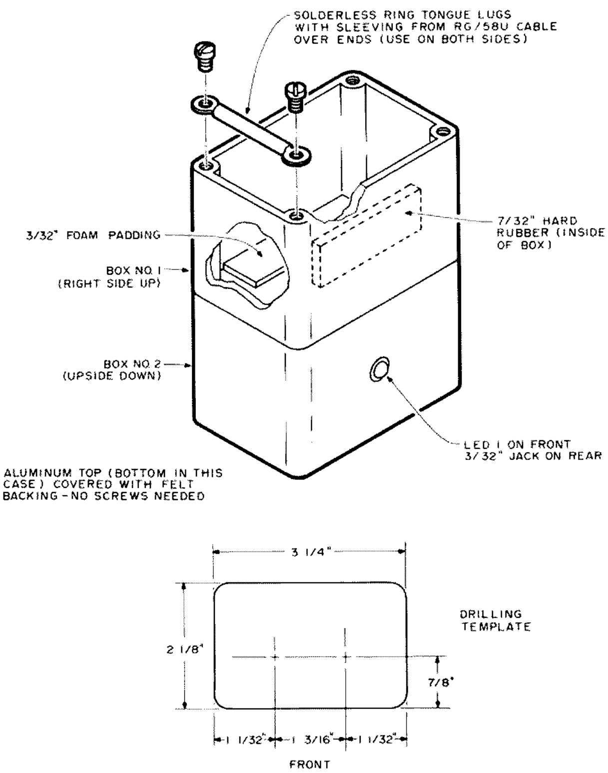


Fig. 1. Mechanical details.

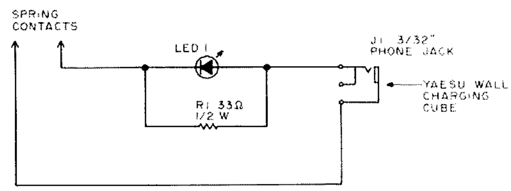

Fig. 2. Charger schematic.

STAND-UP CHARGER FOR YAESU HTs: Inexpensive Radio Shack parts can be used to make a charger for the Yaesu FT-208R transceiver. Small screws (such as 6-32 MS) are threaded through both boxes (RS #270-230) using the drilling dimensions shown in Fig. 1. Matching spring material is threaded onto both screws to make contact with the charging buttons on the bottom of the FT-208R. Experiment to get the best contact, then add rubber padding to the top box to obtain a snug fit. The charging circuit in Fig. 2 will drop the normal charging current about 10 mA, from 45 mA to 35 mA, which will increase the total charging time. J1 is RS #274-292, R1 is RS #271-007, and LED1 is RS #276-069. The LED will glow only when proper contact is made with the bottom contacts of the HT.—David F. Miller K9POX, Niles IL.

BARTER 'N' BUY

Individual (non-commercial) .... 15¢ per word
Commercial .... 50¢ per word

Prepayment by check or money order is required with your ad. No discounts or commissions are available. Please make your payment to *73*. Rates for multiple insertions are available on request.

Advertising must pertain to amateur radio products or services. No special layouts or positions are possible. All advertising copy must be submitted typewritten (double-spaced) and must include full name and address. Copy limited to 100 words, maximum. Count only words in text. Address, free.

73 cannot verify advertising claims and cannot be held responsible for claims made by the advertiser. Liability will be limited to making any necessary correction in the next available issue.

Copy must be received in Peterborough by the 5th of the second month preceding the cover date.

MOBILE IGNITION SHIELDING. Free literature. Estes Engineering, 930 Marine Drive, Port Angeles WA 98362. BNB006

COMPUTER OWNERS! Super new MFJ 1224 CW/RTTY/ASCII terminal units. Send/receive CW/RTTY/VIC-20 and Commodore 64 software. Full-featured, disk or cassette. Kantronics, too. Low prices, speedy delivery. Hundreds sold internationally. SASE for details and catalog of Commodore, Atari, PET, ZX-81, TI, TRS-80 software and accessories. Amateur Accessories, 6 Harvest Court, RD 7, Dept. BB, Flemington NJ 08822. Telephone (201)-782-1551, 6:30-10:30 Eastern time. BNB019

WANTED: Cash paid for used SPEED RADAR EQUIPMENT. Write or call: Brian R. Esterman, PO Box 8141, Northfield IL 60093; (312)-251-8901. BNB030

MILITARY TECHNICAL MANUALS for old and obsolete equipment. 60-page catalog, $3.00. Military Technical Manual Service, 2266 Senasac Ave., Long Beach CA 90815. BNB045

WANTED—your unused Teletype™ repair parts. High prices paid! Send SASE for list of Teletypewriter parts and supplies. TYPETRONICS, Box 8873, Fort Lauderdale FL 33310; (305)-583-1340 after 9:00 pm. N4TT. BNB052

WANTED: Pre-1950 TV sets and old *TV GUIDE* magazines. W3CRH, Box 20-S, Macomb IL 61455; (309)-833-1809. BNB066

1984 WIRE & CABLE prices cut!!! Call or write for latest listings. Certified Communications, "The CB to 10 Meter People," 4138 So. Ferris, Fremont MI 49412; (616)-924-4561. BNB073

EMERGENCY COMMUNICATIONS—An Organizational and Operational Handbook, by K3PUR. A complete reference guide for ARES/RACES and other public service groups, as reviewed in December '83 *QST* and January '84 *CQ*. $9.95 plus $1.50 P/H to: FDW Arts, 1394 Old Quincy Lane, Reston VA 22090 (VA residents, add 4% tax). BNB089

DX HEADING MAPS for Boston, NYC, Philadelphia, Baltimore, Detroit, Atlanta, Chicago, New Orleans, St. Louis, Dallas, LA. 11" × 17", $1.75 pp. 22" × 34", $5.95 pp. Specify city. Massey, PO Box 397, Hainesport NJ 08036; (609)-261-2952. BNB094

STATE-OF-THE-ART, rugged, low-profile antenna systems. Helical designs from 3.5 to 50 MHz. DDRRs from 144 to 450 MHz. Refer to *73* magazine reviews in October and November, 1982. Com-Rad Industries, 25 Imson Street, Buffalo NY 14210; (716)-773-1445. BNB096

ANTI-STATIC DUST COVERS by Cover Craft Corporation. Amateur radio, computers, printers, disk drives, VCRs. New or older models. Over 1,000 designs in stock and over 1,000,000 in use. Call or write for brochure. Birch Hill Sales, PO Box 234, Peterborough NH 03458; (603)-924-7959. BNB097

FIND OUT what else you can hear on your general-coverage transceiver or receiver. Complete information on major North American radio-listening clubs. Send 25¢ and SASE. Association of North American Radio Clubs, 1500 Bunbury Drive, Whittier CA 90601. BNB099

MAGICOM RF SPEECH PROCESSORS—Add 6 dB of average output with genuine rf clipping in your transmitter's i-f stage. Custom engineered for Kenwood TS-120, TS-130, TS-430, TS-520, TS-530, TS-820; Drake T-4X, TR-7; Yaesu FT-102. Excellent speech quality, simple installation, affordable prices! SASE for data and cost. Magicom, PO Box 6552A, Bellevue WA 98007. BNB101

ELECTRONIC AVOCATIONS™. Nonprofit service promoting radio hobbies. SASE. Arnold Timm, 2308 Garfield #304, Minneapolis MN 55405. BNB106

FM SERVICE MANUALS—RCA, GE, Motorola, Aerotron, Alpha, Johnson, Kaar, DuMont, others. Reasonable. Send exact model and description. T. McLaughlin, PO Box 411, Mango FL 33550. BNB110

IMRA—International Mission Radio Association helps missionaries by supplying equipment and running a net for them daily except Sunday, 14.280 MHz, 1900-2000 GMT. Br. Bernard Frey, 1 Pryer Manor Rd., Larchmont NY 10538. BNB123

WANTED: Model 8010 remote vfo for Tempo 2020 xcvr. Call collect (913)-267-1575 or Compuserve E-mail user no. 71336,1270. Will pay all shipping charges. Tim Gorman WAØLYJ, 3758 Humboldt, Topeka KS 66609. BNB125

ICOM AND KENWOOD OWNERS! You are definitely missing out if you do not receive our very informative newsletters! Free information! Send SASE (2 stamps) to International Radio, Inc., 364 Kilpatrick Ave., Port St. Lucie FL 33452. BNB129

BUY-SELL-TRADE twice monthly publication! SASE for FREE issue. *The Ham Boneyard*, 364 Kilpatrick Ave., Port St. Lucie FL 33452. BNB130

WANTED: Collins KW-1 transmitter. Paul Kluwe KB8Q, Box 84, Manchester MI 48158. BNB147

GROUND RADIALS WORK—Solve your vertical antenna problems with the fantastic ground plane one (GP-1). A 10"-diameter, 24-point cast-aluminum bus that fits any 2"-diameter or smaller mast. Radial problems solved for only $24.95. Send an SASE for photos and brochure. Lance Johnson Engineering, PO Box 7363, Kansas City MO 64116. BNB148

CDE ROTOR OWNERS—You need a "D-Lay-5!" This easy-to-install circuit protects the rotor from damage caused by accidental braking. Works with the Ham II, Ham III, Ham IV, and Tailtwister models. Provides a five-second safety factor in your rotor brake. Incredible value at $19.95. Postage paid worldwide. Lance Johnson Engineering, PO Box 7363, Kansas City, MO 64116. BNB149

ELECTRON TUBES: Receiving, transmitting, microwave . . . all types available. Large stock. Next-day delivery in most cases. Daily Electronics, 14126 Willow Lane, Westminister CA 92683; (714)-894-1368. BNB150

JOHNSON 6 & 2, $35. Johnson Matchbox, $25. RCA mobile test set, $15. CRT test set, $10. Knight tube tester, $15. K6KZT, 2255 Alexander, Los Osos CA 93402. BNB151

WANTED: copy of service manual and schematic for Fairchild TV Camera TC-177RL. Will pay for copying. L. Ferguson WBØPXQ, Route 1, Brady NE 69132. BNB152

SCIENCE SOFTWARE for VIC-20 and PC-2. Radio astronomy, moonbounce, amateur satellites, etc. David Eagle, 7952 W. Quarto Dr., Littleton CO 80123; (303)-972-4020. BNB153

TEST EQUIPMENT. Measurements 920 deviation meter—$325. Measurements 801A FM sig gen—$400. Measurements 560 FM sig gen—$250. Marconi TF1066A AM/FM, 10-470-MHz sig gen—$350. Simpson 160 VOM—$25. Systron-Donner 1037/1292 15-GHz counter—$500. SASE for list. Brian Whitney, 2490 Madison Ave., Yuma AZ 85364; (602)-726-8753, eves, wknds. BNB154

WANTED—Gilfer Associates GAR-7 frequency counter for Yaesu FRG-7 receiver. Also, frequency counter for Heathkit HW-101. George Ellison, Rt. 1, Box 146-B, Eatonville WA 98328. BNB155

HW-101 OWNERS! Put RIT in your transceiver for under $10. Plans, $6. B. Bennett, Box 201, Alexandria Bay NY 13607. BNB156

BEAT the over-priced antenna market. We manufacture antennas and kits, and stock a wide variety of 6061-T6 .058-wall aluminum tubing. Use our concept and only your imagination will be the limit. Write Antenna Dimensions, PO Box 340, Germanton, NC 27019. BNB157

WANTED: pre-1950 bugs and pre-1925 wireless keys for my collection. Neal McEwan K5RW, 1128 Midway, Richardson TX 75081; (214)-234-1653. BNB158

FREE CATALOG—computer supplies. Control Data SS/DD, $21; DS/DD, $31. Dysan SS/DD, $30; DS/DD, $40. Ribbons: MX80, $7.50; MX100, $14; Okidata 82-92, $2.50; Okidata 84, $5.00; Diablo Hytype II m/s, $4.40; Diablo Hytype II nylon, $4.80; NEC Spinwriter m/s $4.75; 6-outlet surge and spike power strip, $49.95. Shipping, $3.00. Mastercard/Visa—include number and expiration date. OUTPRINT, 44 Forrest Road, Randolph NY 07869. BNB159

"ELECTRONIC BONANZA." Icom, Sony, Kenwood, Yaesu, Uniden, Panasonic, Bearcat, Regency, MFJ, CBs, antennas, coax, CW/RTTY decoders, marine, much more!! Free UPS shipping and insurance to 48 states. 25-page picture catalog, $1.00 (refundable). Galaxy Electronics, Box 1202--, 67 Eber Ave., Akron OH 44309; (216)-376-2402, 9:00-5:00 EST. BNB160

DIGITAL AUTOMATIC DISPLAYS for FT-101s, TS-520s, Collins, Drake, Swan, Heath, and others. Six ½" digits. Write for information. Grand Systems, Dept. A, PO Box 3377, Blaine WA 98230; (604)-530-4551. BNB161

RADIO SHACK dealer, large computer discounts. Ben Dickerson K3DQU, Box 520G, Starke FL 32091; (904)-964-7474. BNB162

SHAKEOUT . . . Sudden unemployment? Retirement? Security alarm systems easily learned. Business-residential installations . . . easy, enjoyable, fascinating, extremely profitable, rewarding work. Age not important. Information that could secure, improve your future, $2.00. Security Electronics International, PO Box 1456-W, Grand Rapids MI 49501. BNB163

C-64 AND VIC-20 ham software: new contest-II program, call-name-QTH log program, ham formulas program, much more, LSASE for list. Specify computer. Walt KA9GLB, 4880 N. 49th St., Dept. 7, Milwaukee WI 53218. BNB164

THE BIG ONE for Indiana, the WA8VZY repeater serves at least 46 counties from nearly 1500 feet above sea level at Fairland. Try the "Mighty 525" (144.65 in/145.25 out) on your next trip through the central half of Indiana. Transients, repeater DXers, and aeronautical mobiles all welcome. Full autopatch privileges, covering 102 greater Indianapolis exchanges, available for the rest of 1984 for $12. Donations sincerely appreciated. Send to: Bob Hawkins, WA8VZY, Box 19255, Indianapolis IN 46219. BNB165

QSLs AND RUBBER STAMPS. Top Quality. QSL samples and stamp information, 50¢. Ebbert Graphics, D-7, Box 70, Westerville OH 43081. BNB166

COMMODORE 64 CW INSTRUCTOR PROGRAM. Generates CW on TV speaker. Random code, keyboard input, or prerecorded "CW tests." Character speed and spacing set independently. Designed for classes and increasing code speed. $15.00, diskette or cassette (specify). Dennis Olver N7BCU, 20909 S. Ferguson Rd., Oregon City OR 97045. BNB167

FOR RENT: "Ham-Home," northern Virginia, five miles southwest of Pentagon, three bedrooms, "family room," 50-foot telephone pole, tribander, 14-el two-meter, 40/80-meter dipole, ½ acre, fenced yard. Available August '84. K1CTK/4. Use *Callbook* address. Phone (703)-379-7437 evenings. BNB168

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

have about 500 high schools that have ham clubs today. In Japan, there are over 5,200 high schools with ham clubs. And in Japan, when *they* have a *club*...how many of you have ever seen a copy of the Japanese *CQ ham radio* magazine? Runs six or seven hundred pages a month with about a hundred pages of club activities with pictures of maybe 50 to three or four hundred people in the group all having a whale of a time. *Every month.* It's like Dayton every week.

So I hope to do something about that. What I would like to do eventually is to encourage *every high school* in the United States to have a period of their school—one period during school hours—set aside for a high-tech hobby club, amateur radio, computer, astronomy, whatever.

If you make it after school, you run into two problems which are not surmountable. Number one is busing. Number two is overtime pay for teachers. If it's after school, the unions require that they get overtime and that's not in the school budget.

So let's make the club *during* school hours. And I'll bet you if we do that, that we can get virtually every ham club in the country to volunteer somebody to go in and help those students learn and know more about amateur radio. I *know* that I can get the computer-club people to go in and help with the computer clubs.

The rules and regulations. I don't know how many of you have read 97 recently. Not many, I'll bet. But right there up front, 97.0 gives reasons why amateur radio is a service. One reason is to supply communications in case of an emergency. Another reason is to invent and pioneer new technology. Another reason is international friendship.

I'd like to just speak briefly on that [97]. I don't know how many of you operate 20 meters and have listened to the pileups...the list operation on the contests. As far as international friendship is concerned: hardy, har, har, har. [Guffaws.]

Inventing and pioneering new technologies. About 20 years ago, we were pretty good at that. We invented and pioneered single sideband. We invented and pioneered narrowband FM. And, as they say, what have *you* done for us lately? *Not much.*

Unfortunately, most of the pioneering, most of the inventing, is done by youngsters. And we have stopped having youngsters coming into the hobby.

Our country has lost over one *million* engineers and technicians that would have come into the industry by way of amateur-radio-starting. And that's why we are not designing or building very much electronic equipment or that has a lot to do with it.

I hope we can reverse that. Have you seen any military equipment lately? It's all high-speed digital. How many people here are on high-speed digital? Thank you. We have one person here who might be of value to the military. No, forty years ago when we had a war you read about it in the papers; 80 percent of the hams volunteered and went into the military. And we were *of value*.

But we are so hopelessly out of touch with electronic technology today and unfortunately such a high percentage of us are in our 50s, 60s, and 70s, and 80s that we're really not of much value to the country any more as a supply of trained operators. [Grumbling.]

That leaves us with emergency communications. The replies that were sent to the FCC by about a hundred ARRL clubs on the no-code proposal were very clear. And they said in essence (and I would say they said very clearly) that we need Morse code because it's the only means of communication of last resort. When everything else fails, you have Morse code.

I would like to see somebody convert a transistor radio for CW. I would like to see somebody take an HT and dust it off after the atomic attack and try to make it work on Morse code. Because that's what we're going to have, mobile rigs and HTs.

Yes, 30 years ago when you had tube radios, you could wire something up and make a Morse-code transmitter out of it. And we have all those people that used to be able to do that commenting on the no-code license. I look and see what Japan has done with that and the supply of Japanese licensed amateurs increasing from 18,000 to one and a quarter million at the same time that we went from 285,000 to 400,000.

And (unfortunately) they are the best operators in the world. For those who say you must have Morse-code skill in order to be a good operator, I've never seen any correlation.

Now, I don't know if no-code would work in this country or not and would make a difference and would encourage people to get into amateur radio. But I think it's worth a try.

If Morse code is that important and if that is what we are going to have to depend upon when the atom bombs fall (for communication), I don't see any other choice but to make sure that every amateur is *very, very* good at Morse code. You don't really have any choice.

You've *got* to be good at it because you're going to have to handle millions of messages. You're going to have to handle an *incredible* amount of messages.

I've just made a note of a few of them. You've got to handle traffic about radiation and where the detectors are, military communications, law and order communications, food, water, shelter, clothing, medical help, medical supplies, evacuation, toilet facilities, power, getting equipment around where it is needed, travel communications, and so forth.

You've got an enormous amount of things you're going to have to handle.

Anybody who has done emergency communications knows what I am talking about. You are immediately overloaded enormously and hams have to work 36 hours at a time without stopping and they still fall way behind on trying to keep up with *minor* emergencies. And we're talking about—now—when the chips are down. We're talking about being able to supply emergency communications in case of nuclear attack. And we can't *plan* for anything *less*.

We have painted ourselves into a corner that we can't get out of on that. There is no way that we can provide even a fraction of what is needed. And we have stopped ourselves from essentially being able to do anything about it.

What *could* we do? We could start working toward high-speed digital communications with little units maybe a third the size of the Model 100, where you can write messages. And we can have our repeaters so they relay them automatically, as I said before. And all of this, if we have enough *hams*, will be done very inexpensively, will be done with single chips.

Think of the communications facility we would have if you could pick virtually anybody that you wanted to talk with and write a message to him and have it automatically delivered. It would be a different kind of amateur radio.

If we tuned 15 meters and every time you came across a signal, the call letter flashed on your transceiver on a little readout because he's sending his call automatically on a subcarrier at high speed...and it would read out and you could tune, you could have, you could punch in on your keyboard, the prefix that you're looking for. You could work all 350 countries in alphabetical order [chuckles]—in a day, if there's a few DXpeditions out there. And at the DXpedition, all you have to do is send the box and have an automatic flip-up antenna at the post office. [Guffaws.] And have a little chip in there that prints out the awards certificate when you contact the station automatically. [Guffaws.]

Well, I joke about it, but it isn't that far off. We *could do that.* And *indeed*, if we *don't* have a *system* that can handle that quantity of communications and do it *automatically* and not insist on having a *skilled* operator present, we're not going to be able to provide the communications that are needed.

Now, it's up to us to design equipment, to buy it, make it

work, and have it ready, but it should be capable of being operated by anybody.

Questions

Just one comment: Sixty million is kind of Mickey Mouse, isn't it?
I don't know, it seems kinda good. [Guffaws.] I haven't had any emotional problems with it. [More.] I guess the main people who have had emotional problems with it are the people around me because I haven't changed much. I still live in a one-room apartment over my office and everybody says, "Gee, you're so wealthy, you should have an estate and everything like that." It isn't that bad. Yeah?

Yeah, you talked about in one of your editorials about liking all these gadgets. I just wonder how you fit them all in?
Well, fortunately the gadgets that I like are all very small. And it's not that much of a problem. Everything is, you know, they're all small. I'm a gadget fanatic—but, very few large gadgets. Yes?

You're still the owner of 76, aren't you?
Pardon me?

You still own 76?
73? No, I sold 73. I am still the publisher and president of the corporation but it is *owned* by IDG. And we changed the name of it to CW Communications in honor of Morse Code. [Guffaws.] You notice my little key up here. [Gold lapel pin.]

. . . I thank you all very much for coming. If you have any further questions, come up here and ask them. [Applause.]

VENEZUELAN INDEPENDENCE WORLDWIDE CONTEST
SSB
Starts: 0000 GMT July 7
Ends: 2400 GMT July 8
CW
Starts: 0000 GMT July 28
Ends: 2400 GMT July 29

The Radio Club of Venezolano invites all amateurs to participate in the 22nd year of the Venezuelan Independence Worldwide Contest. Use all bands, 80 through 10 meters. Operating classes include: (a) single operator, one band (for each band); (b) single operator, multiband; (c) multi-operator, multiband, one transmitter; (d) multi-operator, mulitband, multi-transmitter.

EXCHANGE:

RS(T) plus a three-digit QSO number starting with 001.

SCORING:

Contacts between stations of different countries count two points. Contacts with stations within one's own country do not count but are valid as multipliers for each band. Count one multiplier for each Venezuelan and USA call area and each country (including own) worked on each band. Use the ARRL DXCC country list. Final score is the total QSO points times the total multiplier points.

AWARDS:

For stations outside Venezuela, there will be a plaque to the highest scorer in each class. Medals to the highest scorer in each continent and among the Bolivarian countries (Bolivia, Colombia, Ecuador, Panama, and Peru) in the single-operator, multiband class. Certificates to all stations in the Americas working 15 YV stations and 10 different countries, all European and African stations working 10 YV stations and 10 different countries, and all Asian and Oceanic stations working 5 YV stations and 10 different countries.

ENTRIES:

Logs must show date and time in GMT, station worked, reports exchanged and respective numerical order, multipliers, and points. Use different sheets for each band worked. Include a separate summary sheet showing name(s) of operator(s), callsign, and address. Each participant must include $2.00 US or IRC equivalent with their logs. Entries must be postmarked no later than August 15 for SSB and September 15 for CW and should be addressed to: RCV, PO Box 2285, Caracas 1010-A, Venezuela.

INTERNATIONAL WORLDWIDE DX SSTV CONTEST
Starts: 0000 GMT July 13
Ends: 2400 GMT July 15

Official rules were not received prior to press time, so I assume there are no major changes from last year.

This is the third annual DX SSTV contest sponsored by *A5 ATV Magazine*. This is a 48-hour SSTV video contest using 80 through 10 meters within the recommended SSTV calling/operating frequencies listed below. To encourage allband contest usage and promotion, extra bonus points are granted on the 10-, 15-, 40-, and 80-meter band segments. Single-and multi-operator stations are recognized, with crossband contacts not permitted. Individual contacts count only once per band with repetitive multiband contacts acceptable.

Callsigns and video reports must be in "video" form. Mug shots of the station operator, family, or friends can count only once. Slower clock-rate speeds are encouraged in either 128 16.5-second or 256 31-second timebases. Color work must contain a minimum of a 2-color overlay to qualify with standard RGB frame transmissions. Motion SSTV must have a minimum of 2 frames sent with automatic-receive switching circuitry or manually-operated switching by the receiving operator and 64 × 64 "quadrant" storage of no less than 4 separate pictures with replays.

SCORING:

Each SSTV two-way contact is worth 5 points within the same country and worth 10 points for DX out of country. Contact bonus points are available as follows: mug shots—1 point, slow speed—2 points, quad frame—3 points, motion SSTV—4 points, high resolution—5 points, and color SSTV (RGB)—10 points.

A band multiplier of 3 can be claimed for contacts on 40 and 80 meters, 2 for contacts on 6, 10, and 15 meters. Stations with over 25 DX countries worked add 25 points, with 50 DX countries add 50 points, and with over 100 DX countries add 100 points!

FREQUENCIES:

Advanced/Extra—3835, 7220, 14230, 21340, 28660, 50.150.

General—3990, 7290, 14340, 21440, 28680, 50.150.

AWARDS:

First-place winner receives a 3-year subscription (worth $60.00) to *A5 ATV Magazine* with front-cover picture plus a Gold Certificate. Second- and third-place winners receive one-year subscriptions and Gold Certificates. All entries regardless of score receive Gold Certificates suitable for framing. Results will be in the November issue of *A5 ATV Magazine*.

ENTRIES:

Submission of logs and totaled scores must be postmarked no later than August 1 and submitted to: Contest Manager, *A5, ATV Magazine*, PO Box H, Lowden, Iowa 52255-0408. Logs will be returned as will any photos, etc.

IARU RADIOSPORT CHAMPIONSHIP
Starts: 0000 GMT July 14
Ends: 2400 GMT July 15

This contest is open to all licensed amateurs worldwide and several changes have been made since last year. The object is to contact as many other amateurs in as many parts of the world as possible using 1.8 through 148 MHz. Single-operator stations must not operate more than 36 hours of the contest period. Operating categories include:

(a) Single operator: phone-only, CW-only, and mixed-mode sections. One person performs all operating and logging functions. Use of spotting nets is prohibited. Off times must be 30 minutes minimum and single-operator stations are allowed only one transmitted signal at any given time.

(b) Multi-operator: single transmitter, mixed mode only. Only one transmitted signal allowed at any given time and must remain on a band at least 10 minutes at a time. All operators must observe the limits of their operator's license at all times.

Stations may be worked once per frequency band; crossmode, crossband, and repeater QSOs do not count.

EXCHANGE:

Signal report and ITU zone.

SCORING:

Count 1 point per QSO within your ITU zone, 3 points within your continent but different ITU zone, and five points with different continents. Multipliers are the number of ITU zones worked on each band. Final score is total number of QSO points multiplied by the sum of ITU zones worked on each band.

ENTRIES:

All entrants are encouraged to use forms available from IARU/ARRL Headquarters; send SASE or 1 IRC. Logs must indicate times in GMT, bands, calls, and complete exchange. Multipliers and off-times should be clearly marked in the

RALEIGH AMATEUR RADIO SOCIETY
RARS
WORLDWIDE FRIENDSHIP

EXCITER

NEWSLETTER OF THE MONTH

This month's winner, *The RARS EXCITER*, is edited by Ann Bradley WA4APK (ably assisted in May by Murray Hake W6MVZ). Packed with information of all sorts, it's another great example of excellence in ham radio journalism.

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

logs. Cross-check sheets are required if more than 500 QSOs total are made. Entries must be postmarked by August 15; any entry received after mid-October may not be in time to be included in the printed results. Usual conditions of entry and disqualification apply. Entries should be addressed to ARRL Headquarters in Newington, Connecticut.

AWARDS:

A certificate will be awarded to the high-scoring CW-only, phone-only, mixed-mode, and multi-operator entrant in each ARRL section, each ITU zone, and each DXCC country. In addition, achievement-level awards will be issued to those making at least 250 QSOs or having a multiplier total of 50 or more. Additional awards may be made at the discretion of each country's IARU society.

SEANET WORLDWIDE DX CONTEST

CW

Starts: 0001Z Saturday, July 21
Ends: 2359 Sunday, July 22

Phone

Starts: 0001Z Saturday, Aug 18
Ends: 2359 Sunday, Aug 19

Use 160- through 10-meter bands. Entry classifications include (1) single-band, single-operator; (2) multiband, single-operator; (3) multiband, multi-operator. Power input is as stipulated in the regulations governing the licenses of the operator. The contest call is "CQ SEA" for the CW contest and "CQ SEATEST" for the phone contest.

EXCHANGE:

RS/RST report plus serial numbers starting with 001 and increased by one for each successive contact. See also Rule 3(d).

SCORING:

1) For stations outside the SEANET area:

(a) Contact with stations within the SEANET area of the following prefixes (DU, HS, YB, 9M2, 9M6, 9M8, 9V1, V85)—20 points on 160 meters, 10 points on 80 and 40 meters, and 4 points on 20, 15, and 10 meters.

(b) Contacts with other stations within the SEANET area not listed above in 1(a)—10 points on 160 meters, 5 points on 80 and 40 meters, and 2 points on 20, 15, and 10 meters.

(c) Contact between stations outside SEANET area will not be counted.

(d) Multipliers will be 3 points for each country worked, i.e., for countries between SEANET areas only.

2) For stations in the SEANET areas:

(a) Contacts with stations outside SEANET areas—10 points on 160 meters, 5 points on 80 and 40 meters, and 2 points on 20, 15, and 10 meters.

(b) Contacts between stations within the SEANET areas—6 points on 160 meters, 3 points on 80 and 40 meters, and 2 points on 20, 15, and 10 meters.

(c) Contacts between stations in own country will not be counted.

(d) Multipliers—contacts with countries within the SEANET area count 3 points for each country worked.

3) The final score will be the sum of the *points* multiplied by the sum of the *country multipliers*.

The list of SEANET area prefixes is as follows: A4, A5, A6, A9, AP, BV, CR9, C21, DU, EP, HL, HS, H44, JA/JE/JF/JG/JH/JI/JR, etc., JD1, JY, KA, KC6, KG6/KH2, KH6, KX6, P29, S79, VK, VQ9, V85, VS6, VS9K, VU2, XU, XV5, XWB, YB, YJ8, ZK, ZL, 3B6/7, 3B8, 3D2, 4S7, 4X, 5W1, 5Z4, 8Q7, 9K2, 9M2, 9M6/8, 9N1, and 9V1.

Some restrictions apply, as follows:

(a) Contacts on cross-modes or cross-bands or mixed CW/phone logs will be disqualified.

(b) Operators are not allowed to transmit two or more signals at the same time.

(c) Only one contact per band with the same station will be counted.

(d) Contest numbers should begin with 001 on each different band.

(e) All entries in violation of the contest rules, incorrect statements in the submitted reports, taking points from duplicate contacts, and practices against the brotherhood of amateur radio will be disqualified.

(f) The decision of the SEANET Contest Committee shall be final.

ENTRIES, LOGS, AND SUMMARY SHEETS:

All entries must be in the form of logs and summary sheets. All time must be in GMT. Entries must be received by the Contest Manager, Eshee Razak 9M2FK, PO Box 13, Penang, Malaysia, not later than October 31, 1984. Results will be announced at the SEANET Convention. If you require the results to be sent to you, please enclose IRCs together with your entry.

CW COUNTY HUNTERS CONTEST

Starts: 0000 GMT July 28
Ends: 0200 GMT July 30

The CW County Hunters Net invites all amateurs to participate in this year's contest. All mobile and portable operation in less active counties is welcomed and encouraged. Stations may be worked once on each band and again if the station has changed counties. Portable or mobile stations changing counties during the contest may repeat contacts for QSO points.

EXCHANGE:

QSO number; category (P for portable, M for mobile); RST; state, province, or country; and US county. Stations on county lines give and receive only one QSO number, but each county is valid for a multiplier.

FREQUENCIES:

3575, 7055, 14065, 21065, 28065. It is strongly requested that only P or M category stations call CQ or QRZ on 40 meters below 7055 and on 20 meters below 14065 with all other stations spreading out above those frequencies.

SCORING:

QSOs with fixed stations are 1 point; QSOs with portable or mobile stations are 3 points. Multiply the number of QSO points times the number of US counties worked. Independent cities may be counted as any one of their adjoining counties in accordance with USACA rules. Mobiles and portables calculate their score on the basis of total contacts within a state for state certificate and calculate their scores on all operations if they operated from more than one state in competition for the High Portable or High Mobile Trophy.

AWARDS:

Certificates will be awarded in three categories:

1) Highest fixed or fixed portable station in each state, province, and country with 1,000 or more points.

2) Highest station in each state operating portable from a county which is not his normal point of operation with 1,000 or more points.

3) Highest station in each state operating mobile from 3 or more counties with a minimum of 10 QSOs in at least each of 3 counties.

Plaques will be awarded to the highest mobile and portable stations in the USA that meet the above requirements for certificates. Additional awards will be issued where deemed appropriate.

ENTRIES:

Logs must show category, date/time in GMT, station worked, band, exchanges, QSO points, location, and claimed score. All entries with 100 or more QSOs *must include a check sheet of counties worked or be disqualified from receiving awards.* Enclose a large SASE if results are desired. Logs must be postmarked by September 1 and sent to: CW County Hunters Net, c/o Jerry Burkhead N6QA, 7525 Baltic St., San Diego, California 92111.

*****

I recently received a letter from the Yukon Amateur Radio Association concerning VY1 participation in future contests. As a result of a recent group meeting, they are requesting separate multiplier status for the Yukon Territory, VY1, for the following reasons:

1) In most contests, Yukon and Northwest Territories are classed as one. The Yukon has no ties with VE8, political or otherwise. The VY1 prefix has been in existence for 6 years now, although most publications still think they are either South America or Sable Island.

2) It is discouraging to have many VE and W amateurs call and have no idea where the VY1 station is located, especially since most contest information still lists them as VE8.

3) There are no super stations in the Yukon. With the propagation anomalies they suffer at that latitude, they cannot compete with southern stations. They are relegated to just being on during the contest period for the sake of giving out the prefix.

4) They have made an effort to have at least 3 stations on in every major contest for the past 2 years. The main participants have just had about enough and are seriously considering following their preferred methods of operating rather than spending complete weekends operating contests without any hope of turning in reasonable scores.

I think the letter speaks for itself and future contest chairmen may want to reconsider their multipliers!

NEW PRODUCTS

AMATEUR RTTY/ASCII/CW TERMINAL

ColoRadio Research, based in Loveland, Colorado, has announced the Model 900B Advanced Keyboard, a totally expandable amateur-radio RTTY/ASCII/CW terminal. It can be interfaced to a variety of computers via its RS-232C port and can be expanded to include a high-quality built-in keyboard, 16-character LED display, and/or 80-character-by-25-line high-resolution video interface.

The unit sends and receives Baudot and ASCII codes at all standard baud rates from 45 to 110 and can transmit at up to 1200 baud. The RS-232C port can handle up to 9600 baud with CTS/RTS, Xon/Xoff, or no handshaking.

The Model 900B also has CW transmit and receive capability. The ColoRadio Surecopy I algorithm automatically adjusts to any incoming speed within a few letters and the hardware and software signal processing minimizes garbled copy under even the worst band conditions.

Other functions include dupe-checking of up to 1280 calls, and touchtone™ and two-tone transmitter testing. The output *and* input tone frequencies can be changed at any time in 1-Hz steps, giving compatibility with not only current shifts of 170, 425, and 850 Hz, but also modem shifts of 200 Hz and any future shifts that may be used.

The unit interfaces easily with any amateur-radio station, with connectors for audio input and output, FSK, loop, autostart, key in, positive and negative key outputs, and video. A unique feature is the ability to multiplex the station microphone through the Model 900B to avoid having to switch cables when going from RTTY to SSB (useful on older transceivers that don't have separate mike and AFSK jacks).

Standard features include an 800-character type-ahead transmit buffer with break capability and buffer recall "pointers" that give an effective transmit-buffer capacity of 64,000 characters, ten 80-character message buffers, an 80-character WRU buffer, CW ID capability, 10,000-character receive buffer with scrolling, split- and full-screen display, complete status indications showing date/time, word mode, brag-tape status, diddle, sidetone, column number of automatic carriage return/line feed, operating mode, speed, tuning indicator, USOS, polarity, and frequency of transmit and receive tones. The dupe-check function has nicad battery backup to allow the user to return home from field contests and dump the stored calls to a computer or printer.

Inquiries should be mailed to *ColoRadio Research, PO Box 603, Loveland CO 80539; (303)-667-7382*. Reader Service number 477.

MICROCOMPUTER LOGGING PROGRAM

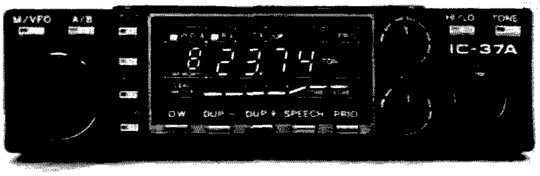
Crumtronics has announced Contender, a logging program for the Commodore 64 microcomputer.

On a single-sided disk you can enter 2,000 entries, allowing callsign, RST sent/received, time/date (auto or manual), name, QTH, zone, and QSL information for each entry. Contender permits forward/reverse scan, has an edit/update feature, and allows you to PRINT: dupe sheet to printer or screen, QSL labels, QSL cards, and complete log.

Contender is being expanded to include allband WAS, WAZ, DXCC, and state/county report. The expanded version will be known as Contender Plus and will be priced slightly higher.

For more information, write to *Crumtronics, Software Division, PO Box 6187, Fort Wayne IN 46896; (219)-745-0350*. Reader Service number 481.

IC-37A 220-MHZ MOBILE



IC-37A mobile transceiver.

Icom has announced the IC-37A 220-MHz compact mobile transceiver. The IC-37A features:

- 25 Watts/5 Watts low
- same design as IC-27A—5½" W × 1½" H × 7" D
- 32 PL frequencies—standard, built-in
- 9 memories with offset and PL storage
- dial steps: 10 kHz/5 kHz
- memory scan, band scan, and priority scan
- dual vfo's
- HM-23 touchtone™ and scanning mike standard
- speech-synthesizer option
- Nor/Rev switch

For more information, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue WA 98004; (206)-454-8155*.

60-MHZ SCOPE FROM KIKUSUI

A new 60-MHz oscilloscope, featuring peak-to-peak automatic triggering and automatic focus was recently added to Kikusui's line of oscilloscopes.

Other key features of the scope, model 5060, include delay sweep, delay line, alternate sweep, a third channel signal, and a vertical-signal output on the back of the unit. Sensitivity is 1 mV with 5× magnification. The scope also includes a sync separator as standard.

In addition, a variable hold-off allows precise adjustment of trigger hold-off time, ensuring stable triggering on complex or long waveforms. Auto triggering and peak-to-peak auto triggering, on the other hand, ensure stable triggering at all input amplitudes. The built-in delay line allows accurate leading-edge measurements. Also, a two-channel X-Y operation is included.

The CRT of the 5060 is a 6" rectangular with 12 kV of accelerating potential to provide a clear, bright display, and automatic focus even when intensity is adjusted or the sweep rate is changed.

The unit is small, measuring 6.9" H × 11" W × 14.6" D. It weighs just under 16 pounds.

Ac voltage is selectable: 100, 115, 215, or 230 V, 50 or 60 Hz. Power requirements are approximately 40 VA.

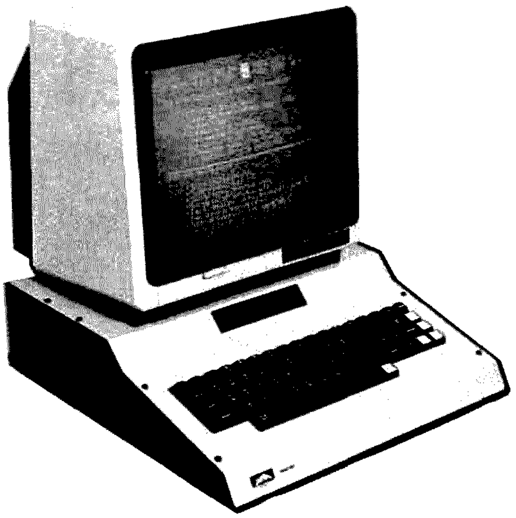
Applications for the 5060 include computer field servicing, industrial control, process control (e.g., the paper industry), food processing, and assembly lines.

"It fits two niches nicely," explained Bill White, vice-president of marketing for Kikusui. "One is field service where light weight is a prime consideration, and the other is production lines where KIK's automatic triggering simplifies and speeds operation."

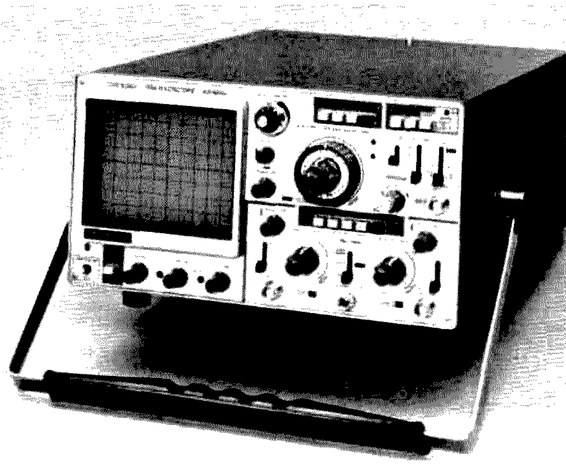
For more information, contact *Kikusui International Corporation, 17819 S. Figueroa St., Gardena CA 90248; (800)-421-5334*. In Alaska, California, and Hawaii, call *(213)-515-6432*. Reader Service number 476.

CONFINED E-FIELD DISPLACEMENT ANTENNA

Moler Antenna has produced a 16-foot, 80-meter vertical that enables any radio amateur to operate with a big signal from a small lot. It is motor-tuned at the loading coil to cover the whole band from 3.5 to 4.0 MHz. Fed with 50-Ohm coax, it handles the legal limit plus some and can be ground- or roof-mounted. The antenna is top-loaded with both inductance and a top capacity hat. The loading coil is wound with 3/8-inch-wide copper strap and the capacity hat has a diameter of approximately 8 feet. When ground mounting, a radial system of approximately 32 wires, about 25 feet long, is recommended. For mounting above the ground, at least 8 radials about 25 feet long, are recommended. The antenna requires 3 guy ropes. The assembly time is about 30 minutes. The loading coil motor is a 12-volt-dc reversible motor and can be driven easily by a 9-volt tran-



RTTY/ASCII/CW terminal from ColoRadio Research.



60-MHz oscilloscope from Kikusui.

sistor-radio battery. You can build your own control box or buy one from Moler. This antenna has a low wave angle, therefore, it works very well on DX. Two or more of these antennas can be phased easily by driving only one and using the others as parasitic elements, steering the beam in any direction by remotely tuning the mutually coupled antennas.

A conversion kit is available for the above antenna. It converts the 80-meter vertical to half-wave vertical. The conversion kit eliminates the need for radials and increases the height of the antenna by 3 feet (making the overall length approximately 19 feet). For more information, contact *Moler Antenna Corp., 2623 Morris Lane, Girard OH 44420; (216)-530-2059.*

HF ANTENNA DESIGN PROGRAM

HF Antenna Design is the latest offering in Cynwyn's software series for amateur-radio hobbyists. The program makes the necessary calculations for building three popular types of antennas—dipole, yagi, and quad—for frequencies of 1.8–30 MHz and displays them in an easy-to-read tabular format. Dimensions for the yagi and quad are optimized for maximum gain.

HF Antenna Design requires a TRS-80C Color Computer with 16K RAM and Extended Color Basic or an MC-10 with 4K RAM.

For more information, contact B. E. Wynkoop at *Cynwyn, 4791 Broadway, Suite 2F, New York NY 10034; (212)-567-8493.* Reader Service number 479.

NCG'S NEW TRIBANDER

The new tribander, 40–15 plus 6 meters, will give all amateurs, from Novice to Extra, a rig that will fill the gap. The 7-21-6M is all solid state with built-in ac/dc; no external power supply is needed. Full band coverage on 40 and 15 meters with 6-meter coverage from 50.0 to 50.50 MHz. All bands operate in the modes of SSB or CW. Drift-free operation is less than 100 Hz. Two antenna connectors allow bandswitching easily, one is for 6 meters and the other is for 15 and 40 meters. Transmitting final stage is 26 Watts PEP and modulation is a balanced type. Carrier suppression is more than 40 dB down. Microphone impedance is from 50 to 400 Ohms. With built-in TVI suppression for 6 meters, this tribander will be a pleasure to operate. With a slow swr on the 6-meter antenna, no or very little TV interference will be encountered. The 7-21-6M is an ideal transceiver for the Technician, phone on 6, and CW on 15 and 40 meters. The tribander is small enough to operate mobile and large enough for a base rig. The tribander should be available in July. For additional information, contact *NCG Co., 1275 N. Grove St., Anaheim CA 92806; (714)-630-4541.* Reader Service number 478.

SHACKMASTER

Advanced Computer Controls, Inc., has introduced ShackMaster, a new product which allows you to remotely control your shack and effectively communicate with family members over *your* home equipment.

ShackMaster's crossband linking capability allows you to access your high-performance home station from VHF/UHF, either simplex or through repeaters. Telephone access permits remote control of your home station from any touchtone™ telephone. BSR X-10 shack control offers touchtone remote control of 120-volt devices with touchtone commands, over the air or over the phone.

ShackPatch, a remotely controlled intercom into the home, permits you to remotely control your home equipment, allowing third parties to participate. ShackPatch is based on the same principles as an autopatch, and you are in complete control of your station at all times. An electronic mailbox permits you and your family to leave messages for each other, to be retrieved when convenient. Finally, a simplex autopatch is available when it's necessary to make a phone call, report an accident, or call a friend.

ShackMaster is based on ACC's proven repeater control technology. It includes electronic synthesized speech with a custom vocabulary. It interfaces to up to three transceivers, the phone line, and a local speaker and microphone.

For more information, contact *Advanced Computer Controls, Inc., 10816 Northridge Square, Cupertino CA 95014; (408)-749-8330.* Reader Service number 480.

ShackMaster from ACC.

MODEL CS-16 TOUCHTONE DECODER

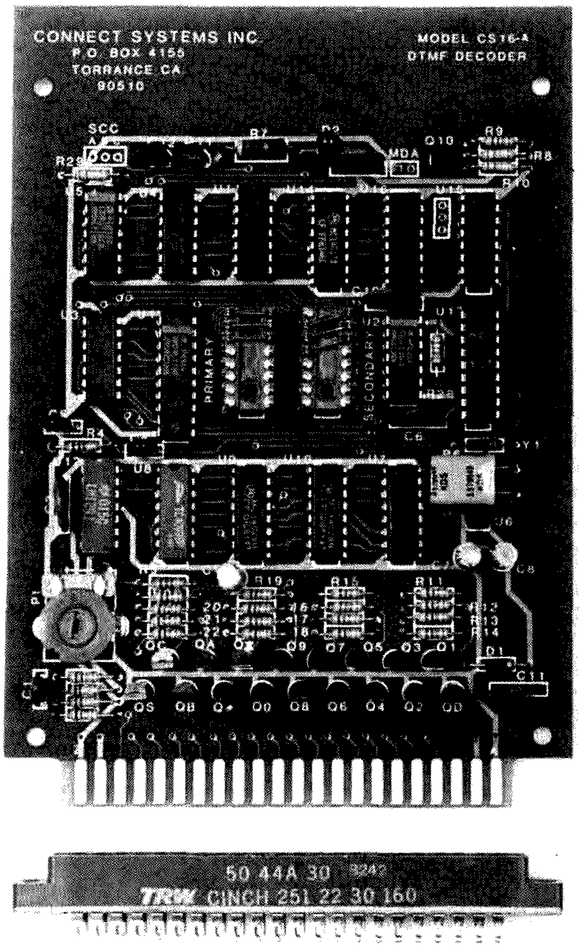
Connect Systems, Inc., has introduced a low-cost, 16-function touchtone™ decoder board. Designated as model CS-16, the decoder will securely control virtually any apparatus via radio or wire. The CS-16 is especially useful for controlling various repeater on/off functions.

One feature of the CS-16 is dual password control. Two separately user-programmable three-digit passwords create heirarchy control capability. The primary control password can access all 16 of the available functions. The secondary password, however, can access only 8 of the 16 functions. Additionally, a special primary password command is available which can enable or disable secondary password access. The CS-16 provides such a high degree of multi-level security that control can be accomplished directly on voice channels thus eliminating the need for separate control frequencies.

The CS-16 provides 16 independently controllable on/off latched functions. Each function is provided with an open collector and a 5-V CMOS logic output. A strobe output is also made available in open collector and logic format. This output can be used to gate repeated audio so that DTMF control commands are not retransmitted—a further security enhancement.

A power-up reset feature causes all outputs to be in the off state after application of power. An audio preamp with level control permits the crystal-controlled tone decoder to operate over the wide input range of 10 mV to 2 volts. A strobe LED lights when any of the 16 buttons on a pad is pressed. (The CS-16 can also be used with 12-button pads.) An on-board voltage regulator permits operation with a 10–25-V-dc power source. The CS-16 incorporates reverse polarity protection and draws less than 20 mA from the supply.

The CS-16 is constructed on a top-quality glass board with plated-through holes. The board is reflow-soldered and machine-trimmed. The 44-pin edge connector is gold plated for extreme reliability. The CS-16 is supplied with mating connector, manual, and limited six-month warranty. For more information, contact *Connect Systems, Inc., 23731 Madison St., Torrance CA 90505.*



New touchtone decoder from Connect Systems.

NCG's new tribander.

REVIEW

THE SUPER SANTECS—EVEN BETTER NOW

In last October's issue of *73*, I reviewed the Santec ST-/uP series of handie-talkies in glowing terms. Since then the importer, Encomm Inc., has introduced substantially updated versions of all three radios. The ST-144/uP, ST-220/uP, and ST-440/uP have been replaced by the ST-142, ST-222, and ST-442.

The good news is that, good as the earlier versions were, the new ones are better. The really good news is that Encomm hasn't forgotten all you buyers of ST-/uP radios: For a cost considerably less than that of a new radio, they will update your ST-/uP into the new model, as they have done for all three of mine. I can't remember any manufacturer/importer having done that before.

The changes in the new models affect the microprocessor operating system. The transmitter and receiver are unchanged, and both have the excellent specs that were published in my October review.

Programmable Offset

What's different? A whole lot. First and foremost, the transmit offset is now separately programmable on all ten channels! Think about that. If you use odd-split repeaters, or if you want to listen on your repeater's output but transmit on a control frequency, you can set up a channel memory for that purpose. In the ST-/uP radios, you could set up one, and only one, "special" offset, by receiving on the set frequency and transmitting on the frequency stored in memory 1. Now you can have a different offset in every memory channel if you want it! You can also use the variable offset feature in the "normal," i.e., non-memory, mode, and it will apply to whatever receive frequency you program in.

The offset is variable in 10-kHz steps (25 kHz on the ST-442), the maximum offset is 9990 kHz (9975 kHz on the 442), and the minimum offset is twice the minimum adjacent channel step (meaning 10 kHz minimum offset on the VHF radios and 50 kHz on the UHF one). Bear in mind that if your offset results in an out-of-band transmit frequency, nothing will happen when you press the push-to-talk bar.

If all this versatility isn't enough for you, as might happen if you wanted an offset not divisible by 10 kHz, the "old" setup of receiving on a selected channel and transmitting on a frequency stored in a "special" memory is still available. Memory 9 has replaced memory 1 for this purpose.

Programmable CTCSS

Still on the subject of "customized" channels, Encomm is offering a programmable CTCSS encoder for the new radios that will allow you to generate a different subaudible access tone on each of the memory channels. The encoder uses a PROM that you customize yourself. If you buy this accessory, you also get a little programming board which takes the PROM and uses any 12-V-dc source to program it as you desire. Then all you have to do is select the channel you want, and the correct transmit offset and subaudible tone frequency are right there automatically.

Status Memory

Variable offset and custom access tones are just the beginning. When you turned the ST-/uP radios off and then on again, they "woke up" on whatever frequency was stored in memory 1, but in "normal" (i.e., not memory) mode. This meant that when you finished a QSO and shut down the radio, then remembered you had something else to say, you would have to reselect the channel on which you had been talking (unless it happened to be the one in the first memory). No more! The new Santecs "wake up" in *exactly* the status they were in when you shut down—on the same memory channel or on the same normal mode frequency, whichever way you had it set up when you switched off. Incidentally, this eliminated the "bug" mentioned in last October's review, which related to use of the clock (yes, the clock is still there). Sometimes when I switched to the clock mode and back to the frequency display, I found the radio on the memory 1 frequency in normal mode, as though I'd shut off the power and turned it on again. That no longer happens, because interrupting the power doesn't affect the frequency/memory settings.

Scan Lockout

We're still not finished with the goodies list. On the ST-/uP radios, you could scan all or a set part of a band or you could scan the ten memories, with a priority feature for the memory 1 frequency. If you were scanning memory channels, you had to scan all ten, and the radio would stop on each one that was active. This meant that if you had programmed in, say, your three favorite repeaters, and six or seven more that you used only occasionally but wanted to have available, the radio would stop scanning on the less-interesting channels if they were in use, which introduced some delay in getting to the stuff you really wanted to hear.

Problem solved. The new radios have a "lockout" feature which can be applied to any channel. Select that channel, turn the "memory write" switch on, and press the "B" key. A small "L" lights up next to the frequency display, and that channel is locked out of the scan until you cancel the lockout. The locked-out channel is still available by keyboard selection, of course—it just won't show up in scan mode.

New "Open"ing

Speaking of scanning: Have you ever made use of an "open" scan feature which lets you scan for a quiet channel? In theory it's a nice idea, but in a country with a lot of repeaters, it isn't too useful. I can't ever recall using it, although all three of my ST-/uP radios had it.

Well, I'm going to start using "open" scan now, because on the new Santec radios it isn't what it used to be. First, a quick refresher course in Santec scanning is in order. You had (and still have on the new radios): "MAN"ual scanning, one frequency step for each press of the "up" or "down" keys, continuous if you hold either key for a second or so; "SCAN," stop on each busy channel, auto restart after 6 seconds or so; and "SRCH," stop on a busy channel, no auto restart. The new "OPEN" mode stops on each busy channel, but auto restart is delayed until the channel has been quiet for a few seconds. Using "OPEN," you can hear a QSO out to its finish, and then the radio will resume scanning. That's a useful feature, and to my mind much more so than the ability to scan for a quiet channel. Remember also that all the Santec radios have variable scan interval—5 to 100 kHz for the VHF units, 25 to 100 kHz for the ST-442.

Accident Prevention

On the ST-/uP radios, some care had to be exercised when programming memories. You set up the receive frequency on the display, set the offset switches the way you wanted, turned on the "memory write" switch, pushed the "write" key, and entered the desired channel digit. The problem was, if you accidentally pressed a second digit before turning off the write switch or pressing the write key a second time, the same frequency got written into another memory. Several times I forgot this, went into the "memory write" mode, and then entered the frequency I wanted. If I entered "673" (for 146.730 MHz), I got whatever frequency was on the display entered into channels 3, 6, and 7—overwriting anything that had been there before!

The new radios eliminate this problem. The act of storing a frequency in a memory channel automatically takes the microprocessor out of the write mode. The worst that can happen is that you get one wrong frequency stored, not three or four. A big improvement.

The new radios are identical in their external details to the earlier versions. The only obvious difference is the nameplate, which carries the new model number.

Updating Available

I said earlier that Encomm will update your ST-/uP radios. At his writing, the updating charge is $100—a lot less than the cost of a new radio. Your updated version will be identical in all respects to the new models and will accept the accessory programmable tone encoder. So you can have your ST-/uP made over into "this year's" radio instead of trading in the old one. Encomm hasn't abandoned you.

If you liked the ST-144/uP and its cousins, you'll love the ST-142.

For further information, contact *Encomm, Inc., 2000 Avenue G, Suite 800, Plano TX 75074; (214)-423-0024*. Reader Service number 482.

WHAT DO YOU THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

ICOM'S IC-RP3010 70-CM REPEATER

In our efforts to escape from the crowded metropolitan-area 2-meter band, our club sought refuge on 440 megahertz. Such a move in a heavily populated area is fraught with its own perils. Our repeater site on top of a high-rise apartment building provides excellent coverage, but many of the commercial operators in the area have had similar feelings and installed (more than 20) commercial repeaters within several hundred feet of our site.

It was a difficult decision to select a repeater that would be cost-effective and yet sufficiently selective to be able to cut the mustard. A modern commercial repeater was out of the question because of cost, and the older commercial variety used by many of the other 440 groups in our area required PL™ to keep the intermod out.

The Icom IC-RP3010 seemed a likely candidate; however, we had difficulty obtaining any information on it. We finally decided that the Icom name and reputation was enough to go on and after some difficulty locating one in this country and arranging for its shipment, we were pleasantly surprised when we opened our new package.

The repeater cabinet is constructed of heavy-gauge metal and is completely shielded on both top and bottom. Both the transmitter and the receiver are mounted in rf-tight boxes with quick disconnect plugs to enable easy removal for service. The power supply has a trickle charger to keep a backup battery fully charged for emergency power, and the power-on light, normally green for ac operation, changes to red to warn of battery power. A large heat sink the entire width of the cabinet is installed on the rear to dissipate heat generated by the power supply and PA.

The controller, CTCSS, and touchtone™ decoder boards are mounted underneath the main chassis. The front panel of the repeater is anodized aluminum, very attractively finished with an easy-to-follow block diagram of the repeater controls embossed on its face. Volume and squelch, CTCSS on-off, transmitter inhibit, manual ID, and COR simulate are the only external controls on the repeater. Annunciator lights make it easy to determine the mode and status of the repeater. It is 19" rack width, but the mounting holes are metric and may not line up with all US racks (possibly requiring rack modification by drilling new holes).

We bought the repeater with the optional Icom mounting rack which allows approximately 12" below the repeater for mounting duplexers or other accessories. It makes the repeater very attractive; thus far my wife has not objected to its being in our apartment, where it serves as a table.

The repeater comes from the factory aligned on a Japanese repeater frequency in the 430-megahertz portion of the band, so our first step was to install the crystals we had previously ordered for our assigned frequency and then retune the transmitter and receiver. The Icom manual contains detailed instructions on all alignment procedures. However, as in most manuals translated from the Japanese by non-native-English-speaking writers, some of the instructions require a little careful thought before execution. The receiver and transmitter both tweaked up well within Icom specs. Squelch on the receiver opened at 0.1 microvolts, and the transmitter produced 14 Watts.

The control board "brain" is a factory-programmed EPROM which contains the settings for all the timers with the exception of the squelch tail and the repeater callsign. The EPROM must be returned to Icom to have the repeater callsign programmed in ROM. Perhaps Icom could make some arrangement to program the EPROM and tune the transmitter and receiver on the user's frequencies at the

factory before shipment so that the entire repeater would become a turn-key operation.

The machine is now up and running and producing excellent results. We are running it without a power amplifier, using Wacom WP-678 cavities, and are currently using about 115 feet of hardliner. The results have been excellent. The audio is typical Icom and is equal to or better than that of other repeaters. Intermod has not been a major problem and we have been able to operate with the CTCSS off with little intermod interference.

The CTCSS frequency tolerance seems rather broad, and mobile stations have been able to get in even if they were one or two codes away from ours.

The repeater comes with single-digit touchtone™ control for repeater and CTCSS on-off, and we have found that the decoder frequently falses on voice modulation, thus turning the repeater or the PL™ on and off at inconvenient times. The single-digit decoder can be defeated by inserting an included jack on the rear repeater panel or by installing the IC-EX339 3-digit decoder available as an option from Icom.

Unfortunately, no provisions for installing an autopatch have been included. However, interfacing any commercial autopatch should be a rather easy job.

In summary, I feel the IC-RP3010 is an excellent piece of equipment well worth its purchase price. As soon as more become available, it is going to make the 440-megahertz band a popular place.

For further information, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue WA 98004; (206)-454-8155.*

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

As I write this column, this year's Greater Baltimore Hamboree and Computerfest has come to a close. It is amazing to describe the changes that have become apparent within amateur radio over the past several years, as viewed from the perspective of a hamfest.

Not that long ago, the bulk of dealers at these gatherings were selling big boxy transmitters or receivers, or tubes or other parts by the bin. As far as RTTY went, you could usually find a Teletype® Model 15 or two, or maybe a Model 28 if you were lucky, but not much else of especial interest to the RTTYer.

With the coming age of digital communications, all this has changed! This year, I would estimate the average distance between keyboards as under three feet, and that is allowing for the still considerable number of non-RTTY or computer items being displayed. Walking around this giant hamfest (which takes over the Timonium Fairgrounds, home of our Maryland State Fair, every spring) and pushing through the thousands of folks who braved a cold rainy day to come pointed up many sights.

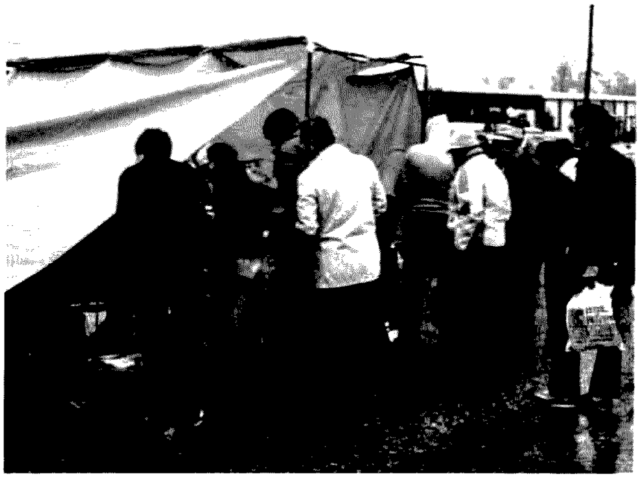
I found RTTY bargains aplenty, ranging from rolls of paper at giveaway prices to one gent offering a Teletype Model 33 for all of ten dollars. Computer manufacturers have not forgotten us either, folks. Just about every table had a computer set up to either run RTTY or serve some other useful function in a ham shack. Yes, RTTY is more alive than at any time in its history. Hmm, there is a topic for a future column—the history of RTTY!

At any rate, included in this month's column are a few choice photos taken at this year's hamfest.

At the risk of inundating Levittown with mail, I have a note here, the contents of which I must pass along. As of the date of this writing (the first week of April), Fred Weidenhammer W4SDL/2 indicates that he has a Teletype Model 35-RO, free to someone willing to pay shipping and insurance. This is a receive-only ASCII printer, and it does not have a cabinet. That is all I know. I would suggest you contact Fred for further details at 332 Blacksmith Road, Levittown, New York 11756.

More comments on the various programs to run RTTY on TRS-80 Models I and III have arrived. Bill Buckingham WA3LIL, who has written us before on the subject, passes along the information that the programs he uses operate through the I/O bus of these computers with an I/O interface. The Model I has a forty-pin bus and the Model III a fifty-pin bus, so there are a few differences between them, but apparently they are not insurmountable. Bill also indicates that work is under way to adapt these programs to the new TRS-80 Model 4. Thanks for the information, Bill.

Along the same line, regards to Richard Ellers K8JKL of Warren, Ohio. Richard is trying to put his TRS-80 Model III onto RTTY and is looking for software. I have put Richard in touch with Bill and hope to see him on RTTY very shortly.



The outside tailgating area, showing mostly the rain and tents.

Duane Vincent KA7JEX from Seattle, Washington, passes along his comments with regard to running a Texas Instruments TI-99/4A on RTTY. Using one of the popular interfaces available, Duane is very pleased with this setup. He notes that the keyboard touch on the 99/4A is not unlike that of the IBM terminal he uses at work.

Duane has also used a VIC-20 on RTTY. He uses that computer for portable RTTY out of his van. Boy, that brings back a picture in my mind of a vehicular station set up locally some years ago by W3DTN, complete with a mobile Model 15! Well, Duane prefers the 99/4A keyboard to the VIC, but he likes to run the VIC on the mobile 12-V-dc battery power. Yes, sir, things are moving along!

Another Commodore patron is Allen Fugelseth WB6RWU. Allen is using a Commodore 64 computer and is looking for, as he puts it, "free or inexpensive software." Well, I have not seen anything that quite meets that description, but I will keep my eye out. Part of the problem, Allen, is that I try not to recommend products that I have not seen or that I have not received other detailed information about from a source other than the manufacturer. There have been a few "lemons" dangled in there with the other fruits and such, and I would rather avoid them if I can. Will keep you and the rest of the fan club posted on new software as the information arrives.

New members of the CoCo club include Bruce T. Brackin of Oklahoma City, Oklahoma, and Peter G. Pototsky NH6BF of Kailua, Hawaii. Bruce is an SWL with an interest in putting his CoCo to work receiving the RTTY he hears on the air. I have forwarded the information covered in the last few months here to him to help in these efforts. Bruce asks if I have noted any computer-generated rf problems as-

One of the highlights of the hamfest was a look at the FCC mobile monitoring van.

One of the indoor flea-market areas at the Greater Baltimore Hamboree.

sociated with the CoCo. He notes that his "Osborne I will tear the National (NC-400 receiver) to pieces, and just about anything else within about 100 feet of it." Well, Bruce, I have not noticed any RFI at all with the CoCo, and I think that is a tribute to careful attention being paid to those design features which minimize "leaks." I don't know why your Osborne is causing problems; I have several friends who are using theirs without interference. Would suggest you check out your grounding in the station to be sure that a floating ground or the like is not the culprit. Who knows, you may hear enough RTTY to want to get a license and join us!

Peter, when he is not basking on the beaches in Hawaii (do you know how miserable the weather in Maryland is this time of year?), is trying to put his CoCo on RTTY and would like a disk-based program to do it. Well, at this time, I know of no disk-based program that exists. I have indicated to Clay Abrams that upgrading his excellent tape program would be ideal, and he has related the intention of doing just that, but these things take time. In the meantime, you might drop Clay a line at 1758 Comstock Lane, San Jose, California 95124. Tell him that WA3AJR said to bug him for a disk program!

Well, response to my offer for some basic RTTY material has been gratifying. Therefore, I am now preparing a second edition of RTTY material. This stuff was covered here several years ago and is being re-presented for those who came in late, forgot it, or whatever. Issue number one dealt with the basics of RTTY data exchange; number two shall deal with the essentials of the RTTY code structure, primarily Murray and ASCII. These are several pages of information, offered at a cost of $2.00 each. If you would like either of these editions, just drop me a line at the above address and include a self-addressed, stamped envelope and $2.00 for each issue desired. I will continue to put more of this information together as time permits and demand persists.

DXING IN JULY

July. The lazy, hazy, noisy days of summer. High absorption batters down the higher bands, while summer thunderstorms fill the lower bands with deafening static crashes. Even the usually productive sunrise and sunset operating times are short and dull. Let's face it: July is not the best month for DXing.

So what's the DXer to do for the month of July? Take a month off from DXing? Maybe get to know the family again, before the bands start to pick up again in the fall? If you do that, of course, they'll start to expect you around the house, and it will be even harder to lock yourself into the radio shack for the start of the next DX season.

Fortunately, there are plenty of DX-related activities well suited to the dog (if not Dog X-ray) days of summer.

Antennas

The first thing that comes to mind is antennas. July offers an excellent time to review your DX-antenna farm. What worked last season? Will that antenna be good enough for the next DX season? With the decline of radio propagation, you might consider improving your low-band aerial hardware; 40, 80, and 160 meters will be hopping the next few winters. Meanwhile, the DX pickings on 10 meters will be few and far between. Even 15 meters will provide but sporadic excitement for the mid-80s. So think low bands, long dipoles, inverted vees, zepps, verticals, and ground planes.

If you are fortunate enough to have sufficiently tall, properly-spaced trees on your property, July is a good month to break out the bow and arrow or fishing rod and stick up a few wires and strings. So what if the neighbors think you're a little soft in the head, fishing in trees. Murmur something about flying fish and air sharks; they all think you're crazy to be a DXer anyway.

What kinds of antennas should you get up for the low bands? The bigger the better, of course, and height helps too. Vertical antennas seem to work better on the lower bands, if you can provide a reasonable ground. (We'll talk more about the low bands and DX antennas in a future column. Meanwhile, watch for bargains in lots of wire, and try to figure out how you are going to squeeze a 160-meter dipole onto your city lot.)

Paperwork Is Never Finished

DXers whose antennas are already big enough (if any) and those whose financial, environmental, or family circumstances preclude better antennas, might make use of the month of July by catching up on their DX paperwork.

Review your DXCC totals, QSLs sent and received, and your "need" list. The new DXCC Countries List from the ARRL provides a good place to tally your present worked/confirmed totals. This multi-page pamphlet provides columns for all HF bands and for many of the other DXCC awards, such as RTTY bands and satellite. Three drawbacks with the new listing are: no spaces for new and changed countries within the listing, no place for band totals, and the cost—now $1.00 postpaid from ARRL.

Do you have any countries worked but not confirmed? Take some time in July to follow up those QSLs. If you wait too long to confirm after the contact, the chances of getting your card decrease. So, if you have cards outstanding to QSL managers and in other direct methods, see if a follow-up note might be in order. Of course, if you are awaiting cards via the QSL bureau, don't hold your breath; it might be years before you receive your cards.

If you do decide to send reminders or second requests for cards, check the current callbooks, QSL-manager lists, and DX bulletins for the most recent QSL information.

Two fortunate readers of the column can turn to their complimentary subscriptions to weekly DX bulletins (see this column, January, 1984). In the drawing held earlier this year, the awards and lucky readers were: *The DX Bulletin* (Box DX, Andover CT 06232) to John Holstead VS6HJ, and *QRZ DX* (Box 834072, Richardson TX 75083) to Ray Perkins KA2PSW.

Congratulations to both! And for the rest of you DXers who didn't win the free subscriptions, you can keep up with the day-to-day activities in the DX world by taking out your own subscription—see the address above. It's hard to have too much information in DX!

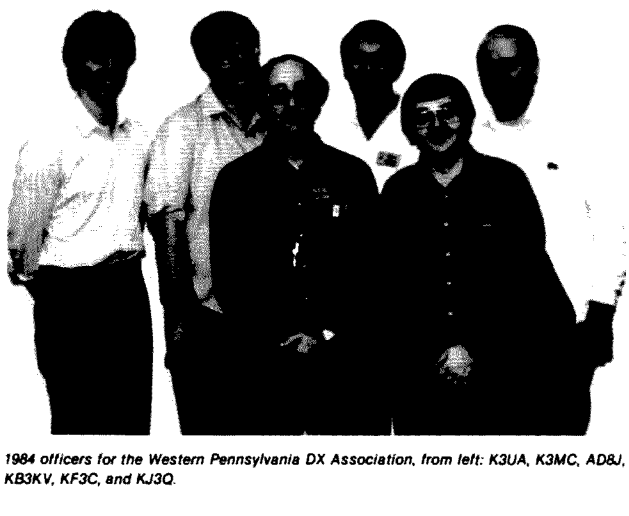
Another source of up-to-date DX information is your local DX radio club. Through meetings, newsletters, and DX-oriented repeaters, club members share ideas and locate the rare ones. And clubs provide assistance with Beam Teams and Quad Squads to repair damage from last winter's storms and put up even bigger aerial hardware.

These DX radio clubs depend on the interest, expertise, and enthusiasm of the members of the clubs. The club officers devote many hours of their time to provide programs, speakers, events, and camaraderie for the club. Too often when an officer asks for help with a club project, his efforts are rewarded with dead silence.

So, if you're not already a member of a local DX club, consider joining. If you are a member now, speak up the next time the club needs something done; help your fellow DXer. And if you already are active in your DX club, think about running for club office next time and share your energy to improve the DX world.

Among those who are doing just that are the officers of the very active Southeastern DX Club, centered in Atlanta, Georgia. Officers for 1984 include President Carl Hanson WB4ZNH, Vice-President Grover Meinert KC4BX, Treasurer Carol Shrader WI4K, Secretary Joel Levine WA4HNL, and Activities Chairman Jim Steible K4DLI.

The Western Pennsylvania DX Association's officers for 1984 are: President John Getz AD8J, Vice-President Phil Koch K3UA, Secretary Wayne Albert KB3KV, Treasurer Don McDanial KJ3Q, DX Information Chairman Denny Brantner KF3C, and (newsletter) Editor Mike Chepponis K3MC (see photo).



1984 officers for the Western Pennsylvania DX Association, from left: K3UA, K3MC, AD8J, KB3KV, KF3C, and KJ3Q.

Also on the east coast is the newly-founded Connecticut DX Association. That association's officers are: President Ron Richards WB1EAZ, Vice-President Paul Shafer KB1BE, and Secretary/Treasurer Tom Le Clerc WB1CBY.

And in the center of the country, the dynamic and interesting Kansas City DX Club sports the following for the 1984 slate of officers: President John Chass WØJLC, Vice-President Bill Henderson KØVBU, Treasurer Tom Bishop KØTLM, Secretary Steve Gecewicz KØCS, and (newsletter) Editor Mike Crabtree ABØX.

Congratulations to all these and other DX club officers. And for the rest of you: Isn't it time you did your part to make your DX club interesting and helpful?

Operating Events

No matter what other, nonoperating activities the DXer finds to while away the month of July, nothing provides quite the same satisfaction as getting on the air and working DX. Fortunately, despite the lousy band conditions, a couple of operating events help stir up the DXers in the heat of the summer.

The most popular on-the-air activity in July is the International Amateur Radio Union (IARU) Radiosport competition, the weekend of July 14-15, 1984. (See the "Contests" column in this issue, and see the rules in the May issue of *QST*.) Briefly, you try to work stations in different International Telecommunications Union (ITU) zones, *which are not the same* as the *CQ* magazine zones for their contest and awards program.

The Radiosport rules (assuming no major changes from previous years—check this) provide a heavy premium for working stations on different continents. In addition to the possible new zone multipliers of these stations, each contact with a station on a different continent counts five times as much as a contact within one's own zone. So the emphasis is on DX contacts.

The rule structure of this contest brings out many DX stations, anxious to fight the low Maximum Usable Frequency and high noise levels to work each other and maybe even you! The eastern Europeans and Russians are especially fond of this contest, and Radiosport provides an excellent opportunity to contact many of these stations.

The 1984 Radiosport contest will be quite different in at least one way: Many of the Russian stations will be sporting new callsigns, thanks to a major revision of the Russian callsign system this spring. All the radio club calls in the Soviet Union and many individual callsigns will be different. And unlike the FCC callsign "reform," in the USSR the callsign will give the location!

Here's how the system will work, with thanks to the *Murphy Message*, the newsletter of the Murphy's Marauders radio club:

The *first* letter of the callsign will be U or R. (Ten-meter fans are familiar with the low-power RA prefix stations from the USSR.) The *second* letter will indicate the republic: A for RSFSR, B for the Ukraine, etc. This is similar to the present system, but the procedure will be used for *all* calls in the republic, including club callsigns, which presently have a UK prefix. The number in the call will no longer be fixed, as now. If you hear UB, you won't be able automatically to add a 5. UB calls will be issued with any numeral, and the same with all the other republics, UI8, UL7, UF6, etc. The *third* letter (directly after the numeral) will help identify the oblast, or location. The *fourth* letter will be anything except W through Z, which are reserved for club stations. There might be a fifth letter in some areas. For example, UB3BDS would be a Ukrainian in the Ternopol oblast. Just to confuse things, some of the older two-letter suffix calls (issued before 1970) will stay the same.

In that part of the world, where amateurs must build their own gear and individual amateur licenses are relatively few and far between, the club stations account for much of the operating activity. In every contest, the big-gun clubs, such as UK2BBB, provide the little-gun DXers with their best shot at working the rarer Soviet republics. All these clubs now operate under new callsigns without the familiar UK prefix. Club stations will be identified by the last two letters of the callsign: WA through ZZ. So a club station in the Ternopol oblast might be UB8BZZ. (In RSFSR, UA1-4, 6, 9, and 0, club calls will have a UZ or RZ prefix.)

Bob Hess KA3EAL does his DXing from this compact station in Penns Creek, Pennsylvania.

Meanwhile, we hear that the French are jumping on the new callsign bandwagon. According to *Les Nouvelles DX*, the present F1 calls will change to FC1 and FD1. F2-F9 calls will emerge as FD2-9 and FE2-9. Corsica Island calls, now sporting an FC prefix, will be TK1-TK4. Other French overseas departments (Martinique, etc.) probably also will change.

All of this callsign switching will be confusing for a time, but it will make the prefix hunters delirious! Dozens of new prefixes will be on the air this summer, most never heard before—another excellent reason to keep up with your DX reading.

Another operating activity in July is the annual French Polynesia Tiurai. Listen for Tahitian stations July 14-21 on the following frequencies: 28600, 21300, 14240, 14180, 7090, and 3800, especially between 0200 and 1000 UTC. The stations will be celebrating their annual festival with a special certificate for working at least three Tahitian stations on at least two different bands. Send your log data and 12 IRCs to Tiurai 1984 Certificate, CORA, BP 5006, Pirea, Tahiti, French Polynesia.

The station that works the greatest number of French Polynesian stations during the festival week will win a handsome trophy: a beautiful engraved mother-of-pearl shell. (Thanks to Russ Forbes WB6GFJ/FO0FB for this news.)

DX Convention

By now, your month of July should be well-filled with DX activities. But if you are still yearning for more, take heart: There's a way to wrap up the DX month in fine fashion. The Northwest DX Convention will be held July 27-29, at the Greenwood Inn in Beaverton, Oregon, just outside of Portland. For more information on the convention, contact Bob Herndon W7XN, Willamette Valley DX Club, Box 555, Portland OR 97207. Who knows, you might even meet the DX editor of *73* magazine there!

So before you decide that the entire month of July is a complete waste, DX-wise, tune up those antennas, work the new Russian prefixes, hang your Tiuria certificate on your wall, and have a few eyeball contacts at the DX convention. And, yes, say hello to the family sometime during the month, so that they don't consider you a *complete* stranger!

LETTERS

OH, HE *NEEDS* HELP!

A number of others are working on wild and imaginative conversions and end up seeking help from those who have already done it. Perhaps someone will be able to provide me assistance as well?

Does anyone have instructions for converting a military surplus ARC-5/T-19 into an allband, all-mode, synthesized transceiver with automatic antenna tuner built-in? If possible, I'd like to replace the 1625 tubes (hard to find) with more common 3-500Zs for full legal power, and transistorize the rest. It should have at least 16K of memory and search/scan capability with priority channel lock-out—at least on all bands above 30 MHz. Oh yes, unless a key jack is included I probably won't be interested. Oh, one thing more: I'd like to be able to use it also as a vacuum cleaner, LNA for satellite TV reception, and wattmeter—at the flip of a 4-position switch.

Anyone who has already done this mod, please send me an SASE; I'll tell you how much you owe for photocopies. Thanks. *73.*

Robert (50-Ohm Bob) Wheaton W5XW
San Antonio TX

HATS OFF AND SALUTES

About 5:00 pm on Monday, April 9, 1984, during a brief trip to California to analyze a budding computer manufacturing company, I was enjoying the California sun in the beautiful backyard of the home of the friends with whom I was staying. Stripped to my shorts, I was stretched out listening to the chatter of happy people on my 2-meter hand-held when I was brought upright hearing, *"Mayday! Mayday! This is KE6HI. Mayday! I need a local contact fast!"*

My first reaction was to answer the distress call, but being pretty unfamiliar with the area, I waited an instant to see if a local would answer. My hunch was right for only a few seconds later I heard, *"KE6HI this is KF6TF. You are loud and clear. State your emergency. This is KF6TF. The handle is Dora. Go ahead."* The message was transmitted in a calm, precise, and authoritative manner.

From my notes taken at the time, here is what apparently happened thereafter. KE8HI, handle Alma, driving on Interstate 5 in heavy traffic during rush hour was following at a fair speed behind a motorcyclist when the cyclist crashed and was thrown onto the pavement and appeared to have a broken leg. The cyclist was at the mercy of the speeding traffic, and KE6HI, instead of swerving to pass the cyclist, chose to slam on her brakes and park in the middle of the freeway in a way to protect the downed cyclist from the certain dangers of oncoming traffic. After positioning her car in a protective position, turning on her flasher warning lights, and assuring herself that the injured cyclist would not be further injured, KE6HI sent out her Mayday call. After passing the pertinent information to KF6TF, KF6TF contacted the authorities and within ten minutes had the police, the fire and rescue team, and an ambulance at the site of the accident. While waiting, KE6HI directed traffic until the police arrived and took over.

Two fine California ladies doing a splendid job, excellently executed in a professional way: Alma Bourhenne KE6HI from Cardiff by the Sea, and Neldora Tuttle KF6TF from Escondido. I was most impressed with how well they did a volunteer job. I think they probably saved the life of the cyclist. Wouldn't it be nice for some of you to send each of them a QSL card just saying, "Well Done!"

Yes, a commendable job done by two fine ladies who know how to handle themselves with courage, efficiency, and dispatch under extreme emergency conditions. I was so proud of their performance that I hardly could wait to get home here in Washington State so I could tell my lovely wife all about it. My wife? Yes, she just got her Novice call, KA7RXM, and I'm mighty proud of her, too!

Christian L. Engleman W7QQ
Washougal WA

DX WORLD

Recently a program I wrote appeared in *73* (February, 1984), "Put the DX World On the Screen." I would like to thank all the many people who wrote me with their comments, suggestions, and their orders. The real pay in doing a project like this is the thanks that I receive from all my fellow hams; lord knows the money isn't worth it. I hope that all the people who received my program were pleased with what they received.

As many people already know, I did a rewrite of the Prefix Locator program for the Commodore 64. I added many features to it that you will not find in the VIC version. Let me list some of the added features.

- A more expanded data list, including cities and all the states in the US of A.
- Two clocks, one local and one GMT.
- User-selectable screen, border, and print colors.
- An MUF forecast in local time and GMT time.
- Printer output routines.
- A machine-language data-search routine. Now data searches take three to five seconds instead of three to four minutes.
- And, recently added, is a sunrise and sunset calculation routine.

This version is available from me or from RAK Electronics. The C64 version is available on tape or disk. A C64 version of one form or another has been available since November, 1983. The C64 version has been updated several times and some older versions don't have all the features mentioned above.

Eugene Morgan WB7RLX

Ogden UT 84404

COME TO THE FAIR

A working amateur-radio station with space-age equipment, an international message-sending service, and the Smithsonian Institution's Marconi exhibit, will demonstrate amateur radio's role in worldwide friendship.

The Louisiana Amateur Radio Exhibition's booth at the Julia Street exit will outline amateur radio's heritage from the experimental days of radio wizard Guglielmo Marconi to disaster communications such as during Gulf Coast hurricanes, the current era of amateur-radio space communications including astronaut Owen Garriott's amateur-radio experiments from the space shuttle *Columbia* last year, and speculation on the hobby's future.

Operators will demonstrate how ama-

teurs communicate today, including the newer modes of color slow-scan television, radio-teleprinter, and computer and space satellite methods, and the standby, Morse code.

Visitors from the world's fair countries of the United States, Canada, Australia, Israel, Liberia, and Peru may send free messages to friends in their countries from the booth, via the hobby's international message system.

Among Marconi's relics on display through mid-August will be a rotary spark-gap transmitter used by early amateurs and a magnetic detector used by radio stations in 1912.

Visiting amateur-radio operators will be allowed to use the station on presentation of their licenses. They will identify themselves with the station's callsign, K5WF, which belongs to Howard T. DeLaneuville of Jefferson, Louisiana.

A unique verification card will be provided to amateur-radio operators who contact the stations and to shortwave listeners who describe hearing it. The QSL is being designed by John Chase, New Orleans historical cartoonist.

The Historic New Orleans Collection is providing a full-time curator, Patricia Tusa (XYL of Nick Tusa K5EF), to watch after the Marconi exhibit, which is being provided through the Smithsonian Institution Traveling Exhibition Service.

Marconi's daughter, Goia Marconi Bragga, has indicated that she would like to visit the exhibit. Plans are being made to have her come in June.

Amateur-radio equipment manufacturers are lending American-made products for use at the booth. Local volunteers have been constructing and designing the exhibit. Many volunteers will be needed to man the booth for the six-month show.

John J. Uhl KV5E, President
Louisiana Amateur Radio Exhibition, Inc.
New Orleans LA 70124

AWARDS

USS COD DXING

NOARS and the *USS Cod* will be on the air again this summer. Northern Ohio ARS members will be operating from the *Cod* starting Memorial Day weekend running daily through Labor Day weekend. Look for operations in the lower portion of the General bands 10 through 80 meters, with special Novice operations on June 16, July 15, and August 18, and Extra operations during the Cleveland Hamfest, September 23rd.

QSL cards picturing the *Cod* and NOARS station will be sent out confirming all contacts, a special 8 × 11 certificate will be available upon request with QSL confirming the two-way contact and $1.00 for handling and postage. Send all QSLs to WD8RZG.

The *USS Cod* is on permanent display as a war memorial to honor the men of the Silent Service and is located at the port of Cleveland between East 9th Street pier and Burke Lakefront Airport. Guided tours given daily. So come on down for an historic visit into the past for an adventure to remember.

BARC CERTIFICATE

A handsome new amateur operating certificate is now being offered by the Bartlesville (Oklahoma) Amateur Radio Club. The purpose of the certificate is to focus attention on the interesting "Green Country" region of northeast Oklahoma, and to emphasize the varied operating activities of the nearly 200 amateurs within that area.

The Green Country award is available to anyone making two-way amateur-radio contact with three hams in the Nowata, Osage, and/or Washington Counties of Oklahoma. All bands and modes are permitted. The certificates will be numbered and issued serially.

Applicants for the award should submit calls and pertinent details of their three qualifying QSOs, plus a $1.00 handling fee. QSLs are not required. Applications should be mailed to W5NS Awards Manager, 1800 Moonlight Drive, Bartlesville OK 74006.

2000TH ANNIVERSARY

To celebrate both the 2000th anniversary of the founding of Trier, Germany, and the 60th anniversary of the New Trier High School ARC, a certificate will be awarded to any amateur contacting a station in *both* Trier and New Trier Township, Illinois (includes the villages of Wilmette, Winnetka, Kenilworth, Glencoe, and Northfield). Contacts must be made in 1984, any band, any mode.

Send QSLs for both QSOs to New Trier H.S. ARC, W9EDC, New Trier H.S., Winnetka IL 60093, along with a large SASE, 54 cents US postage, or 4 IRCs for a non-folded certificate.

To assist amateurs in earning the award, special-event stations will be operated simultaneously from Trier (DL0TR, DL0BBS) and New Trier (W9EDC) on June 30th and July 1st. Operation will be 80–10 meters (SSB and some CW), 15 kHz above General band edges. DL0TR and DL0BBS will also go RTTY and OSCAR 10.

THUNDER ON THE OHIO

The Tri-State Amateur Radio Society (TARS) will operate a special-event station in conjunction with the Freedom Festival and Thunder on The Ohio Hydroplane Races during the Fourth of July weekend.

The station will use the club call W9OG (W 9 Old Glory) which is very appropriate for July 4th. Operations will begin on June 30, 1984, and continue daily through July 4, 1984. Hours of operation will be 10:00 am to 5:00 pm CDT in the lower portions of the Novice and General segments of the 10-, 15-, 20-, 40-, and 80-meter bands. All modes will be used including RTTY.

An attractive 8 × 10 certificate will be available for $1.00 postage to confirm contacts with the station. Certificates will be packaged flat and be suitable for framing. For those who do not wish a certificate, a special QSL card will be sent confirming all contacts. Please include 20¢ postage for the QSL card.

Send QSO information to TARS Special-Event Station W9OG, Attn: M. G. Anderson, PO Box 3284, Evansville IN 47732. For additional information on the special-event station contact me by phone: (812)-424-2306 (days) or (812)-476-5572 (evenings), or write asking to be placed on our publicity mailing list.

STEAM ENGINE CONVENTION

A special-event station will be operating July 13–15 from the Bourbon County Fairgrounds in Bourbon County, Kentucky, to commemorate the annual steam engine convention. This station will be operating with the call of WD4GPO, in the General phone and CW portion, with some Novice activity planned. All amateurs and SWLs working this station during this time can receive a commemorative QSL card from the Pioneer Amateur Radio Club of Winchester, Kentucky; send an SASE to Pete Clough WD4GPO, 425 Bell Street, Paris KY 40361.

SPEEDWAY STATION

The Adrian Amateur Radio Club is having a special-event station, W8TQE, at the Michigan International Speedway (MIS) on July 20, 21, and 22. The frequencies will be 28.625, 21.360, 14240, 7240, 3900 ± QRM. The Novice bands up 10 kHz, 21.110, 7.110, 3.710. This is to celebrate the Michigan 500 Indy-type car race. A special certificate will be offered. Send a large SASE to Adrian Amateur Radio Club, PO Box 26, Adrian MI 49221.

DETROIT ARSENAL

The Tank-Automotive Command ARC will operate W8JPW on July 21, 1984, from 1300–2000Z to commemorate the 43rd year of the Detroit Arsenal, home of the the US Army Tank-Automotive Command. Frequencies: phone 7.274, 21.400, and 146.49 MHz; and CW 7.055 from 1500–1700Z. Put your QSO number and frequency in upper-left corner of outer envelope. Send 9" × 12" SASE for unfolded certificate; otherwise, SASE to: W8JPW, US Army Communications Command, Attn: CCNC-TAC-M, 28251 Van Dyke, Warren MI 48090.

BERNE SWISS DAYS

The Adams County ARC will operate KC9TZ from 1400Z July 27 to 2200Z July 28 to commemorate Berne Swiss Days. Operation will be 15 kHz above the bottom of the General phone band on 20m and 40m, and the Novice band on 15m and 40m. QSL to the *Callbook* address for a decorative certificate.

Cedarhurst NY 11516

BITS AND PIECES

I have an old Apple II computer. According to the date stamped on the circuit board, it was manufactured in late 1979 (I purchased it in early 1980). In the four years I have had it, it has performed flawlessly—until just recently.

The P and the L keys started to

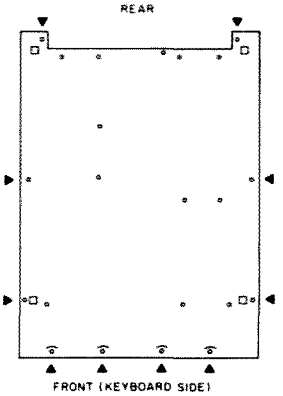

Fig. 1. Underneath an Apple. Arrows indicate screws to remove.

"bounce." Sometimes I would get two or three Ps or Ls when I only wanted one. I ran over to a local computer repair shop and purchased 2 keyswitches. When I returned home, I had to figure out how to take the Apple apart to get at the keyboard—a task that isn't too difficult if you know which screws to remove! To save you from possible aggravation if the need ever arises to take *your* Apple apart, I will describe how it is done. Please note that this information only applies to Apple II computers; Apple *//e* computers are *constructed differently.*

Start by disconnecting the power cord from the computer. Pop the lid off and carefully disconnect all the peripheral cards, disk connector cables, etc. Unplug anything you might have plugged in the game port or the rf modulator socket.

Look at the diagram in Fig. 1. Turn your computer over and set it down on a protective surface. Remove only those screws that are marked with an arrow in the diagram! You should have removed six flat-head Phillips screws and four round-head Phillips screws. Put the screws aside so you don't lose them.

After the screws are out, carefully lift the end labelled FRONT in the diagram up a few inches. It should hinge open. You will notice a DIP connector connecting the keyboard assembly to the main assembly. Using extreme care, gently unplug this connector from the main board and note its orientation (you'll be putting it back later!).

After you have disconnected the keyboard connector from the main board, you are ready to lift the bottom off completely. Set it down in a safe place (where no one is likely to step on it).

Next, to remove the keyboard from the case, simply remove the screws at each of the four corners of the board. If your Apple is a fairly recent one, you will notice that the keyboard has a "piggyback" board connected to it. Removal of this piggyback board is a bit tricky. Locate the two white plastic posts that extend through it. You will notice that these posts serve to hold the boards together by means of tiny plastic expanding tabs. With a needle-nose pliers, squeeze these tabs together to unlock the posts from the board. Carefully separate the boards, taking care to notice that a 25-pin connector must also be separated. To replace this board, first align all of those 25 fragile pins into the proper holes and then push the boards together firmly to lock the plastic posts.

That's all there is to disassembling an Apple. The procedure is fairly simple; about the only tricky thing is removing the piggyback board from the main keyboard. While you're inside your computer, you might want to give the insides a thorough cleaning. You'd be amazed at the amount of dust, dirt, hair, and assorted particles that find their way into a computer!

WHO'S WHO IN NEW-WAVE MUSIC

I received a post card from Wilbur T. Golson W4AV regarding my April column. He said: "Re: 'The End of Amateur Radio': I agree with your thoughts one hundred percent, but the majority of hams don't. I feel that the code test should have been dropped and the technical tests and rules beefed up to keep with today's modern technology. The FCC feels the same way, but it seems that the 'I had to learn it, so you should, too' attitude is far too common. I don't know who David Byrne is, but he may be right. . ."

The reference to David Byrne is regarding a quote I used in the April column: "Watch out, you might get what you're after." For those of you who *don't* watch MTV (and I certainly don't hold that against you), David Byrne is a new-wave musician whose group The Talking Heads sings that line in one of their songs. Next time I'll know only to quote well-known people.

While I'm on the subject of mail, I received a number of interesting ideas in a letter from Charles W. Creasy III (who neglected to give his callsign) concerning the need for a computer operating system designed for amateur radio. Features that such an operating system might incorporate are conversion from one code to another (ASCII, Murray, EBCDIC, AMTOR, etc.) and real-time control of amateur-radio hardware (transmitters, receivers, antenna rotors). One could program amateur-radio applications in the high-level language of his choice and perform any needed function with calls to the operating system. Such programs could be made machine-independent; the operating system, customized for a particular computer, would take care of hardware *differences.*

The concept of an amateur-radio operating system is an intriguing one. If anyone has implemented anything along these lines, I would like to hear about it. In the meantime, I think I'll look at the feasibility and practicality of such a system. I

can see the value of such an operating system for applications other than amateur radio. Many computer interface problems are due to a poor communications interface, and computer-to-computer communications over media other than ham radio is a rapidly growing field.

CONNECTING A COMPUTER TO THE OUTSIDE WORLD

In some of the mail I've received, I have noticed a common problem in interfacing a computer to another device. Much of the confusion is focused on the computer's end of the interface—most hams know how to interconnect ham equipment without too much difficulty.

Most home computers use TTL logic circuitry. These components work with two voltages: +5 volts (or a bit below it) and 0 volts (or slightly more). These two voltage levels are used to represent the zeroes and ones that a computer thrives on. As you probably know, computers represent numbers and symbols with binary numbers. A binary number is a number in base 2 and is written using only the symbols 0 and 1. As with the more familiar base-10 numbers, the value of a particular digit depends on its *place* within the number. For example 0101 would be the number five in binary; there is a one in the ones place and a one in the fours place, adding up to five.

What do binary numbers have to do with computer input and output (I/O)? Everything! Remember that the ones and zeroes are represented within the computer's hardware by the presence or absence of electrical current. By connecting special circuitry to look for specific patterns of current on a computer's internal data lines, devices can be controlled with computer commands. It is this principle that is the basis for all computer interfacing.

Let's look at how the built-in I/O ports on an Apple II computer work. The 6502 microprocessor in an Apple II has 16 "address lines" and 8 "data lines." These lines are simply connections on the microprocessor chip that are used to signal a particular memory address or 8-bit data item to the other components of the computer. By having different patterns of on and off voltages on these connections, different memory addresses and data items can be specified.

Usually, the address lines are decoded by the memory chips; when the circuitry associated with the memory chips sees a particular voltage pattern on the address lines, the data contained at the location specified by that pattern is fed into (or taken from) the 6502's data lines.

Memory chips are not the only components which can interpret the information contained on the address lines, however. It is possible to have other circuits recognize certain addresses. The designers of the Apple II computer used this principle to control the four output lines and three input lines on the computer's "Game I/O Connector." Circuitry inside the Apple looks for certain voltage patterns and uses the presence of certain ones to switch the four outputs on or off. For example, placing the binary pattern 1100000001011000 will turn output number 0 off; the pattern 1100000001011001 will turn it on.

You're probably thinking, "How am I going to get the 6502 to put that bit pattern on the address lines?" The answer is remarkably simple. Just have the computer execute any statement that references that address.

It so happens that the two binary bit patterns mentioned before correspond to the numbers 49240 and 49241 in the more familiar base-10 notation. So, if we execute the Basic statement Q = PEEK (49240), we can flip that output off. Similarly, the statement Q = PEEK(49241) will turn it on. Note that the value assigned to Q is meaningless. It is simply the *reference* to the memory location that does the work. Any variable can be substituted, and the result will be the same.

The off/on locations for the other three outputs are: 49242/49243 (output 1), 49244/49245 (output 2), and 49246/49247 (output 3). Outputs 0 through 3 correspond to pins 12 through 15 on the game port connector.

The Apple also has three inputs that work in a similar manner. By using the Basic PEEK command for locations 49249 through 49251, a value can be obtained to indicate if the input is "high" or "low" (0 or 1). For example, the command Q = PEEK(49251) will assign Q a value less than 128 if the input is high and a value greater than or equal to 128 if the input is low.

Caution: These input and output lines are designed to handle the special voltage and current levels used by the computer chips. Do not attempt to connect any device to these I/O lines without the appropriate interfacing hardware.

Next time, I'll describe how to properly interconnect computer I/O ports with other devices. I'll also cover Atari and TRS-80 computer I/O ports.

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

RADIO AND ELECTRONICS PIONEERS

It is natural that one should wonder whether the wireless telephone is destined to displace our present apparatus [telegraphy]. This does not seem at all probable. In the first place, wireless telephony is now, and probably always will be, very expensive. Wherever the wire will do, it is the more economical... Millions of messages going in all directions, crossing and recrossing one another, as is done every day by wire, are probably an impossibility by radio telephony. Weird and little-understood conditions of the ether, static electricity, radio disturbances, make wireless work uncertain, and such a thing as twenty-four-hour service, seven days in the week, can probably never be guaranteed.—Walter Kellogg Towers, *Masters of Space*, 1917.

Don't you just love the predictions of so-called experts? Every time I read a newspaper article or see a television report predicting the future of the electronics industry, I think of the preceding quote.

Fortunately, the subjects of this month's column—radio and electronics pioneers—didn't hold the same beliefs as Mr. Towers. These were men who were willing to take chances on a dream. They didn't care if their goals meshed with the expectations of society. If they did, our shacks would probably consist of little more than paper cups and strings. (I've got a Dixie HW-101, how about you?)

So let's learn a little bit about the people who made our hobby what it is today. And let's all remember how they bucked the advice of the experts. Ham radio could use a little more of that attitude today.

ELEMENT 1 MULTIPLE CHOICE

1) Which of the following devices was an invention of Sir Hiram Stevens Maxim, father of ARRL founder Hiram Percy Maxim W1AW?
 1) Radioscope
 2) Self-regulating generator
 3) Carbon resistor
 4) All of the above

2) Which of the following men first proposed naming the two electrical poles "plus" and "minus"?
 1) Thomas Edison
 2) Henry J. Faxton
 3) Michael Faraday
 4) Benjamin Franklin

3) English philosopher and chemist Joseph Priestly:
 1) Proposed the inverse square law
 2) Invented the galvanic jar
 3) Discovered the unit of quantity
 4) Developed the practical nicad cell

4) German physicist Thomas Johann Seebeck discovered the "Seebeck Effect," which eventually became known as:
 1) Radiation
 2) Thermal electromotive force
 3) Electricity
 4) Static discharge

5) Samuel Morse constructed his first telegraph from:
 1) Aluminum
 2) An old picture frame
 3) Bits and pieces of old newspapers
 4) Scrap iron

6) Name the two actors who portrayed Thomas Edison in MGM movies during the 1930s.
 1) Spencer Tracy, Don Ameche
 2) Raymond Massey, Cedric Hardwicke
 3) Mickey Rooney, Spencer Tracy
 4) William Powell, Humphrey Bogart

ELEMENT 2 MATCHING

Match the names in column A with the inventions in column B.

A	B
1) deForest	A) Radar
2) Fleming	B) Television
3) Fessenden	C) Teleprinter
4) Baekeland	D) Radiotelephony
5) Hilliard	E) Triode
6) Affel/ Epensched	F) Diode
	G) FM radio
7) Stanley	H) Magnetic detector
8) Shockley/ Brittain/Bardeen	I) Transistor
	J) Bakelite
9) Armstrong	K) Heterodyne
10) Taylor/Young	L) Radio beacon
11) Berliner receiver	M) Tape recorder
	N) Photoelectric cell
12) Elster	O) Circuit breaker
13) Poulsen/ Fessenden	P) Multigrid tube
	Q) Ac transistor
14) Marconi	R) Static power
15) Zworkin	S) Coaxial cable
16) Alexanderson	T) Cascade tuning
17) Poulsen	U) Microphone
18) Morkrum/ Kleinschmidt	
19) Donovan	
20) Langmuir	

ELEMENT 3 TRUE-FALSE

	True	False
1) Zenith, the famous electronics company, derives its name from an amateur call.	____	____
2) The callsigns of the first two FM broadcast stations were KE2XCC and W2XMN.	____	____
3) David Sarnoff, founder of RCA, first rose to national attention by relaying distress messages from the ill-fated RMS Lusitania.	____	____
4) The first US broadcast radio station was WPLJ in Albany, New York.	____	____
5) During World War I, the US Navy's primary school for wireless operators was located at Harvard University.	____	____
6) At the time he discovered radio, Marconi was only 29 years old.	____	____
7) Lee deForest went bankrupt at the age of 33.	____	____
8) Reginald Fessenden was an adopted son of Thomas Edison.	____	____
9) Michael Faraday, of unit of capacitance fame (the farad), died in 1967.	____	____
10) The coulomb—the unit of electrical quantity—is named after Charles Augustin Coulomb (1736-1806).	____	____

ELEMENT 4 SCRAMBLED WORDS

Unscramble these names of radio and electronics pioneers.

RAMINCO	YARAFAD	LAVOT
RETZH	HOM	ROSEM
PRAMEE	YARAFAD	SLATE

THE ANSWERS

Element 1:
1—2, 2—4, 3—1, 4—2, 5—2, 6—3.

Element 2:
1—E, 2—F, 3—K, 4—J, 5—O, 6—S, 7—Q, 8—I, 9—G, 10—A, 11—U, 12—N, 13—D, 14—H, 15—B, 16—T, 17—M, 18—C, 19—L, 20—P.

Element 3:
1—True From the call of the company's founder, E. F. McDonald 9ZN (originally ZN-ith Radio Products).
2—True The experimental stations run by Armstrong in New York and New Jersey.

3—False It was the Titanic.
4—False KDKA in Pittsburgh, Pennsylvania.
5—True Harvard was a major training center for the War Department during the Great War.
6—False He was only 22!
7—True But he made up for it later.
8—False Hardly. He was the son of a Canadian minister.
9—False 1867.
10—True The one and only.

Element 4:
(Reading from left to right) MARCONI, EDISON, VOLTA; HERTZ, OHM, MORSE; AMPERE, FARADAY, TESLA.

SCORING

Element 1:
Four points for each correct answer.
Element 2:
Two points for each match.
Element 3:
Two and one-half points for each correct answer.
Element 4:
Two points for each name unscrambled.

1-20 points—Still in the Dark Ages
21-40 points—Communicator
41-60 points—Radio cadet
61-80 points—Academician
81 + points—Son of the pioneers

HAM HELP

I need a schematic and any technical information on an SBE SB-144 two-meter crystal-controlled transceiver. I will pay any and all copying and postage costs.

Dick Roux N1AED
25 Greenfield Drive
Merrimack NH 03054

Help! I now own a working NC-109 general-coverage receiver. I need information about it so that when it no longer works, I can find out why. (Also, I may want to perform modifications to it.)

Also, I have been having a terrible time trying to connect a Western Electric #1035C3A-type touchtone™ pad to a 500-type telephone set. Any help at all will be greatly appreciated.

Thanks a lot.

Andrew W. Gaunt
52½ Washington Street
Newburyport MA 01950

Help! I am a Novice and I need the manual (or a copy) for the Heath model HW-16 and any modification for HW-16, and also the manual (or a copy) for the Heath VFO-1. I will gladly pay postage and copying costs.

Edward Molser KA2IVD
4376 Coolidge Rd.
Coleman MI 48618

I need an operating or technical manual for a Nems-Clarke Spectrum Display Unit, model 200-3. The unit is a narrow-bandwidth spectrum analyzer, apparently used by the military to monitor the 30-MHz i-f output of UHF or microwave converters. I will pay reasonable copying costs.

My thanks to you for your service. I have utilized "Ham Help" once before and got many offers of help, including long-distance phone calls. Since then, I have helped several others using your service.

Bob Lombardi WB4EHS
2046B Ranee Place
Melbourne FL 32935

I have been a subscriber to *73* for over twenty years. I now have a problem which you might be able to help me with. I am looking to locate a published article or other information concerning the effect of radio frequency transmissions on an implanted heart pacemaker.

Your help will be greatly appreciated.

Maurice J. Hindin W6EUV
10471 La Conte Avenue
Los Angeles CA 90024

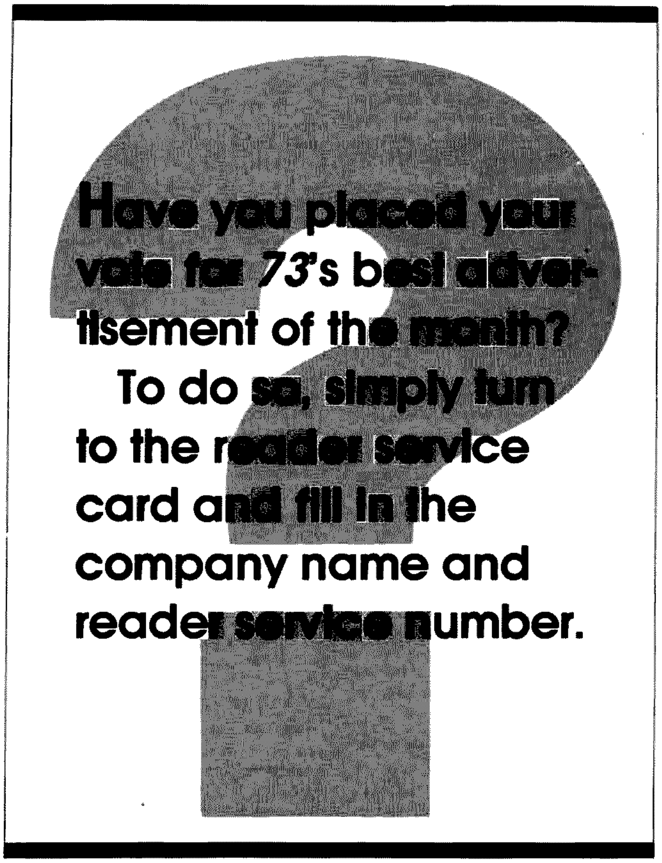
CORRECTIONS

The address for the SW station in Norway, page 49, *73* for April, 1984, should be: Radio Norway, Oslo 3, Norway.

Roger N. Peterson
New Canaan CT



73 INTERNATIONAL

from page 62

to be noted is that under the strong pressure and reaction of the amateurs, the Post and Telecommunications Ministry (MPT), has warmly invited the ARI directors for a friendly exchange of opinions for the first time in Italian radio-amateur history; opening its golden doors to hams, it has made a descent from its throne, receiving their representatives and discussing their problems in the presence of the Minister of Posts, Senator Gava, and the MPT general manager, Dr. Monaco.

Together with beautiful words on the importance of the amateur-radio service, on its social values, etc., words which were absolutely unheard before, as a first step the MPT released the 160-meter band, the 18- and 24-MHz bands, and promised the 10-MHz band (with some frequency limitations) in a very short time. Moreover, the MPT promised to authorize in very short time the 144-and-up repeater network, the free transfers of stations, and mobile operation.

The more controversial matter appears to be the 3.5-MHz band, as the MPT proposes for amateur use only a segment of 100 kHz. A very important and perhaps decisive meeting between the ARI and the MPT will take place soon. I hope to be able to announce a complete amateur victory in the next column.

The most important observation which should be made on this "Italian Affair" is that in a free and democratic country, the radio amateur's community, even if small, like any other citizen's community, can safeguard its own rights while fighting against forces which, at first, could be judged not suitable to be attacked, like powerful government agencies—telecommunications, military, etc.

The Italian amateurs, who had been judged weak and inoffensive by the administration (and just for that reason were kept for decades in a substandard position), suddenly raised a fierce and strong protest when the 3.5-MHz band was practically closed. The battle started from this point and was extended to the other controversial areas like repeaters, mobile operations, and so on.

Open discussions on these matters were kept on the air, a very sharp protest against the MPT, and the ARI, whose action was judged weak and ineffective, then started writing in the technical magazines. Groups of amateurs, and I was among them, started to organize actions through radio, TV, newspapers, and weekly magazines. A petition with thousands of cards, telegrams, and letters was directed to the President of the Republic, Sandro Pertini. The echo of this big noise filtered through the MPT walls, and the MPT, surely fearing negative public opinion, suddenly changed its own behavior in such a way that it was the first to contact the amateurs in order to modify the clamor they were raising.

At present, we are strongly believing that almost all our targets will be hit.

I think that the "Italian Affair" will make history, and also I believe it should be studied deeply wherever similar problems arise in other countries.

AN INTERVIEW WITH SHOZO HARA JA1AN

(JA1AN is President of JARL—the Japan Amateur Radio League, Inc.)

Waite: How many members does the JARL have at present?

Hara: We have 131,000 members. And here in Japan at present there are 565,000 amateur stations.

Q: I know that Japan is now number one in the world in the number of amateur-radio operators. Are the members of the JARL increasing year by year? What is the trend?

A: Yes, there is a gradual increase.

Q: Is it a large increase? About what is the percentage of the yearly increase in membership?

A: Until now the yearly increase has been tremendous, but these days the increase in membership has been slowing down.

Q: Throughout the years, the JARL has accomplished many, many things. Could you just tell us about a few of the more important accomplishments? For instance, I know that the JARL succeeded in getting a "window" at 3.803. That was due to the JARL efforts, wasn't it? What do you think were the most important accomplishments?

A: Let's talk about frequencies. In 1952, when amateur radio was again reopened after the war, the JARL succeeded in getting permission to operate on 14, 21, 28, 50, and 144 MHz. On 40 meters we were given only two channels, which were 7,050 and 7,087.5. Then in December of 1956, 40 meters became a real band and we could then operate from 7.0 through 7.1.

Q: Were you the JARL president during that period?

A: No. At that time I was a director.

Q: I see.

A: In 1955 we got 3.5 MHz. In 1956 we got 435 MHz and 1.8 MHz. Year by year, the JARL succeeded in obtaining more frequencies. About ten years ago we obtained the "window" at 3.803 which you mentioned earlier.

Q: So all of these came step by step.

A: Yes. After that we got 1200 MHz. And then 5 GHz, 2 GHz, and others. All of these came gradually.

Q: Now, moving to more recent accomplishments, one of the things that comes to mind is repeater operation.

A: Yes, we finally got government permission in 1982, and repeaters first appeared last year, 1983. We had been working on that for 20 years!

Q: Why was it so difficult to get government approval for repeaters?

A: In Japan, domestic communications are controlled by NTT and international communications by KDD. No one other than those two entities was allowed to operate repeaters. But we succeeded in having the interpretation of the rules relaxed somewhat in order to accommodate amateur-radio operation of repeaters.

Q: How many times did you visit the Ministry of Posts and Telecommunications (MPT) before you finally succeeded?

A: On the average, I visited the MPT once a week. At the present time, there are 150 repeaters on the air in Japan. And there are 290 repeater applications on file which will be acted upon. So sometime this year there will be more than 3000 repeaters in operation here.

Q: There is a jamming problem on the repeaters, at least here in Tokyo.

A: Yes. Well, especially your club, TIARA, has problems because your repeater is located on top of Hotel Okura, one of the highest points in Tokyo. The question is, what are we going to do about all the trouble that we have been having with this repeater? I have talked to the MPT about this. What we are thinking is to add some repeaters around the hotel to cover almost the same area, so that the number of users on each repeater would be somewhat diluted. The TIARA repeater gets out so far and so well that it attracts a lot of users.

Q: We get the impression that because we are speaking English on this repeater, we are deliberately jammed. I can't imagine the same situation in America, although I have heard there are some jamming problems there, too.

A: Well, it's true that the TIARA repeater is having more trouble than other repeaters. And while it is true that English-speaking hams on that repeater do attract some troublemakers, it is not the main reason for the trouble. The main reason is that it is right smack in the middle of Tokyo, probably the world's most populous city, hamwise, at least. And it is at the highest point in Tokyo, so it covers a very wide area. We think that if a lot more repeaters go on the air in this area, most of the troubles will disappear.

Q: Did you hear about the incident the other night where employees of Hotel Okura actually apprehended a taxicab driver near the hotel who was jamming the repeater?

A: Yes, I heard about that. We know about that and other incidents, as well. We inform the MPT about all of these problems.

Q: Let's talk about the progress in the reciprocal license field.

A: We really thought we could accomplish a reciprocal agreement with the US in early 1982, but here it is 1984 and we haven't succeeded yet. The plan is to begin by having the first Japanese reciprocal agreement with America. Somehow or other we haven't been able to settle certain matters. So we don't have anything yet.

Q: I have heard that the ball is on the US side now. Is that right?

A: Well, actually the problem is here in Japan. In this country, we have a separate station license, separate operator's license, station inspection, and complicated application procedures. In America, you don't have to contend with all of those things. In Japan, to go on the air, there is a mountain of bureaucratic red tape to get through. In America, it's relatively simple, as it is in Germany, too. This is a very difficult problem to overcome.

Q: Do you think it is arrogant of the US to insist on Japan changing its rules to match the American side?

A: No, I don't. Reciprocal means "same." Same rules and procedures. So we're trying to come up with a way to simplify the procedures. The law was changed in the Japanese parliament in 1981, so the stage has been set. The problem now is how to apply the law and to work out details of applying for permission and regulations and restrictions that will apply.

Q: So when do you think we can expect to see a reciprocal agreement with America?

A: I had been hoping for March of this year, but some people are saying it won't come until June or July.

Q: Now on to other items. In 1958, the licensing structure was changed dramatically in Japan with the introduction of a no-code class. This was an accomplishment of the JARL, wasn't it?

A: In 1982, when ham radio was again allowed in Japan after the war, we had only first- and second-class stations, with power limited to 500 and 100 Watts respectively. So the JARL came up with a plan, in 1957, to add two new classes, with power limited to 10 Watts. One was a phone, no-code license, and the other was a CW-only license. This was approved by the government in 1958.

Q: Did you play a part in this, Mr. Hara?

A: Yes, I was the main force behind that.

Q: When did you become president of the JARL?

A: Well, I was already involved with the JARL in 1941, and in 1948 I was working at the head office, although it is misleading to say "working," as I didn't receive any pay. At that time we were working on getting permission to have ham radio restored in Japan. I became a director in 1952, vice-president in 1964, and president in 1970.

Q: So you have been president now for 14 years. Is it a satisfying job being president of the JARL?

A: Yes, I enjoy it very much, although it keeps me very busy.

Q: I know you are already very busy at Mitsubishi Heavy Industries in your regular occupation. What is your job there?

A: My title is Chief Engineer, Shipbuilding and Steel Structures Headquarters.

Q: So I would imagine that this job keeps you very busy.

A: Yes.

Q: How do you find time for the JARL activities?

A: It seems that I am on the go from morning until late at night. As for the company, if there is nothing special going on, I work from 8:00 am in the morning until 10:00 pm at night. During those hours I squeeze in JARL affairs. The company is closed on Saturday, but if there is nothing for me to attend to at the JARL, I go to the Mitsubishi Heavy Industries office

Q: Do you go to the JARL office every day?

A: No, I don't, but I am in frequent contact with the JARL officials as necessary.

Q: Is it true that most of the directors are retired MPT employees? I heard a rumor about that some time ago.

A: No. Not true. There are 20 directors, but not even one is from the MPT. Among those 20 directors we have one president, two vice-presidents, a general secretary, and 16 other directors, 10 of whom reside in the outlying call areas. The other six reside in Tokyo. Also there is one auditor.

Q: Do the directors receive a salary?

A: No. Nothing.

Q: Are you, Mr. Hara, paid for your services?

A: No. Nothing at all. In fact, I sometimes have to spend some of my own money. Even when the JARL holds a party, I have to pay the admission fee like everyone else. The directors are volunteers and don't receive a salary. But we have 140 employees in the headquarters here in Tokyo who are paid a salary.

Q: Are there any salaried employees in outlying areas?

A: In the JA2 area there are three; in the 3 area there are eight; in the 4 area there are

two; in the 5 area there are two; in the 6 area there are three; and so forth. Those people receive a salary from the JARL. Total for the year is about 400,000,000 yen.

Q: One of the recent accomplishments has been in the area of amateur examinations given in this country. It used to be that Japanese could take the exam only twice a year. But the JARL succeeded in expanding the exam schedule. Did you play a part in that, Mr. Hara?

A: Yes, I did. I suggested to the Ministry that they give the examinations every day instead of twice a year. But they said money was the problem. Thereafter, a separate entity was established called the "Examination Center" to which the JARL contributed 100,000,000 yen. This was established in Tokyo only, but soon there will be examination centers like that throughout the country.

Q: On a different subject, I have heard Japanese as well as foreign hams state that one of the problems here is the large number of Novice phone-class hams and their bad behavior at times. What do you think about that?

A: I don't agree with that at all. It depends on the individual, not merely on the class of license they happen to hold.

Q: Mr. Hara, when did you first become interested in ham radio?

A: I first became interested in ham radio in 1938 and I became a ham in 1952, with my present callsign, JA1AN.

Q: May I ask how old you are?

A: I am 57; I was born on September 26, 1926.

Q: What bands are you active on, Mr. Hara?

A: Well, I'm too busy to be very active on the air, but when time permits, I like to get on 6 and 2 and 430 MHz.

Q: Are there any other hams in your family, Mr. Hara?

A: There certainly are. My wife, Yoshiko, is JA1ECQ, my daughter, Hisako, who is married and has a child, is JG1QIK, and my son Keizo is JG1WTK.

Q: Do you have any hobbies besides ham radio?

A: Yes, I am an equestrian. I like to ride horses and I belong to a riding club, and I ride whenever I can find the time.

Q: On behalf of 73 magazine, I'd like to thank you for taking the time from your busy schedule to talk with us today.

A: Thank you. It was my pleasure.

AMATEUR RADIO IN LIBERIA

It is not difficult for an American to obtain an amateur-radio license in Liberia. If he holds an American license that is current, he simply presents it at the Ministry of Post and Telecommunications and receives the equivalent Liberian license. Under normal circumstances this can happen within twenty-four hours. If he does not hold a current American license, he will receive his Liberian license upon having passed examinations in international Morse code and in amateur-radio theory. The theory examination consists of basic electronics, national and international regulations concerning amateur radio, and common amateur practice. In general, these tests are very similar to those given in the States.

Regulations and procedures for obtaining amateur licenses differ from one country to another, and it is not surprising that some countries restrict the privilege of operating amateur radio to their own citizens. An expatriate simply cannot obtain a license at all. It is necessary, therefore, for any given country to investigate the requirements of that country.

The office of the Ministry of Post and Telecommunications of Liberia is located in the post office building in Monrovia. It is open every working day and there is always someone there to give service or direction.

If the person who is seeking an amateur-radio license is in need of instruction, he may go to the Ministry and make known his needs. They will direct him to a place where instruction is available, and it is free. There are two organized classes in amateur radio in Monrovia each year, and individual instruction is available for anyone who is not able to attend one of the classes. Like courses are being organized in some of the other cities.

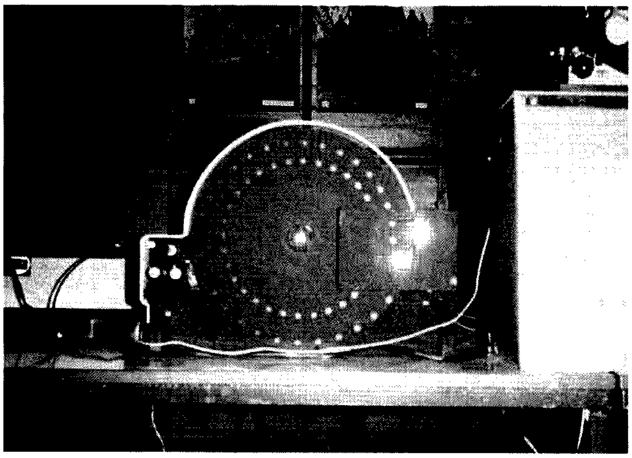
In Liberia, the amateur-radio association has been entrusted with the task of instructing and testing applicants for an amateur license. The president and his officers are very generous with their time and will schedule an examination for *one person* if the need arises! Whatever the case may be, when an applicant has passed the examinations, the exam papers with the grade are sent to the Ministry along with a letter recommending that the applicant be given his license and call letters, and this is usually done within a day.

In this country, there are only two classes, the Novice and the General. The Novice class has privileges similar to the Novice class in the States—with one notable exception. Here, the Novice may operate phone at 7.060 MHz; this is the frequency used by the West African Net and so allows the Novice to take part in the net activities. In Liberia, this becomes very important because the net is a vehicle for passing messages from one part of the country to another.

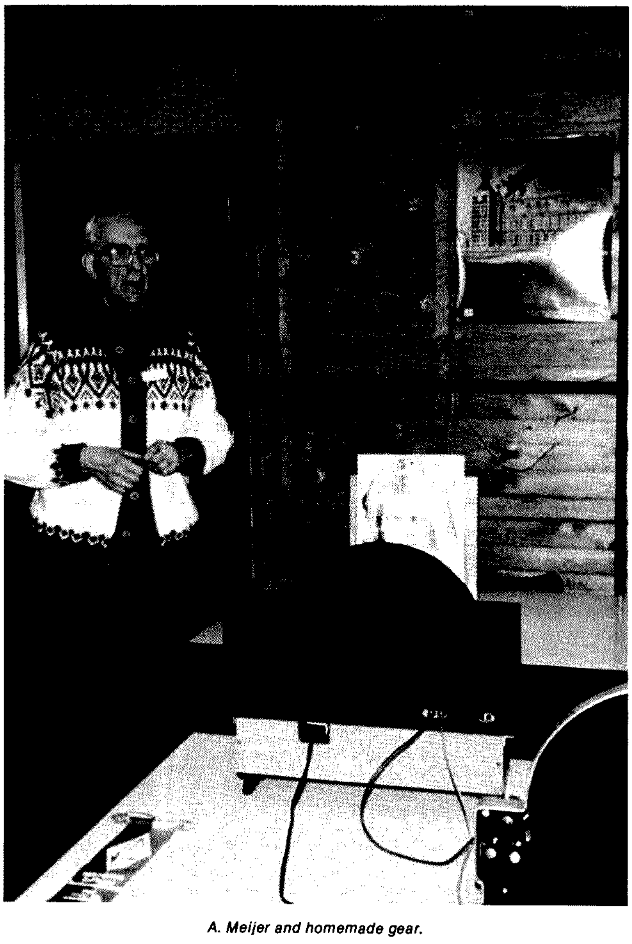
The General class has all the privileges which are allowed to amateur radio in Region I. There is no higher amateur license in Liberia. It is a fact, however, that when a Liberian General license is presented for the equivalent American license under the reciprocal agreement between the two countries, it is the American General license that is awarded, not the Extra.

There are many Americans who come to Liberia and establish residence for two or three years—or for much longer. The greatest number of these are missionaries, but there are also Peace Corps volunteers and businessmen as well as members of the diplomatic service. Many of these people look to amateur radio as a means of keeping in touch with home. This article should be a real help to them. On a much broader spectrum, chances are that American amateurs will enjoy just knowing how it is done in another country.

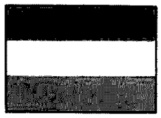
Should anyone wish further information, please feel free to write to me personally at the address given above.



Nipkov disk in action.



A. Meijer and homemade gear.



THE NETHERLANDS

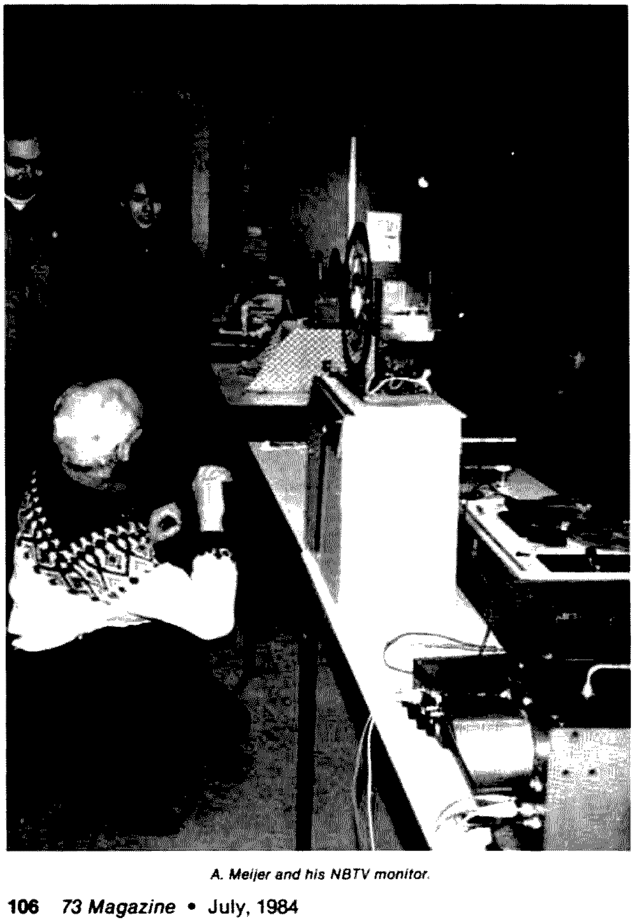
Henk Meerman PD0DDV
Zandvoorterweg 33
2111 GR Aerdenhout
The Netherlands

In the December, 1983, issue of this magazine, I told you about the NBTVA (the Narrow Bandwidth Television Association), a club with only a handful of enthusiastic members with two things in common: ham radio (most of the NBTVA members are hams) and a desire to construct mechanical television equipment.

The parts that they use are Nipkov disks, mirror drums, motors, etc. As a member of this association, I made a recent visit to the meeting that they hold once a year. This year the meeting was held in the southern part of my country, in the city of Eindhoven. I'll give you a full report of what there was to see.

On the 18th of March, some fellow hams and my YL and myself, of course, drove by car to Eindhoven. Because it was on an early Sunday morning when we started, it was very quiet on the roads and that's why we had a safe journey to Eindhoven and the club where the meeting was. All we had was the address, but, as promised, a friendly operator was listening for any visitors, and when we gave a shout on 145.15 MHz, we got an immediate response from PA0PWA, who talked us to the right spot.

A. Meijer and his Nipkov disk.



A. Meijer and his NBTV monitor.

When we entered the building, we got a warm welcome from Mr. A. Meijer, the president of NBTVA, and his wife. He had brought some nice gear: a camera and separate monitor, both with Nipkov disks, all homemade and all in working condition. Most members use Nipkov disks made by Mart Schouten PA0MJS.

Mart, who in daily life is a mechanical designer, makes the Nipkov disk with an almost unbelievable accuracy. He uses aluminium for less weight. Since it is a hell of a task to make a good Nipkov disk, most of the members knock on Mart's door to buy one from him.

Mart brought a single monitor (television) with an antique-style wooden cabinet and a combined camera/monitor which was a real piece of craftsmanship. We also had a chance to see a part of the original equipment as used in the early days of TV by PA0DXY. PA0DXY made broadcasts with narrowband TV in 1935 and 1936. Before we went home, I got good advice from Mart about how to improve my equipment, and I bought one of his new-design disks.

THE EVOLUON

Being in Eindhoven, we took the opportunity to visit the Evoluon. Evoluon is the name of a building where a permanent exhibition is held about science, communications, computers, energy, and mathematics. When you visit Holland, it is a must to see it. It gives you a good example of the state of the Dutch electronics industry today, and it is presented in a popular way so that even minors can enjoy it.

The Evoluon is owned by Philips Company, the well-known manufacturer of electronic equipment in Holland. It has its own amateur-radio station with the callsign PE2VO; it is active on most of the ham bands.

After this visit we drove home, arriving at 6:00 pm. We looked back on a very interesting and nice day, although we were all a little bit tired because we had an early start.

SIX METERS DEAD! SUNSPOT CYCLE 21 GONE!

That's what everyone was saying, but after the ZL summer "silly" season, six meters is far from from dead, even if sunspot cycle 21 has gone. From Kerry ZL2TPY, New Plymouth, this report on some of the six-meter activity over the period mid-December to the end of February shows that 6 was very active in this area.

Within that period, Kerry worked about 720 QSOs with just over 200 different stations in 29 countries, which included VKs 1 through 6, 8, and 9, JAs 0 through 7, FK8, FK0, H44, 3D2, YJ8, ZL8, ZL4/C, and all ZL Districts. All the contacts were worked using 10 Watts USB into a home-brew 5-element yagi, 50 feet up on a hill, one mile from the sea at New Plymouth.

New Plymouth, on the west coast of ZL's North Island, appears to be the "Hawaii of the South" for ZL-VK contacts. (It must be the iron sands or Mt. Egmont attracting the signals.) Many VKs commented that ZL2TPY was the first and last signal heard each day on 6 meters from ZL and one of the strongest stations heard in many years. The same location appears to be favorable also for 2 meters and 70 cm with over 50 VK2 and VK4 2-meter SSB simplex contacts notched so far.

As this sunspot cycle 21 dies away, sporadic-E and F_2 were thought to increase, which seems to be borne out by this year's summer activities, and ZL1MQ, one of our long-standing 6-meter enthusiasts, says it's the most intense sporadic-E summer he's known in 30 years of 6-meter work.

Some of the highlights of Kerry's summer activities included working back-scatter propagation on several occasions with VK and ZL stations; the QRM and pileups on 51.1 MHz with JA were just about unbelievable—about 20 times worse than a DX Field Day contest on HF. Of the back-scatter contacts, Kerry worked VK2DFW, both beaming 260°, 5/7-5/9 signals for about 10 minutes, no signals at all beaming direct, and on a couple of occasions made contacts west to east coasts of the North Island lasting about 45 minutes, all stations beaming 30°, again with no direct-path signals whatsoever. On another occasion, back-scatter was found in all directions for more than two hours, and Kerry was able to work ZL1BXH, Kaitaia, about 400 miles to the north in a direct line, both stations beaming north for a QSO which lasted about 20 minutes.

As Kerry says, "A most exciting and unpredictable band, 6 meters, and it's not dead yet."

Another possible first during all this 6-meter activity was the ZL/VK YL-to-YL QSO when Mary VK4PZ, Rockhampton, Queensland, worked Carol ZL2VQ at Kerry's QTH in New Plymouth. Another 6-meter report from Bill ZL2CD, a long-time 6-meter man, confirms Kerry's information. Bill says the summer's sporadic-E season was one of his best for many years, with the appearance of some rare DX stations. The large number and the intensity of the openings made the band more like 20 than 6 at times.

In all, during December, Bill worked numerous VKs on 24 of the 31 days in the month, as well as the following DX stations: VK0 (McQuarrie Island), VK9 (Norfolk Island), ZL4/C (Chatham Islands), FK8, P29, I44, JA, and FO8. The most common VK beacon that Bill ZL2CD in Wellington could copy almost every day in December was VK2RSY, 52.42 MHz, as well as the VK television sound on 51.74, 51.75, and 51.76 MHz.

And still with the very high frequencies, another old ZL record was broken on January 15, 1984, when the 19-year old 144-MHz overseas record changed hands. ZL3AFN, Westport, South Island, made contact with H44SR, Malaita, Solomon Islands, a distance of 3769 km (2341 miles), but before the record can be ratified, confirmation has to be received of the QSO.

BITS 'N' PIECES

By the time this column goes to press, the successful Kermadec DXpedition will be an historical event. They are there at the time of this writing and have ZLs 1AMO/8AMO (Ron), 1BQD/8BQD (Rolly), 1AAS/8AAS (John), and ZL0AJW/8, otherwise known as W6REC (Deane Ausherman, who was invited to take VK9NS's place) in the DX team. From the sounds on the bands, they are being made to work hard and long, but then that's what DXpeditions are all about when the country is so sought after by amateurs all over the world. I did hear that one member of the team fell asleep during a personal QSO with home, and as you can imagine, that didn't do down too well with the XYL. But all was rectified with a phone call the next day when he was refreshed and awake.

But, remember, if you failed to work this group, don't forget Warwick ZL8AFH is resident on Raoul as a member of the Met station team located there, and, work load permitting, he will be operating as often as he can for several months yet. We all hope his rig troubles reported in the Australian column in the April *73* have been resolved.

The Kermadec Islands are situated about 600 miles northeast of ZL, and apart from the Meterological Station, are an uninhabited Nature Flora and Fauna Reserve area administered by the New Zealand Lands and Survey Department. The largest northern-most island, Raoul Island, the location of the Met Station, is also known as Sunday Island (7260 acres of volcanic origin with a large crater occupying much of its area). Though the highest point is only 1760', its surface is broken by deep ravines and rocky spurs that end at the sea as steep cliffs, which make landing a very difficult operation. The Met Station is serviced once each year by boat for main stores, etc., but there are periodic servicings of the station with mail and consumable stores by air drop from an Air Force Transport plane.

The DXpedition group travelled to the Kermadec Islands aboard the 15.5-meter yacht, *Shiner*, captained by an Englishman, John Taylor. Besides the amateurs, there were five scientists from Auckland University on board led by Dr. John Craig, who intended to carry out scientific studies on Raoul Island. Landing at Raoul Island is always extremely difficult because there is no safe beach area, shelter, or anchorage, but only rocky steep cliffs right to the water's edge and difficult sea swells most of the time. It is possible to land only in good weather conditions. After unloading is completed, the crew of the boat must stay aboard at all times in order to move the boat out should the weather deteriorate.

A few days after the party had arrived and established itself on Roaul, the weather caused the yacht's captain to move from the area near the Met Station around to the southwestern coast of the island to Boat Cove to shelter. However, the wind and seas increased and forced the *Shiner* onto the rocks at Boat Cove. The crew was able to land safely, but the *Shiner*'s ferro-concrete hull was badly holed and the yacht is now a write-off.

Plans have now to be made to evacuate the yacht's crew, the team of scientists, and the amateur DXpedition from the island when a suitable vessel is available to be diverted to Raoul Island to effect the rescue operation.

Over the years there have been amateur operators serving with the Met Station team, but the first occasion that Raoul Island was put on the air was in 1947 when Lew Sharman ZL2IC of Napier, then ZL1TZ, the Post Office radio operator with the station team, fired up the station CW transmitter on 80 and 40 meters. Later, after pondering how to get on phone with a CW-only transmitter, Lew found a way to use the modulator of the long-wave phone transmitter sitting next to the HF CW rig he was using to allow him to operate 80 phone as well. The method used (not recommended normally, of course) was to couple the HT from the CW transmitter to the modulator of the LW transmitter via a twin power cable and a wafer switch and so modulate the CW transmitter with the LW rig's modulator. Lew had many enjoyable QSOs from April to the end of the year when his tour of duty on Raoul Island ended. He was followed by another amateur in the 1948 team, when George Bourne ZL8UO was stationed on the island, but George was not very active during his tour of duty.

Old-Timers Club 50-year certificates were issued recently to O. W. Martin ZL2OZ of Dannevirke and C. J. Barnes ZL2QH of Masterton, marking milestones in their respective amateur careers.

FM IN POLAND

Very popular in West Europe is a developed system of relay-station communication on ultra-short waves. Phased-out professional USW equipment usually gets to hams. Radiotelephones working on 144 MHz are no longer taken to pieces but are returned and used as local communications facilities. The USW Convention in Krzeszowice allocated frequencies of the FM subband 144 MHz to each province of Poland. This enabled directional antennas for attempts at long-distance communications and reduced the number of radiofrequency interferences.

The Polish firm Omig produced, and PRAA (Polish Radio Amateurs Association) distributed, several hundred sets of quartz-crystal resonators for different frequency channels. During several years of FM activity, Polish radio amateurs established many local contacts using nondirectional antennas with vertical polarization. They have been using radiotelephones as auxiliary means of communication trying to work on CW and SSB, too.

To not have too many irons in the fire, the greatest number of channels for every transceiver is necessary. Some attempts with variable-frequency oscillators or frequency synthesizers have been made. But at present it is not even possible to increase the number of channels by reduction of frequency spacing from 25 MHz to the European standard, 12.5 kHz, by reason of too broad quartz-crystal resonators or lack of them. The PRAA is going to repeat the order for crystals from Omig to improve the situation in some measure. For the time being, only one relay station, SR9E, working on R0 channel (input 145 MHz, output 145.6 MHz) enables a few hams to increase the range of their communication on the 144-MHz band. Polish hams expect that in the future they will be able to get newer types of radiotelephone and quartz-crystal resonators for 10.7 MHz, with frequency spacing at 12.5 kHz. This would create new possibilities.

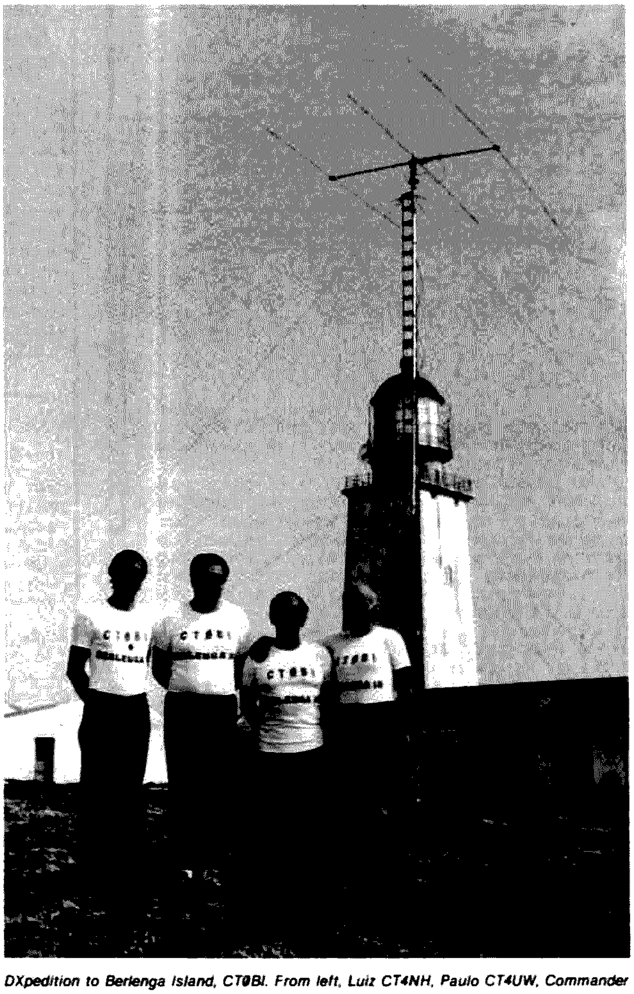
NEWS HEADLINES

State Radio Surveillance informed PRAA of rules of operational use of the amateur band, 1.8 MHz. The interval between 1830 and 1850 kHz is available for holders of the first-class licenses without limitation of power. The intervals between 1750 and 1800 kHz, 1810 and 1830 kHz, and 1850 and 1930 kHz can be given if seriously requested by interested individuals.

Licenses are being brought up to date in great numbers although there are some cases of refusals. The main Verification Board at PRAA took over the function of Appeals Committee.

Work on a revision of articles for PRAA has begun.

The Presidium of PRAA has initiated preparations for elections for the National Congress of PRAA.



DXpedition to Berlenga Island, CT0BI. From left, Luiz CT4NH, Paulo CT4UW, Commander Patricio, and Paiva CT1AFN, REP's vice-president.

QRZ, THIS IS CT0BI, BERLENGA ISLAND, QRZ

As we said before, REP members CT1AFN, CT4NH, and CT4UW were active from Berlenga Island. We just received an update report about that event.

Having our very successful conversations with the Portuguese Navy and local telecommunications authorities, we got the necessary permission to operate from Berlenga Island (a natural reserve where one can find thousands of seagulls, rabbits, one donkey—known as Gerusa—and its favorite food, a very rare specimen of little flowers) with the special (very) callsign, CT0BI. It was assigned for the first time ever, so was a new one for everybody; also, the island was valid for the IOTA Award, with IOTA's reference number being EU-40.

Berlenga is the biggest of a group of islands (Archipelago das Berlengas) located 8 miles off the west coast of Portugal, at the location of the city of Peniche (50 miles north of Lisbon). It is famous for the surrounding transparent waters, making it the ideal spot for underwater exploration. There are monumental grottos like cathedrals of rock that in some cases cross through the island from one side to the other. It is 800 meters long and 300 wide, with the highest point at about 80 meters, where a lighthouse is located, under Navy jurisdiction.

Paulo CT4UW, Paiva CT1AFN, and I, and Frigate Commander Patricio, representing our sponsor (the Portuguese Navy), left for Berlenga in an old fishing boat, the *Ilha da Berlenga*, in bad weather—it was raining, with high winds, and the Atlantic Ocean was very hungry! After an hour of travel, we faced the problem of carrying all boxes, bags, masts, antennas, cables, etc., two miles to the top of the island. Fortunately (for us), Gerusa, the fat donkey, stopped for a while to eat those rare flowers and helped us with that job.

Very soon after our arrival, CT4UW and Patricio were erecting our TH3JR on the top of an existing 40' aluminum tower, still under strong winds and rain. In the meanwhile, I put up 40- and 80-meter half-wave dipoles, hanging them from the top of the lighthouse.

On March 14, at dawn, commemorating our first evening on the island, we experienced a terrible storm and a lightning hit directly on the top of the lighthouse, exactly 40 meters from the place we were sleeping! Fortunately, all rigs were left discon-

nected from antennas and power, so we had no damage, contrary to what happened in the lighthouse where all the electric cables and motors were burned.

Due to the fact that we were authorized to use the CT0BI call only on March 16, 17, and 18, we spent two days visiting the island with its marvelous landscapes and fishing and finished final details in our shack, located in the ex-radio room of the lighthouse.

Our rigs (FT-107M, FT-DX500, FT-101E, Drake VHF gear, etc.) looked very insignificant next to the Marconi transmitters and respective power supplies. Like big refrigerators, they "looked" at our Yaesu gear with a glance of superiority.

Testing 40 and 80, we noticed a high static level (crown effect in all coax cables) which led us to reduce our activity on those bands, avoiding burnout of the finals, saving them for the other 3 bands.

Our meals were splendid because our friend, Commander Patricio, was definitively a super cook! Dish of the day: beans.

At 0000 Friday the 16th, we began CT0BI operation. The first QSO on 40 was with CT1ALF.

To be on the *other* side of the pileup (a sensation already experienced by the author during contests) was a new experience for the other two fellows, CT4UW and CT1AFN, respectively on HF and VHF, where they proved to be keen operators.

Being called by "hot DX" like HV3SD, T77V, and UVs on 40, plus being asked about QSL information... it's too much! We made 4071 QSOs, 1152 of them with US hams, a score possible due only to the fact that they really were very good operators.

The nice QSL cards were graciously offered by the Municipality of Peniche, and to end the story, I would like to thank Fonseca CT1CGO, who helped us from the beginning.

QSL information for CT0BI: CT4NH and CT4UW.

A brand new QSL card has been published by the Portuguese National Tourist Office, to be distributed free to licensed hams in this country. The front cover shows us a portrait of an antique map, as background, and an old Portuguese caravel of the 15th-17th century period. This color card has a very fine look, and we're really hoping for a second issue. Another effort of REP and PNTO.

W5LFL VISITED SWEDEN

Together with other astronaut colleagues, Dr. Owen Garriott W5LFL visited Sweden early in February. It was a short stay without publicity, but Radio Sweden International had a brief interview with Dr. Garriott on the DX program, "Sweden Calling DXers," on February 28. SCDX is aired every Tuesday as a regular and very popular DX program on shortwave.

Owen Garriott had been in Sweden once before, in 1953, when he was in the Navy aboard the *Vincennes*. On both occasions, W5LFL and Henry SM5WK met each other in Stockholm. Over 30 years had passed between these two meetings. Friendship through ham radio! Isn't it fantastic?

NRAU MEETING IN STOCKHOLM

The member societies of the Nordic Radio Amateur Union, NRAU, are EDR Denmark, FRA Faroe Islands, IRA Iceland, NRRL Norway, SRAL Finland, and SSA Sweden. This time SSA hosted the meeting held in Stockholm on March 17 and 18, 1984. It is of great value to get together and to be able to discuss common matters on a personal basis. We were especially happy that also Martin Haasen OY7ML and Kristjan TF3KB were able to travel this far to participate in the meeting.

Beside the Nordic matters, like review of the rules for the Nordic Championship in Amateur Radio Direction Finding (ARDF) and coordination of 2-meter repeater channels for repeaters located close to national borders, most of the time was spent on the hundreds of motions from Region 1 member societies to the International Amateur Radio Union conference in Cefalu, Italy, mid-April.

The wide variety of topics included a motion from the Radio Sports Federation, Soviet Union, "Compulsory of hosting national flags and playing anthems at the ceremony of awarding championship winners" in contrast to the one from Radio Society of Great Britain about uniformity in "the measurement and presentation of performance data on amateur HF receivers"!

ARDF NORDIC CHAMPIONSHIP

The Finnish SRAL is holding its annual summer-camp Field-Day week in Kuopio, Finland, which is in the OH7 call area. This time the Nordic Championship in Amateur Radio Direction Finding will take place during that event on July 21-22, 1984.

ANNABODA MEETING 1984

VHF-UHF-SHF enthusiasts have their summer get-together in Annaboda, a few miles west of the city of Orebro. Besides the fun of eyeball QSOing, there are a lot of antenna project activities. The antenna-gain competition is very popular. This year there will even be fox hunting (ARDF) on 10 GHz. Usually there are visitors coming also from the other Nordic countries and West Germany. This year it might be a little too early for the tourists as the dates for the meeting are June 8-10.

9Y LICENSES FOR NONRESIDENTS

We often are asked by amateurs planning to visit Trinidad and Tobago about the possibility of getting a 9Y license to allow them to operate during their visit. I shall attempt this month to outline what is involved and mention the problems faced.

At this time, the Republic of Trinidad and Tobago has reciprocity with only one other country in the world—the USA. Prior to 1976, the year that Trinidad and Tobago became a Republic, reciprocal agreements were in effect with all member countries of the British Commonwealth (UK, Australia, Canada, etc.). After 1976, these agreements were automatically cancelled. Unfortunately, the government here has not yet found it possible to renew these agreements, and this has complicated the issue of amateur-radio licenses to visiting hams. Each application from a non-US ham is, therefore, treated individually.

The TTARS has tried on several occasions to have the matter rectified but has had little success. This is apparently due to the fact that the new Telecommunications Act is being prepared.

Any US citizen visiting Trinidad and Tobago and wishing to operate here should be prepared to submit bona fide proof of US citizenship, along with both the original and photocopy of their US amateur-radio license, to the Telecommunications Officer in Port-of-Spain, the capital city. Only General-class or higher US licenses are submissible. It is not possible to apply for a license via mail, prior to arrival, as the interested party must apply in person to the officer for the license.

If the Telecommunications Officer approves, the applicant is given a letter to be taken to the Wireless Division of the Department of Customs and Excise who will then issue the license upon payment of the appropriate fee. A 9Y license costs TT$14.50 (or about US$5.95) when first issued and is renewed annually on its anniversary date at a cost of TT$9.60 (or about US$4.00). Visitors will be issued only a portable callsign, i.e., home call/9Y, unless they can provide proof that they will be resident in the country for a period of one year or more.

Any non-US amateurs visiting Trinidad and Tobago who would like to apply for a 9Y license are advised to bring with them all possible documentation to prove their qualifications, e.g., City and Guilds RAE certificate, in addition to their local license and passport. As mentioned before, each case is dealt with on its own merits and the TTARS is unable to assist in the matter.

There is, however, a more serious problem encountered by the visiting ham who wishes to enter the country with amateur-radio equipment. Unless the visitor has a valid 9Y license, the Customs Department at the port of entry will not allow the equipment to enter the country, and it will be detained until the license is obtained and produced. When the license is presented to Customs, the detained equipment will be released only either upon payment of Customs duties (30% of market value), with Purchase Tax of 45% payable on certain items such as linear amplifiers, or by posting a bond which is refundable after the equipment has been exported from the country. There are several catches related to the posting of the bond that are worth noting:

(a) The paperwork involved takes an average of ten days to complete.

(b) The services of a Customs broker are required to prepare the necessary documents.

(c) The broker must be paid for his services.

(d) It takes a minimum of three months, after the equipment is exported, before the bond is refunded.

(e) Refund of the bond cannot be made through the mail.

Unfortunately, the TTARS is unable to assist in this process at this time, although individual amateurs may be able to lend limited assistance if contacted and arrangements are made sufficiently in advance of the anticipated arrival.

NEW EXECUTIVE ELECTED

The Annual General Meeting of the TTARS was held on Monday, March 12, 1984. The following members were elected to office to serve for the 1984/85 year: president, "Nick" Percival 9Y4NP; vice-president, Ian Hart 9Y4IH; secretary, Bernard Ashby 9Y4BA; treasurer, Al Christopher 9Y4LF, and committee members, "Tony" Lee Mack 9Y4AL, Neil Wilson 9Y4NW, Frank Brooker 9Y4VU, Arnim Rudder 9Y4AR, co-opted, and Edward Hay and Denise Lee, associates.

W2NSD/1 NEVER SAY DIE

ARE YOU GAME?

If you're into DXing, you've read about the two recent DXpeditions to the Republic Of China (Taiwan). One was Italian and the other Japanese...so I wasn't completely surprised when Tim Chen BV2A, for years the only licensed amateur on Taiwan, suggested that it was getting to be time for an American DXpedition to BV.

Tim talked to me while I was attending a computer show in Taipei. BV is still relatively rare, so I agreed that such an operation would be great fun...an opportunity for some American hams to experience the excitement of being on the business end of a DXpedition...but without the miseries you often have to go through.

Taiwan is a fantastic place to visit. There are friendly people, great food, incredibly low prices, and amazing sights. Even though I get there once or twice a year, I always look forward to it and enjoy it. I'd sure like to get you to Taipei for a few days; you'd love it. It would be a DXpedition you'd remember the rest of your life. Before I go into details on the DXpedition, let me tell you how I happened to be visiting Tim.

Commerce Tours runs a two-week trip every spring which coincides with computer shows in Tokyo, Seoul, and Taipei. Since it's important for me to keep up with micro developments worldwide, I try to make this tour. Also, this time I was looking for some computer products which I might be able to import.

Commerce was able to let me start a day late on the trip so that I could get an honorary doctorate degree and give the commencement address at Central New England College in Worcester, Massachusetts. Readers of my editorials will not be surprised to learn that I gave a talk on my favorite subject: how you, yes you, can get rich. It seemed like a good message for the graduating class of this outstanding college.

I was a bit intimidated when I saw that my commencement predecessors had been Ted Turner, Bob Hope, Malcolm Forbes, and Frank Perdue. While I hadn't heard their talks, I felt that mine might be of more personal importance to the graduates and certainly right in line with the school motto: "Yes, You Can!" It came off fine and the resulting enthusiasm got me started on an "I Can" book during my Asian trip. I wrote on my lap computer during flights, in waiting rooms, and on buses.

When the graduation ceremonies were done I was whisked to the airport for a flight to Los Angeles...and then Tokyo. There, we went to both a microcomputer show and an office-automation show, getting a full dose of both the low and high end of Japanese microcomputers.

The next step was Seoul, where the shopping is great if you like $9.00 New Balance sneakers and $10.00 Hang Ten suitcases, but it was a bomb for computers. An American outfit had taken over the yearly computer show and apparently alienated just about everyone. I think the whole show took less than ten minutes to see. The hundreds of small Korean computer firms passed it by. This was hard on our group, many of whom had rather good budgets for buying computer products for US distribution. Oh well, maybe we would do better in Taipei.

We did indeed. The Taipei computer show had over 200 exhibitors and much business was done. I got some excellent quotes on products I want to have made.

No trip to Taiwan is complete without an update on the ham

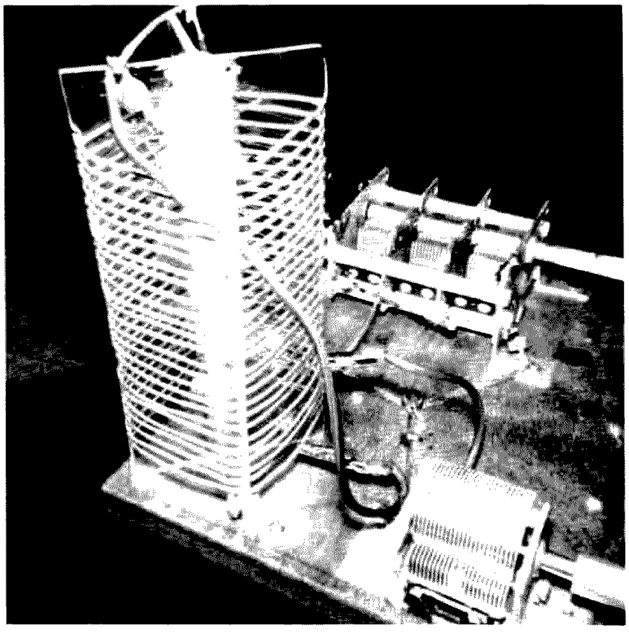
Top-Notch Tuner Time

Can't get your signal out of the backyard? Build KC2NT's antenna matcher and hear what you've been missing.

This tuner has been used effectively to feed the helical antenna described in the May, 1983, issue of *73*.[1] It is a developmental outgrowth of a random-wire tuner used successfully for many years with a 9.14-meter (30-foot) whip placed 15.2 meters (50 feet) above ground. The tuner has been employed with an endfed wire 19.5 meters (64 feet) long on 80 through 10 meters. It was recently used to load the house rain gutter pipe system to complete a Rochester NY/Pittsburgh PA QSO on 40 CW with 20 Watts output on my rig.

In development of this tuner, my goal has been to create a system for coupling a transmitter with 52-Ohm or 75-Ohm output to any 52- or 75-Ohm coax-fed antenna. The tuner assembly contains a couple of high-capacity condensers and a 12.7-cm-long (5-inch), 7.62-cm-diameter (3-inch) coil. However, *this circuit is not the familiar pi coupler device* as will be evident later on in this article. A noteworthy feature of the tuning unit is the greater selectivity exhibited on transmit and receive.



Antenna tuner showing the tuning-coil system and the common ground point for tuning capacitors.

Description

The general tuner configuration resembles somewhat a pi coupler output with an LC series-tuned input in place of the pi input capacitor. Filter tables describe the input system as a low-pass m-derived series half section. The output section is listed as a low-pass constant-k output half section. The fundamental tuner design is shown in Fig. 1. However, the tuner of Fig. 1 is easily simplified by replacing the series inductor as shown in Fig. 2. Note the optional capacitor bank of 3 × 500 pF. This is necessary on the 75/80-meter band with some aerials, e.g., the helical antenna. Upon close inspection of Fig. 2, one can see that the shorted portion of the coil is really two inductances in parallel with a ground return by way of the 500-pF tuning capacitor.

As the 500-pF capacitor is tapped at the various turns of the shorted inductance, the inductance of the paralleled coils changes in value. This method has proven quite effective in helping get the proper antenna-matching impedance. The 500-pF capacitor acts as a kind of band-spread device to cover small increments within the band from one end to the other. The output capacitor should require little trimming after it is set for the particular band. For some random antenna configurations, the tuner input/output connections are sometimes reversed; this seems to be especially true at the 20- through 10-meter bands.

Construction

My first tuner model used a length of B & W commercial coil, stock #3033. The unit is wound with #12 wire at 6 turns per inch. Coil length is 12.7 cm (5 inches) with a diameter of 7.62 cm (3 inches). My present tuner model has a very low cost homemade coil wound on a very simple and sturdy air-core form. Since #12 bus wire was unavailable at the local surplus outlet, I wound the coil with #14 bus wire. The coil was fitted on the form shown in Fig. 3.

Please note that this coil size should allow its use with transmitters in the 150-Watt-output class. However, when using a helically-

wound antenna with this power, a capacity hat must be installed at the antenna top. This eliminates corona discharge which will damage the aerial at the top end.

Fig. 3 shows two pieces of acrylic plastic sheet 1/8 inch thick, .3175 cm, fitted as shown. All dimensions are listed in the drawing. Epoxy cement is applied at points where the sheets come together at right angles to each other. This gives rigidity to the coil form. The winding grooves are separated 4 mm apart. The slits in both pieces should have the same width as the thickness of the plastic sheet. That will allow a secure fit for the two pieces.

In wiring the tuner, I found that a common ground point return for the capacitors was important to efficient operation. Also, it would be a definite advantage to mount the tuner components so that they may be easily interchanged and interconnected in configurations other than the one described in this article. That will allow the tuner to be configured with any and all antennas the user will ever encounter. However, my particular design has been used with random wires of varied types and has worked well.

Operation

Initial tuner settings should be determined with the aid of an antenna noise bridge. The tuner will allow close to 1:1 swr match of antenna-to-rig output of 52 or 75 Ohms. Since the device tuning is sharp, great care must be taken in using regular tuning procedure to prevent overloading and damaging the final amplifier. If an antenna bridge is unavailable, the tuner may be initially set by tuning the device for maximum signal output on the receive portion of one's transceiver. However, on transmit, a slight retuning is generally necessary. This must be done with great care, again, to avoid overloading the final.

With transceivers that have a continuously variable power-output control, e.g., Ten-Tec's Century 21, the following procedure may be used: First, adjust the rig's power output for indication of swr below 1.5:1, e.g., start at 1.2:1. Then peak tuner capacitors for 1:1 output. Increase power a bit more. If swr rises above 1:1, repeak the input capacitor and/or output capacitor. If an swr higher than 1:1 persists, either or both coil taps have to be varied. The variation of coil inductance may be as simple as sliding the clip along the turn in a plus or minus direction, or the variation may have to be as much as a turn or two plus or minus.

By way of further illustration, let us say that we wish to tune up at 7.040 kHz. We will use either a noise bridge or the alternate method just described and the helical antenna. Proper match is achieved when the tuning coil is shorted from the input end of the coil to the fourth turn from the output end. The input capacitor is connected at the seventh turn from the output end of the coil. The input capacitor is meshed in at about 65% of total capacitance. The output capacitor is meshed in at somewhat less than 50% capacitance. With these settings, the antenna bridge will indicate a deep null. This is the indication of a properly matched antenna.

In moving from one end of the band to the other, settings of the tuner are sharp. This means that retuning of the matching device is usually necessary every 5 or 10 kHz to maintain swr down to 1:1. To make sure that power is indeed at the antenna, a fluorescent lamp is put at the aerial end without touching it. If the antenna is loaded, the lamp will glow. Use of this aid is necessary only when determining the tuner's true settings. It is a backup check in forestalling any false indication of power transfer from rig to antenna.

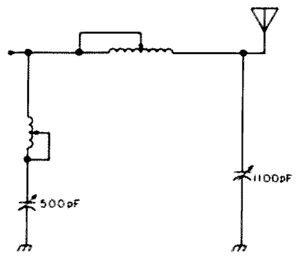


Fig. 1. Basic antenna-tuner circuit.

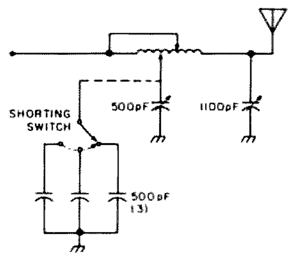

Fig. 2. Simplified antenna-tuner circuit.

Conclusion

Therefore, this tuner can match a rig to most any aerial and maintain an swr of 1:1. Because this antenna-matching device tunes sharply, additional harmonic filtering is available. The sharp-tuning feature is also evident on receiving; signals are peaked loudly and clearly. For those having capacitors in their parts box, the only other investment necessary is about 75¢ for scrap clear Lucite™ and one dollar for bus wire. When high-capacity condensers are unavailable, 365-pF capacitors with paralleled switched fixed condensers may be used.

The tuner design has been in service for many years, over 15 in all. One proof of its utility has been the longevity of the finals for my two rigs, one solid state, the other vacuum tube. The tubes are TV horizontal types. The transistors are 4-Watt types operated with a very short duty cycle at 20 to 35 Watts power output. The tuner capability in maintaining a 1:1 swr has greatly enhanced the life of the final amplifiers. ■

Cheap Power Ploy

This rugged supply will give you more power than you ever dreamed possible. Have we gone too far this time?

Looking for a 12-volt power supply of moderate current, I found a schematic and information that promised to be just what I needed. The supply was constructed following the guidelines and recommendations; upon completion, it was checked and put into service. Then the fun began.

The supply was essentially the same as shown in Fig. 1 and was to provide between 3 and 20 Amps output (peak) at 12 volts. It did indeed do this, but it also put out about 1/2 to 3/4 volts of assorted garbage that drove the equipment that it was operating into fits of sulking and, even worse, *almost* proper operation.

While some of the equipment that is designed for use with vehicular power sources is fairly immune to power-line noise, this is not the case with most dc-operated equipment. Spikes, ripple, and assorted other garbage can cause lost memories, lousy audio, and a host of other problems. It makes no sense to attach a kilobuck piece of gear to an inadequate supply.

The supply to be described here is the result of solving the problems of the original supply (Fig. 1). While the original was not designed for ham gear, the five supplies built to this pattern (Fig. 2) have proven excellent for everything from high-power stereo gear to allband transceivers.

The supply was designed to be built using parts that are cheap and readily available. The use of surplus components dictates a certain amount of caution but can result in an excellent product at a minimum price. With a little care and some improvisation with regard to transformers, the price of this supply should be under \$50.00—considerably under \$50.00 if you're a bargain hunter with a sharp eye.

What about specs? This supply will provide (depending on components chosen, of course) between 15 and 30 Amps (or more) at 5 to 28 volts with ripple and noise at about 5 to 10 mV p-p and regulation usually within .05 volts or so. There is full thermal protection and the usual provisions for current limit and OVP (over-voltage protection).

First, let's take a look at the supply in Fig. 1 and see where it goes wrong. Starting with T1, which provides 18 V ac to the bridge rectifier, and then to C1, which is 70k µF, we have about 25 V dc to the pass-regulator circuit under no-load conditions. The regulator and pass transistors require a voltage at

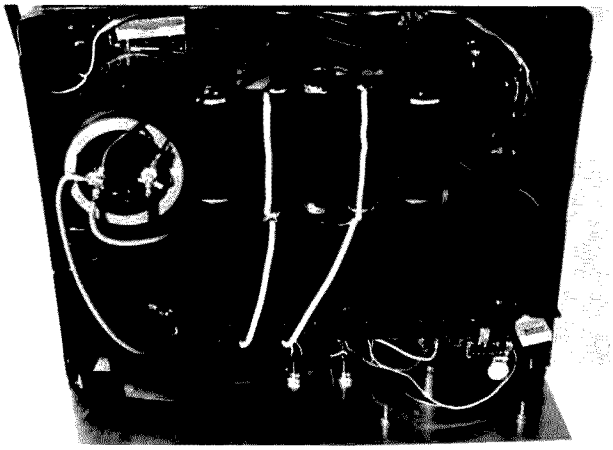

Photo A. Interior of 25-Amp supply showing position of major components and airflow shrouding.

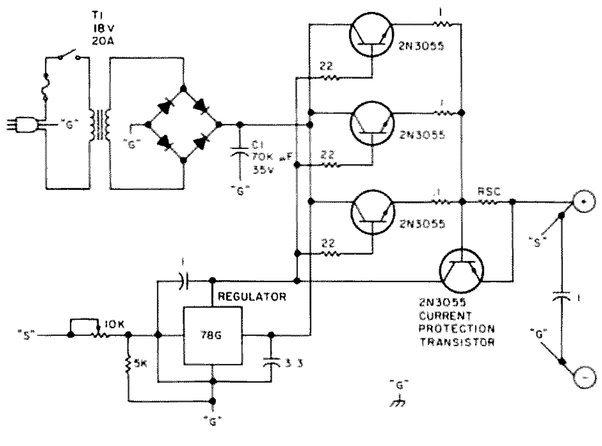

Fig. 1. Original supply.

least 5.6 higher than the output voltage to maintain regulation 13.6 V + 5.6 V = 19.2 V. If at any time the input voltage drops below 19.2 volts, the regulator loses control and the output changes.

The voltage across C1 has a waveform as shown in Fig. 3. As the current increases, the hump at the front increases. This is the principle component of the output ripple and is due to the fact that the rectifiers conduct for a short period of time to charge the capacitor. Increasing the capacitance simply increases the amplitude of this "spike," which makes the problem worse and increases the already high demands on the diodes in the bridge.

In addition, the regulator was unstable at certain currents and seemed to put out more hash than the spec sheet called for at this voltage (about 10 times more!). Bypassing and rewiring the ground circuit got rid of the hash, and increasing the input voltage improved the regulation and ripple problems. The supply proved OK for a 2-meter amp that didn't seem to care about the ripple (.2 V at 20 A), but it wouldn't serve the purpose it was originally built to serve.

At this point, I priced commercial supplies and immediately went back to the drawing board. After some research and experimentation, the supply shown in Fig. 2 was built and tested. It worked. The four supplies built to the same pattern have all worked.

The belt-and-suspenders approach has proven to be well worth the time and slight additional cost. Actually, with the price of 2N3055s at three for a buck and the use of smaller and cheaper capacitors in what is really a simple circuit, the actual cost was not much more than the original supply.

Let's now see the how and why of the "quiet" supply. The bridge rectifier uses surplus diodes rated at 100 V and 50 Amps; this seems like overkill and perhaps it is, but the peace of mind bought for $1.25 each was worth it. With C1 at 25k μF, the conduction spikes can get up to ten times the output current, so they really don't represent that much overkill after all. C1 is 25k μF at 75 volts because I got a box full for $1.00 each. R1 is simply a bleeder and should draw about 100 mA at the peak no-load voltage across C1.

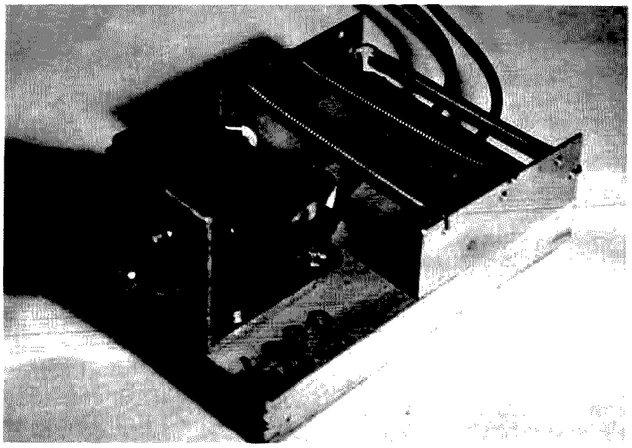

Photo B. Load resistor for testing.

T1–T4, ZD1, R2, and C5 form a circuit that thinks it is a multi-farad capacitor. The capacitance of C2 is multiplied by the beta of the Darlington circuit formed by T1–T4. The current demands on T4 are not enough to require a 3055, but they're cheap. I simply selected one with a beta of about 60 for the driver. This particular circuit is about 10 *farads* effective capacitance and the output ripple to the regulator is less than .2 volts at 20 Amps (p-p). ZD1 provides a clamp to keep the input voltage to the regulator at 24 volts in this case.

The regulator circuit is based on the 78G (or 78MG) because I like it. It is a good, flexible chip that is protected four ways from Sunday, and it is cheap.

The 78G will provide over one Amp of output, with the average beta of a 2N3055 at 40 or so. The circuit should be good for 40 Amps. Actu-

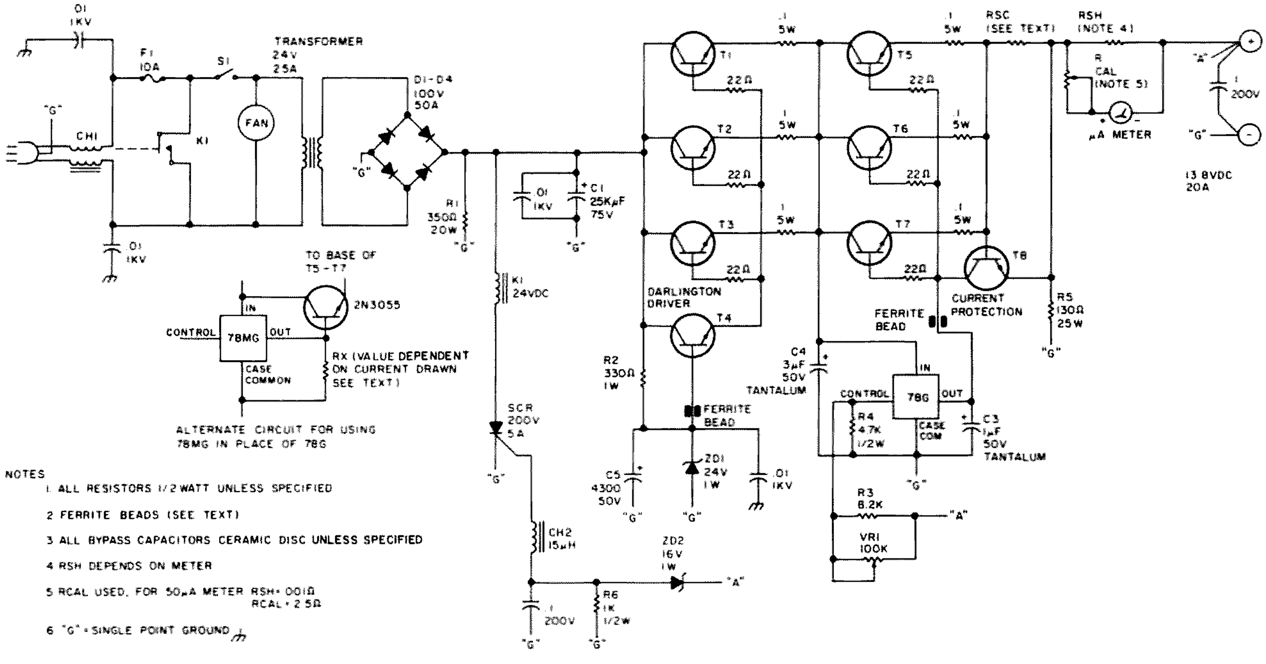

Fig. 2. Schematic (all transistors are 2N3055).

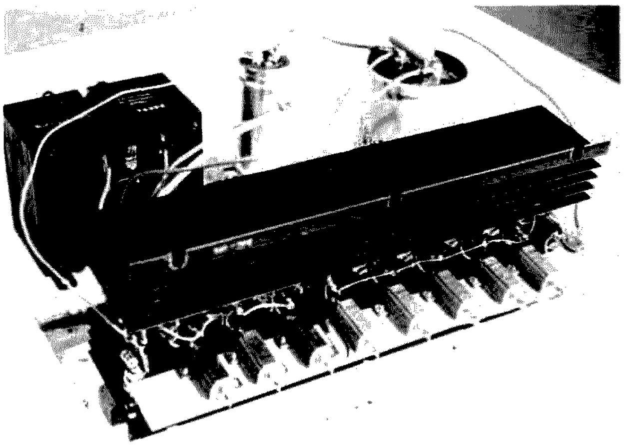

Photo C. 25-Amp supply on the breadboard.

ally, above 25 Amps or so, the use of the Darlington circuit is a good idea. When using the 78MG, the Darlington circuit *must* be used. When using the Darlington circuit, the current demands are so small that the chip may need the slight load, RX. This value will depend on the individual chip and is usually 300 Ohms to 1k Ohms for a 13.5-V supply.

R3, R4, and VR1 set the output voltage. R3 is used to set the maximum voltage and VR1 trims this to the desired lower output voltage. With R3 at 8.2k and VR1 at 100k, this will be about 14 V maximum. The connection point for R3 should be at the output connector or, if remote sensing is needed, it can go to the remote sense point. The resistors shown in the base and emitter leads of the pass transistors are absolutely necessary. They prevent one transistor from hogging all the current. The base resistors are not particularly critical as to value, and 10 to 22 Ohms will do fine (all the same value, of course). The emitter resistors should be about .1 Ohms and 5 to 10 Watts, depending on supply voltage, current, and the number of pass transistors.

The number of pass transistors required will depend on several factors, the most important being the desired output current of the supply.

The 2N3055 is rated at 15 Amps and 117 Watts (TO-3 case) at 25° C. Expecting one to provide both at the same time is an invitation to disaster, especially with surplus components.

Let's take a realistic look at what the requirements will be for this supply providing 13.6 volts at the 20-Amp level. The regulator will need approximately 6 volts to work properly, so under a 20-Amp load it will have to dissipate about 120 Watts. The capacitor multiplier at 20 Amps will need about 5 or 6 volts, so we now have 240 Watts at full current. This has to be dissipated as heat via the heat sink and is one good reason for derating the transistors. Derating surplus transistors to 8 Amps (or preferably less) and 50 or 60 Watts will make for a longer life and lessen the chance of catastrophic failure.

The output resistor, R5, provides a constant minimum load for the supply and helps with stability (100 mA or so will be adequate—130 Ohms for the 13.6-volt supply).

If you look at the circuit and remember your solid-state basics, it can easily be seen that we have an amplifier with quite a bit of gain. Certain steps must be taken to ensure stable operation and to prevent amplification of unwanted signals. As Elmer used to tell me, "Build it like you mean it." In this case it means bypassing everything, especially the 78G. All those G points on the schematic mean that all grounds are brought to a single point on the chassis. More about this during the mechanics discussion. The ac line should be filtered and bypassed, and the case should be rf tight, in this case to keep it out rather than in. Ferrite beads on the base leads of the Darlington driver(s) are not a frill if powering VHF equipment is contemplated.

The heat sink used is one that seems to be common on the surplus market. The ones that I bought came with four TO-3 transistors and miscellaneous parts and cost about $3.00 each. The heat sink is 12" × 4" × 2.5" with 10 fins for a total radiating area of 600 square inches. All of the hot parts are mounted on the heat sink using aluminum stock, as shown in the photos. The bridge can be mounted on its own sink or on an extension bolted to the pass sink. A muffin fan (105 cubic feet per minute) provides cooling, with cardboard shrouding to direct the air flow through the heat sink. The 78G is mounted on the end of the heat sink farthest from the fan at the hottest point. If thermal limits are exceeded, it shuts down the pass transistors. Many home-built supplies fail to take advantage of this feature which is built into most regulator chips. This is an oversight that can prove costly.

Construction/Mechanics/ Testing Options

This supply is a definite breadboard project and should be approached as such (by the way, sink cut-outs make fancy, cheap breadboards). I prefer TO-3 devices, used with sockets.

Photo D. Heat-sink assembly for 20-Amp supply.

Fig. 3.

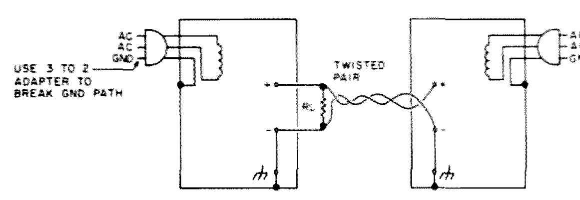

Fig. 4.

Whatever package style you use, special care should be taken in mounting. All burrs should be removed and the best-possible contact between the device and the heat sink must be ensured. This means using heat-conducting compound on all devices. As you install each device, verify that there are no shorts to the heat sink. The precision emitter resistors that I used were hamfest specials, but the ceramic ones available at most parts houses will serve as well. Use #10 or #12 wire for the collector and emitter buses. I simply stripped out some scraps of Romex left over from rewiring the shack. The main run wiring used was #10 or #8 THHN wire scrounged from an electrical contractor's scrap box.

The heat sink is at ground potential but is insulated from the case. Grounding is accomplished by running a single wire from the common connection of the 78G (the 78G is *not* insulated from the sink) to the ground common point. *All* ground connections are brought to the common point, using heavy wire that is as short as possible. The lines from the capacitors, the rectifier, the negative output post, and the ac-line ground conductor are connected to this point. This prevents ground loops and helps to keep the output clean.

Cardboard shrouds are used to focus the air flow through the sink and provide for efficient use of the cooling air. The case should be well ventilated. Transmitter techniques can be used for rf proofing. All of the usual transformer tricks can be used for your supply: buck/boost, series, parallel, etc. I do have a couple of suggestions that might prove handy.

First, there are available surplus small transformers that provide 2 volts or so at up to 30 Amps (Fair Radio is one source). These are great when the "main" transformer is just a bit low.

Second, an often-overlooked source for high-current transformers is gas stations. Really! Those old Tungar bulb chargers had some bodacious transformers in them with multi-tap primaries and secondaries. Many times they can be had for hauling them off. (Take help!) Newer ones also are available after the selenium bridges have blown. Those with aluminum secondaries will need some of the special grease for making good connections to aluminum wire. If you're using the supply to power an SSB rig or for other low-duty-cycle applications, you can push the transformer current ratings a bit, but it is best to have a bit of reserve for good dynamic performance.

Protection circuitry is an absolute must for this supply if used with voltage-sensitive equipment. Any of the popular OVP circuits may be used; the one used here crowbars the ac line using a simple circuit that costs less than a single high-current thyristor.

Current limiting is nice also; the circuit used here is a common one and performs quite well. Rsc is set for a .7-volt drop at the desired current level. At this point the voltage will drop to hold the output current at this level. Rsc can be built up by paralleling standard values. Rsc should be in the airstream to keep it cool. The choke and capacitor on the gate of the SCR keep garbage on the line from causing false firing. Switching high-current loads can cause this type of transient. (I blew a few fuses before I figured that one out.)

This supply should be breadboarded and tested before final construction. This is not a complicated process, and it will pay dividends when the supply is put to use. As with any homebrew project, you are spending time rather than money. This is time well spent.

The first step is to assemble the heat sink with all its components. Then a simple test to determine the necessary I/O differential voltage is needed. With a sensitive DVM and a light load on the output, vary the input voltage until the output drops an mV or so. This is the voltage which must be supplied to the pass circuit to maintain regulation. You now know the necessary voltage that the transformer must supply under full load for proper operation.

To test the supply under load, you will need a load resistor (see photo). One is made by paralleling several short pieces of nichrome heating coil. (I got 10 feet for $3.00 at the local electrical-supply house.) By adding more pieces in parallel, the current increases. If you didn't build an ammeter into the supply, a 7-7/16" length

Parts List

Note: This supply was designed to take advantage of surplus parts. Therefore, the prices listed will be dependent on the source and availability of each item.

All bypass capacitors are ceramic disc unless otherwise specified.
All resistors are ½ Watt unless otherwise specified.

Bypass—.01, 1-kV disc, 4 @ .25 ea.	$1.00
Bypass—.1, 200-V disc, 2 @ .25 ea.	.50
K1—relay, 24-V-dc coil, 3PDT, all contacts in parallel	1.50
Fan—105 cfm muffin-type fan	7.50
Xfmr—any combination of transformers supplying the necessary voltage and current may be used. The surplus xfmr used in Fig. 2 was 24 volts @ 25 Amps.	18.00
D1-D4—100 V @ 50 A used in this supply, 4 @ $1.25 ea.	5.00
C1—25,000 µF @ 75 V	1.00
Cs—4300 µF @ 50 V	.39
C3—1 µF @ 50 V tantalum capacitor	.39
C4—3 µF @ 50 V tantalum capacitor	.39
Resistors:	
R1—350 Ohms, 20 W	.39
RC5—130 Ohms, 25 W	.39
R2—330 Ohms, 1 W	.15
R3—8200 Ohms, ½ W	.05
R4—4700 Ohms, ½ W	.05
R6—1000 Ohms, ½ W	.05
Base resistors—22 Ohms, ½ Watt, 6 @ .05 ea.	.30
Emitter resistors—.1 Ohms, 5 Watts, 6 @ .35 ea.	2.10
VR1—100k-Ohm trimpot	.49
Rsc—current limit, see text	
Rsh and Rcal depend on meter used. For 50-uA meter used in Fig. 2, Rsh was .001 Ohms, and Rcal 2.5k-Ohm trimpot.	
Transistors—2N3055, 8 @ .33 ea.	2.64
SCR—200 V @ 5 Amps used here	.29
ZD1—24-V, 1-Watt zener diode	.24
ZD2—value depends on OVP desired. (16 V used for 13.8-V supply)	2.64
78G—Voltage regulator	2.95
CH1—14 bifilar turns #14 wire on ferrite rod approx. ½" diameter, 4½" length	2.00
CH2—surplus 15-mH choke	.25
S1—15-Amps @ 120 V toggle switch	1.49
F1—10-Amp fuse in clip-type holder.	1.25
Heat sink—surplus 2½" × 4" × 12"	4.50
Meter—50 uA used in Fig. 2 supply, surplus	3.00

Misc. case, hardware, aluminum stock, suitable wire (see text). The case shown in the photos is 5" × 12" × 15" and was purchased at a hamfest for $1.00.

Substitution: Since this project is designed to use surplus components, reasonable substitutions are to be expected. When surplus components are used, derating should be the rule. C3 and C4 must be tantalum capacitors for proper operation. The resistors used at R1 and R5 should be capable of dissipating at least twice the I × E power for safety and stability.

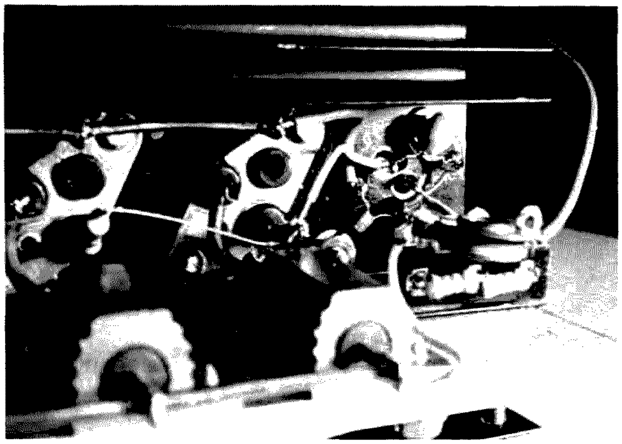

Photo E. Detailed view of 78G wiring (note short leads on bypass).

of #12 wire will serve as a shunt, providing 1 mV per Amp. Using the setup shown in Fig. 4, look at the output under load. The setup prevents ac ground loops from showing up as false noise on the scope. If the scope is not more sensitive than .01 V per cm, the trace should barely widen under full load. Check at several output levels. If you have inordinate noise, make sure the setup is right before troubleshooting. At the current-limit level, using the circuit shown, there will be a large increase in ripple—this is normal. If Rsc needs to be lowered, it can be paralleled with additional resistors.

If the output behaves up to a certain current level and then falls off, more input voltage may be necessary. When testing the supply on the breadboard without the fan, the heat sink gets hot quickly—caution! If it gets too hot, the 78G will shut down until things cool off. If you have high-frequency hash, it may be necessary to add .01 discs to the input and output of the 78G. In stubborn cases, you may have to change the layout around the 78G. If the supply is unstable at some current levels and stable at others (higher), you may have a ground-loop problem. Try changing the lengths of ground leads and if you're using the Darlington circuit for the regulator pass, try decreasing the value of RX.

One of the supplies that I constructed is variable from 5 to 20 volts (VR1 on the front panel and a switch to use all or part of the secondary) at 20 Amps. It has proven to be one of the most often used bench tools I have. Another smaller (12 V at 15 A) supply provides the dc for a TV-studio installation. This supply is, of course, a compromise; you pay back in lack of efficiency for a clean stable output. "Build it like you mean it," and it should provide you with a long trouble-free performance—quietly. ■

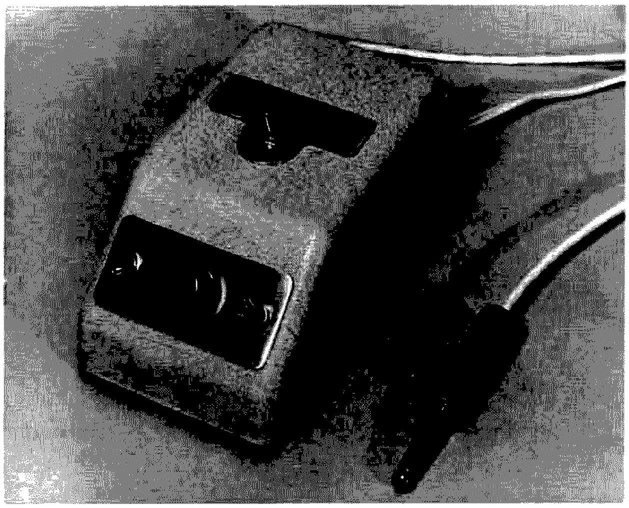
Penn's Two-Tone Gadget

Clue one: We're talking about lab quality.
Clue two: Get your junk box.

Here's a professional-quality two-tone tester designed for easy duplication. Using no precision parts and having only two easily set internal adjustments, it generates sine waves with less than 0.1% total harmonic distortion. This inexpensive project can be built with all new Radio Shack components for $30 to $40. The cost can be reduced significantly if you use a battery for power and your junk box for some of the parts. It's sure to be a valuable addition to your collection of test gear.

If you've ever repaired or tested an SSB transmitter, then you've used or needed a two-tone test oscillator. A dependable source of high-quality sine waves, the oscillator can be used for any number of transmitter tests. Typical applications include checking circuit gains, peaking tuned stages, adjusting phasing exciters, checking or setting ALC thresholds, and measuring amplifier linearity.

Photos by W1GSL



Small enough to be out of the way, this neat unit is big on quality and convenience.

Unfortunately, many of the published two-tone circuits are of limited use because the output waveform is not pure enough for some tests. A good linear amplifier, for example, will have odd-order intermodulation products 35 to 40 dB down from the desired output. Obviously, the two tones used to measure such performance should be at least that good when they go in the microphone jack. Minus 40 dB is only 1% distortion though, and many testers are incapable of generating waveforms that pure.

The published circuits which do provide sufficient audio purity often attain it through the use of sharp audio filters. Those filters require either high-quality components or several circuit trims to keep them on the right frequency. Precision parts work fine but are difficult to find and expensive to buy. Lower-quality components need to be selected or trimmed and even then may drift enough to require frequent readjustment.

The oscillator described here has a number of features making it a better choice for the amateur test bench:

- All distortion products are at least 60 dB (typically 65 to 70 dB) below the primary output. That's good enough for taking even a hard look at state-of-the-art equipment.
- The unit can be duplicated using everyday parts (5% resistors and 20% capacitors) because purity has been achieved by careful oscillator design and not heavy filtering.
- Unlike most commercial equipment, this unit is physically small, rugged, and well shielded. When you need it, it works; when you don't, it isn't in the way.
- The box plugs right into the transmitter microphone jack and includes a handy

switch for keying the transmitter. The adjustable (1 vrms maximum) audio output is sufficient for driving rigs having either high or low impedance inputs.

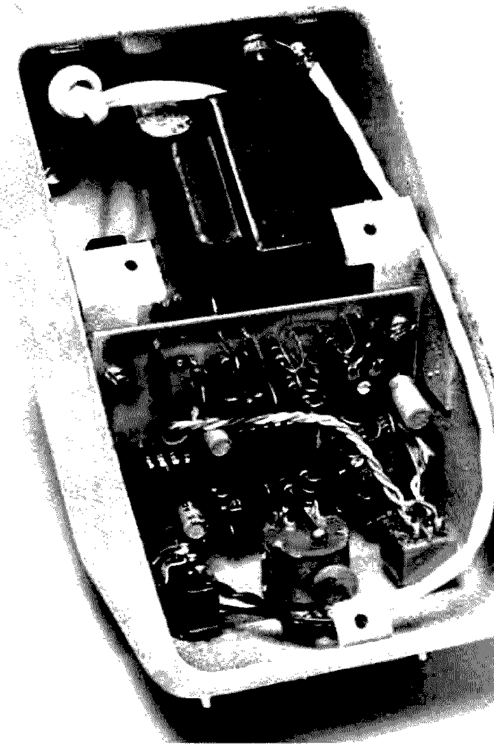
- Power drain is only 12 mA at 9 volts, so you can run the unit from a single 9-volt battery and not worry about limited battery life.

The Circuit

The two oscillators are designed around an LM324 quad op amp as shown in Fig. 1. Each oscillator is followed by a simple peaked low-pass filter and the two signals are combined in the 741 output amplifier. Switching is provided for selecting either or both tones and the output level is adjustable over two ranges covering 0 to .18 and 0 to 1 volt rms.

The identical oscillators are carefully considered versions of the classic Wien Bridge oscillator circuit (see the sidebar, "On the Trail of the Wien Bridge," elsewhere in this article). The sine waves produced by these oscillators have only about 0.5% distortion. The frequency of oscillation is determined by four components: the series capacitor and resistor between the op amp's output and its non-inverting input terminal, and the parallel capacitor and resistor between there and ground. The oscillation frequencies with the components specified in Fig. 1 are 500 and 1750 Hz (not the 440 and 1600 Hz labeled on the photographed unit).

The remaining components in the oscillator circuit provide dc biasing and set the loop gain to unity. The trim resistor is used to adjust the small signal gain a little higher than required to sustain oscillation, and then the diodes and 470k resistor in the feedback path reduce the gain by 10% when the output signal grows larger than about 1 volt peak to peak. Overall



The 9-volt power supply takes up most of the room inside. Current drain is only 12.5 mA, so battery operation is an attractive space- and money-saving option.

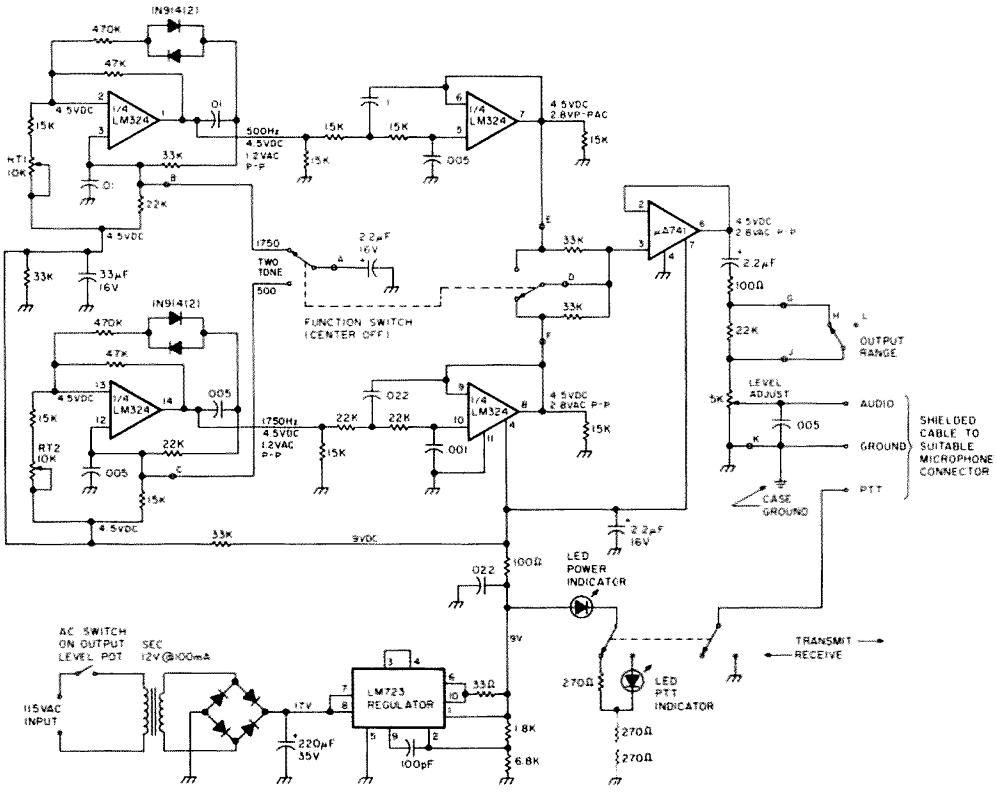


Fig. 1. Two-tone oscillator schematic. Resistors are ¼ W, 5%. Letters shown where wires leave PC board (see Fig. 3).

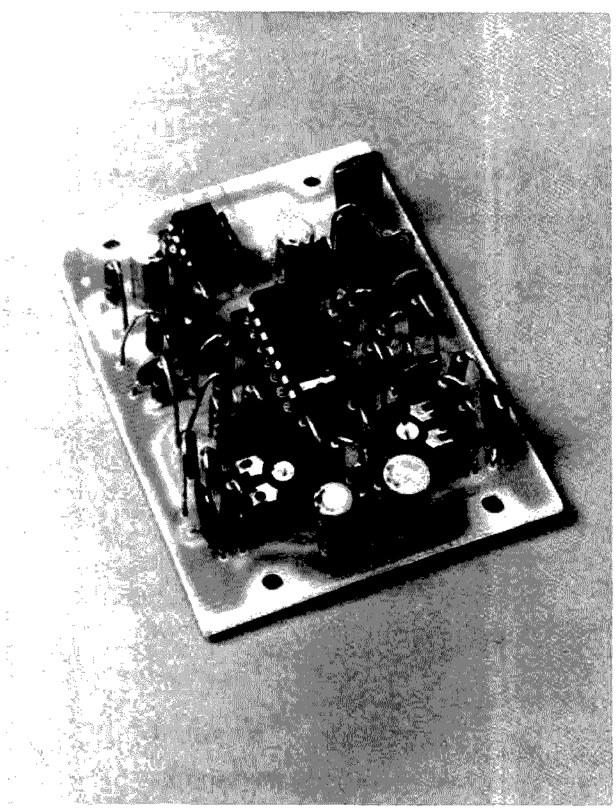

Standing components on end lets everything fit on the 2" by 2.7" PC board. More real estate might be necessary if you build with perf or prototyping board.

distortion is low because even this relatively minor gain reduction is applied gently as the diodes turn on.

The distortion introduced by this type of gain control is mostly at the third harmonic of the oscillation frequency. An additional 5-dB reduction of that component is realized by driving the diodes and 470k resistor from a point after the feedback capacitor instead of directly from the amplifier output as is usually the case. Even with this change, the third harmonic signal is still some 10 dB higher than the second harmonic. In a sense, this is desirable because the third-harmonic energy, being farther from the fundamental frequency, is easier to filter off.

The oscillator outputs are dc-biased to half the supply voltage by a simple resistive voltage divider. That step maximizes the output ac level possible before the amplifiers saturate. Each section of the quad amplifier is also dc-loaded with a 15k resistor. The load resistor prevents crossover distortion by forcing the rather simple LM324 output circuit to operate strictly as a class-A amplifier.

One design goal for this project was to have all undesired frequency components at least 60 dB below the primary outputs. To achieve this, the oscillators are followed by low-pass active filters. Since the oscillator outputs are so clean, this goal can be reached with only a small amount of filtering. That's significant because it means the filter stages don't have to be held to tight frequency tolerance and so won't require precision parts. The filters have a gain of one at dc and a peak ac gain of 2.25.

The dc gain causes the filter output to copy the oscillator biasing at half the supply voltage. The ac gain ensures that with overdrive the filter output will begin clipping before the oscillator output does. If the oscillator could somehow saturate first, it might be possible for the misadjustment to go unnoticed because the filter would tend to hide the evidence. Another benefit of having gain in the filter stage is that the oscillator output level can be lowered. That reduces distortion because the feedback diodes don't get turned on as fully as they would at the higher signal level.

The outputs of the two low-pass filters are combined in a 741 amplifier which in turn is ac-coupled to the output attenuator. The 741 does not need the 15k load resistor because its sophisticated output circuit doesn't have the distortion problems of the simpler LM324.

After passing through the output-level control, the audio leaves the box in a shielded cable it shares with the push-to-talk line. The microphone plug on the end of this short cable should match the transmit-

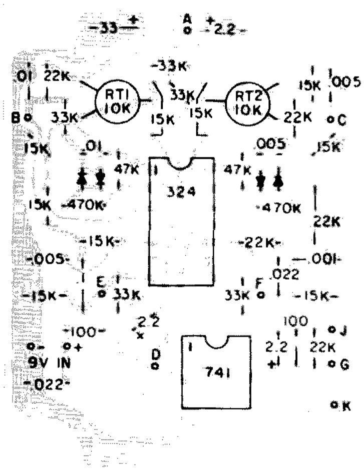

Fig. 3. Component placement (from the top side of the board).

ON THE TRAIL OF THE WIEN BRIDGE
Selecting a Good Oscillator

There's certainly no shortage of published audio-oscillator circuits, but finding the right one for this two-tone tester wasn't easy. The requirements (low distortion, simplicity, low power consumption, and reliability) seem common enough, but the circuits usually recommended for the task all had flaws rarely mentioned in the literature. Mostly those flaws involved the means chosen to control the oscillator gain.

An oscillator is really an amplifier around which has been placed some frequency-sensitive positive feedback. The combination of amplifier gain and feedback attenuation is called *loop gain*, and at the frequency of oscillation, the loop gain is *exactly* one and has *exactly* zero phase shift. That's another way of saying that the signal presented to the input of the amplifier is precisely the one needed to produce an output which will come back through the feedback network to reproduce itself. The phase shift across the feedback circuit is frequency-sensitive, so any departure from zero loop phase can be corrected by a change in the oscillation frequency. Unfortunately, any departure from the desired amplifier gain is a little harder to accommodate.

Since real-world components are imperfect, we can't simply specify parts that give the magical gain of one, but we can design in circuit features which will automatically adjust the gain for us. The easiest thing to employ is the most widely used: saturation. Saturation, or peak clipping, is what happens when an amplifier is asked to produce more output than it possibly can. Gain is defined as the ratio of output to input, and as saturation occurs, the effective gain must drop since the output amplitude remains nearly constant while the input drive increases. Saturation clearly introduces distortion and most simple sine-wave oscillators have distortion in the 5-to-15% range because they depend on saturation effects to maintain the loop gain at unity.

Modern laboratory oscillators usually achieve low distortion by using sophisticated agc circuits to regulate gain. Early equipment did the same thing by the clever use of a nonlinear component: the tungsten filament of a common panel lamp. The resistance of the bulb filament goes up as the average current through the lamp increases, and very good gain control can be had by the proper application of that effect. The classic lamp-stabilized Wien Bridge oscillator is a very elegant circuit capable of producing extremely pure sine waves. It was devised in the 1930s, in part by a young engineer named William Hewlett who later formed a company with his friend David Packard to manufacture the oscillator.

The modem version of that circuit, shown in Fig. A, is reproduced in almost every text discussing audio oscillators. The light bulb is driven with a signal proportional to the oscillator's output. The filament resistance averages that output over several tenths of a second and so controls the oscillator gain to exactly one. Oscillator distortion may be as low as .01%.

Unfortunately, the thermal properties of the lamp filament introduce a tendency for the output amplitude to ring at a frequency near 10 Hz. This secondary oscillation can be started by the slightest circuit disturbance and may take 10 or 15 seconds to decay away. The commonly available lamps used in this circuit also require more drive voltage than a 9-volt battery provides. Moreover, the circuit needs 15 to 20 mA of supply current per oscillator and that seems excessive for a battery-powered unit which doesn't really have to deliver any output power. Together, these several considerations make the circuit of Fig. A undesirable for this project despite its excellent output waveform.

The next commonly recommended circuit, shown In Fig. B, is usually offered as a modern replacement for the classic arrangement because it uses a JFET as the variable resistor instead of a light bulb. Unfortunately, a JFET does not make a good resistor since its resistance varies with the drain-to-source voltage as well as the gate-to-source bias. That means the resistance will be changing during each oscillation cycle, and the changing gain that causes leads to problems. Distortion was a terrible 5 to 10% with the several circuits I tried. The variations published most often were the poorest performers because the zener diodes in the output-level detector *guaranteed* the FET would be operated outside its linear range!

The circuit type finally selected is shown in Fig. C. Diodes are used in the feedback path to switch in a resistor and lower the gain as the output amplitude Increases. This scheme will introduce some distortion because the amplifier gain is changing during every oscillation cycle. Only a slight gain change is needed, however, and the overall distortion at the oscillator output can be kept well below 1%. The final circuit design was optimized for the IC used and generates a sine wave having only 0.5% distortion. As a bonus, the unwanted energy is primarily in the third harmonic where it is relatively easy to filter out.

Fig. B.

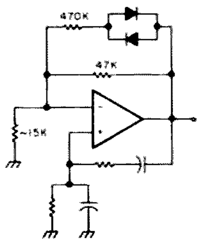

Fig. C.

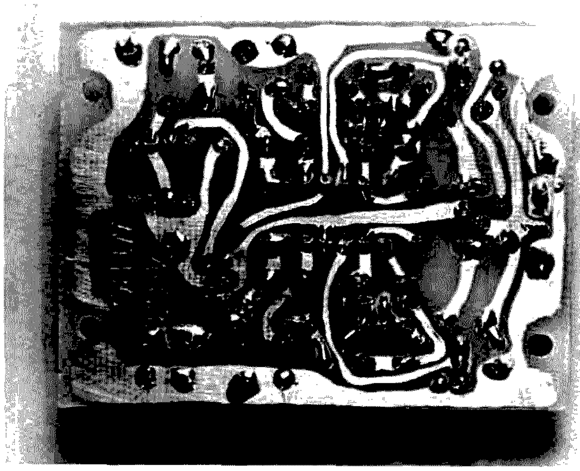
ter's input jack. The stereo phone plug shown in the photographs fits many older pieces of gear (standard wiring; PTT line to tip, audio to ring, ground to sleeve), but newer equipment may require a different type of connector.

The two-section frequency-select switch turns the oscillators on and off and also introduces a gain of ½ between the active filters and output amplifier during two-tone operation. This attenuator prevents the peak audio output from doubling when both oscillators are on. That convenient feature makes it unnecessary to adjust the transmitter drive level when switching between single- and two-tone tests.

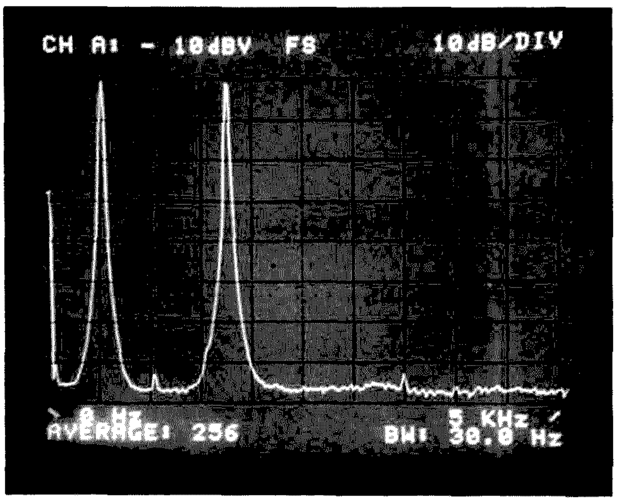
The power supply is a simple rectifier-filter followed by an LM723 regulator set to hold the output at 9 volts. Any dc output voltage from 8 to 20 will power the oscillator; the 9-volt level was chosen to make sure the circuit would work with a battery supply. Two LEDs are used as front-



My PC pattern was painted on using nail polish as resist material. While not as pretty as the photographic copy you can make from Fig. 2, it works just as well.

panel status indicators. One comes on with the dc power and the other lights when the PTT switch is in the transmit position. Wired in series to conserve current, the LEDs at 10 mA still draw 4 times the current needed by the rest of the circuit!

There are several reasons to consider using a battery instead of the ac supply. The transformer supply is convenient but bulky. My supply takes up more room than the rest of the circuit even though the transformer is smaller than any available from Radio Shack. Using the smaller 9-volt radio battery will definitely widen the choice of enclosures suitable for housing the tester. The battery will last a long time since the circuit only draws about 12.5 mA. If you do decide to build in an ac supply, try to get a shielded transformer like the one in the photographs. Failing that, be sure to mount the transformer further from the audio circuits than I did to keep 60-Hz hum off the audio signal.



Proof of the pudding! The two-tone output as seen on an HP 3582A spectrum analyzer. Horizontal scale reaches from dc to 5 kHz, and at 10 dB per vertical division, the largest spurs are 70 dB below the tone peaks. The "signal" at dc is generated inside the analyzer.

Another alternative is to build the ac supply with a surplus wall-mount transformer of the type used to power calculators. Even a 3- or 6-volt transformer could be used with a voltage-multiplying rectifier circuit. The LM723 regulator will work with any dc input between 12 and 40 volts, so a suitable transformer shouldn't be hard to find.

Parts

The audio circuits and PC board were carefully designed to use component values available from Radio Shack. Of course, a considerable savings can be realized by scrounging parts from old transistor radios. The capacitors in particular should be easy to locate. The four electrolytics on the PC board are quite common values but could be replaced with units having from 1 to 4 times the capacitance. The smaller capacitors used in the oscillators and filters must be the values specified but are still easy to find on old circuit boards. If you have a choice, stay away from ordinary ceramic capacitors since they're often not as stable as other types. The circuits are relatively insensitive to drift and the ceramic parts will work acceptably, but they should not be your first pick if something else is available.

The two trim resistors should probably be purchased since physical sizes vary widely and the PC layout is tailored to the Radio Shack parts. While not strictly necessary, the use of IC sockets is recommended as they greatly simplify amplifier replacement should the need arise. The switches can be of any size and type which fit the box used for the project.

Construction

The entire oscillator/amplifier portion of this project is built on the single 2" by 2.7" circuit board shown in the photographs and Fig. 2. The printed circuit makes it easy to pack a lot of components neatly into that small space. Point-to-point wiring on a slightly larger piece of prototype perfboard will work just as well if you're so inclined.

My power supply was built on another bit of PC board. That board also provides mounting space for the two indicator LEDs and the push-to-talk switch. The power supply has so few components that designing your own layout shouldn't be a problem. I haven't included the pattern for my board since you surely won't have the same size transformer or project case that I used.

The cabinet itself is the steel transformer housing from a discarded high-intensity lamp. Recycling old enclosures from unusual sources adds an extra bit of fun to home-brew projects and can provide some really custom-looking results as well. In this case, the old scratched-up paint was removed and replaced with a fresh coat of black wrinkle which was in turn oversprayed with light blue. Legend plates of a contrasting color add to the nice appearance, provide a flat surface for the transfer lettering, and also cover up the original holes.

If you want to use a commercially available box, Radio Shack sells several that are suitable. The choice is particularly wide if a battery is used instead of the larger ac-operated supply. Be careful not to buy a plastic box as the lack of rf shielding is an invitation to trouble.

The printed circuit board is a lot easier to make than you might think. If you have access to photographic

equipment, you can turn out a really professional board using the pattern of Fig. 2. Otherwise you can do what I did and get perfectly acceptable results using fingernail polish as resist material.

The pattern in Fig. 2 is full size and the holes are all on 0.1-inch centers. Drilling the holes is easy using a piece of 0.1-inch-spaced perfboard as a template. Cut out the pattern (or a Xerox® copy of it) and carefully glue it onto a piece of perfboard so the holes in the PC pattern align with those in the board.

Now cut out an unetched blank of PC board and clamp the drilling template to the copper side. Drill the four mounting holes first. I used a #33 drill for 4-40 screw clearance; a #28 drill is the one to use for 6-28 hardware if you prefer that size. Loosen the clamps and bolt the boards together using those four holes.

Now you're all set to drill the 122 component holes. A #60 drill is necessary for this and a drill press helps a great deal. The holes in the perfboard force you to drill in the right place; when the boards are unbolted, there'll be an impressively neat array of properly-spaced holes. Sand the copper lightly to remove any rough edges and you're all set to apply the resist pattern.

The pattern of printed circuit runs is simply painted onto the copper surface with nail polish using Fig. 2 and the drilled holes in the board as a guide. Choose a bright red color so the resist will be easy to see against the copper surface. Applying the nail polish with the brush attached to the lid of the jar is easier once about 2/3 of the bristles have been trimmed away with a sharp pair of scissors. Small mistakes with the polish can be scraped off with a pointed knife blade. Really big mistakes can be corrected by cleaning off the entire board with nail-polish remover or a solvent like acetone. *Acetone is serious stuff, so use good ventilation, avoid excess skin contact, and don't work near open flames!*

After the resist is applied, the board can be processed using any of the standard techniques described in the *ARRL Handbook* and elsewhere. Check your work for stray resist material joining runs before dropping it into the bath. When it's done, wash the board with water and examine it for any traces of unetched copper before removing the resist. As a final step after cleaning off the nail polish, run over the board with fine sandpaper or a pencil eraser to brighten up the copper in preparation for soldering.

Mounting the components takes just a few minutes once the PC board is ready. The holes for the two trimpots will have to be drilled out slightly to receive the mounting pins, and that should be done before anything is soldered down. Placement of the various parts is shown in Fig. 3 and the photographs, but if there is any question, the PC patterns can always be checked against the schematic.

The PC pattern in Fig. 2 does not exactly match the board in the photographs. In my unit, the 100-Ohm resistor in series with the 741 output is mounted on the output-level switch. Without that resistor, the 741 oscillates at 2 MHz when the controls are set for maximum output. That happens because the .005-uF bypass capacitor is then effectively connected directly across the op-amp output and it loads the output stage at high frequencies. The problem wasn't noted until after my board was etched, but the resistor cure is included in the Fig. 2 layout.

Parts List

*Items so marked are used in the power supply and may be deleted if power is obtained from a 9-V battery. Suitable components are available from Radio Shack and elsewhere. Several parts are identified with Radio Shack part numbers to better describe the components needed.

Resistors

Value	**# Needed**	
* 33 Ohms	1

- * LM723 voltage regulator
- LM324 quad op amp
- 741 op amp
- * 100 PIV, 1 Amp or more bridge rectifier RS #276-1171
- LEDs (2 required)
- 1N914 small signal diodes (4 required)

Miscellaneous

- * Power transformer
- DPDT (center-off) toggle switch RS #275-1545
- SPST switch
- IC sockets
- PC or prototype board
- Cabinet
- Mike plug
- * Line cord

Checkout

The board should be checked before final assembly into the cabinet. Temporarily solder on the switches with short lengths of wire and connect a scope or ac voltmeter to the output terminal. Hook a 9-volt supply to the power-input pad and ground and verify that the circuit draws about 2.5 mA. Now set the output attenuator to the high range (22k resistor shorted), flip the mode switch to the 500-Hz position, and adjust RT1 until the output level is exactly 1 volt rms (2.8 volts p-p on the scope). Then switch the mode switch to the 1750 position and adjust RT2 to give the same reading. When both tones are on, the output will read 0.7 rms, but the peak-to-peak level will still be 2.8 volts.

If the circuit doesn't work straight away, check the mode-switch wiring and the amplifier dc output levels. It's unlikely that you made a major PC board error, but solder splashes or stray whiskers of unetched copper are always a possi-

bility. Several strategic voltage levels are shown on the schematic for help in troubleshooting. The ac levels will change with trimpot settings and in any case must be measured with an ac-coupled voltmeter. The ac-voltage ranges of most VOMs will respond to either ac or dc voltages. That problem is easily cured by placing a 2-to-30-uF capacitor in series with the meter. The dc voltages noticed should be independent of switch or trimpot settings, as the dc bias on the amplifiers is determined only by the power-supply level.

Putting It All Together

One disadvantage of working with high-purity signals is that they are so easily corrupted by poor assembly practices. Hum levels unobjectionable in other applications can significantly compromise the quality so carefully designed into this circuit. Because of that, there are several things to watch out for when the board is mounted into its metal enclosure. The power transformer, especially if it doesn't come completely encased in a metal shield, will be surrounded by 60-Hz magnetic fields. Keep it as far as possible—preferably 2 or 3 inches—from the oscillator circuit board. Arrange things so the various control leads leaving the board are short, direct, and away from the transformer and ac wiring.

One particular problem is hum coupled from the ac switch leads running to the back of the output potentiometer. Use relatively small wires for this purpose, tightly twisted to provide a measure of magnetic shielding. Notice in the photograph that those wires approach the potentiometer from the back while the audio connects to the front. The ac leads are also dressed perpendicularly to the circuit board instead of running alongside it.

Despite these precautions, the wires in my unit couple a small 60-Hz signal into the channel occupying one side of the circuit board. The hum is 70 dB below the oscillator tone and could probably be reduced further by electrically shielding the wires with some braid taken from a short length of RG-58. I didn't bother because the hum is no larger than some of the other spurious signals and few sideband rigs will respond to inputs at 60-Hz in any case. I had the means to measure that hum, however, and you may not, so take some extra care when positioning things in your box.

The metal case is connected to the circuit ground at only a single point: the hole where the shielded microphone cable leaves the box. This single-point grounding eliminates some potential sources of noise by separating signal currents from whatever noise currents might be flowing in the shield wall.

Test equipment is often seen as a corner that's all too easy to cut. Perhaps infrequently used, often expensive, usually bulky, it's just easier to put up with antiquated gear or do without altogether. The older equipment, while better than nothing, is often basically unsuited to an amateur's needs. You'll find this two-tone tester, even if you only use it once or twice a year, a convenient gadget well worth having. Small and inexpensive, yet reliable and easy to use, it's a good solution to several transmitter testing problems. The high-quality output also will put an end to any nagging concerns about the purity of the audio you've been getting from that old patched-up kit oscillator! ■

Yaesu, Icom Graft Revealed

Splice Icom's headset to Yaesu's talkie and discover handie happiness.

One of Icom's accessories for their VHF handie-talkies is the HS-10 headset and its accompanying HS-10SB switch box. Priced at just under $40.00, this headset with its attached boom mike is perfect for mobile use with a handie-talkie. Instead of holding the heavy transceiver up to your mouth to talk and up to your ear to hear, you simply slip the headset over your head and ham it up in comfort. The HS-10SB switch box is a necessary companion to the headset since it contains a small mike preamplifier (which boosts the audio so you don't have to talk directly into the boom mike) and a push-to-talk (PTT) switch which has both momentary-on and locked-on positions.

As soon as I saw this handy device, I decided that I had to make it work with my Yaesu FT-208R transceiver. This article describes the modifications needed to make it work.

The modifications consist of two parts: Cut off the Icom mike connector and substitute a Yaesu connector, and make a few minor changes to the HS-10SB switch box.

Fig. 1 shows the diagram of the original switch box. The mike signal is applied to a 2k volume control, and its output is then amplified by a one-transistor amplifier. The output is then sent, through the PTT switch, to the transceiver through the white wire in the coiled cord. The white wire actually serves three purposes:

(1) It carries amplified mike audio to the transceiver.

(2) It provides several volts of dc to the mike amplifier when the PTT switch is closed. This voltage provides the Vcc (collector supply voltage), base bias, and also a bias to the electret mike itself (through the 2k volume control).

(3) It also keys the transceiver when the PTT switch is closed.

Speaker output coming in on the red wire is sent to the earphone in the headset through a 33-Ohm resistor to slightly reduce the volume level. In addition, a 10-Ohm resistor provides the load for the transceiver's audio amplifier.

Finally, ground is connected through the shield in the coiled cable as well as through the blue wire.

The PTT circuit in the Icom combines mike audio, PTT, and Vcc voltage on one wire. The transceiver's battery connects to the white wire through a resistor. When the PTT switch is closed, the transceiver detects the slight voltage drop across that resistor and keys the transmitter. At the same time, this resistor also supplies the required voltage for the amplifier and electret mike.

The mike interface in the Yaesu FT-208R is completely different. It uses a six-pin mike connector which provides separate pins for audio in, PTT, and Vcc for a mike amplifier or for mike bias. An advantage of this scheme is that the Yaesu dis-

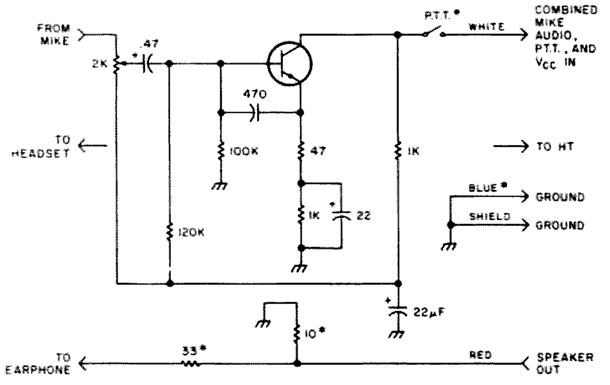

Fig. 1. The original circuit of the Icom switch box. Asterisks show components to be removed or rewired—see text

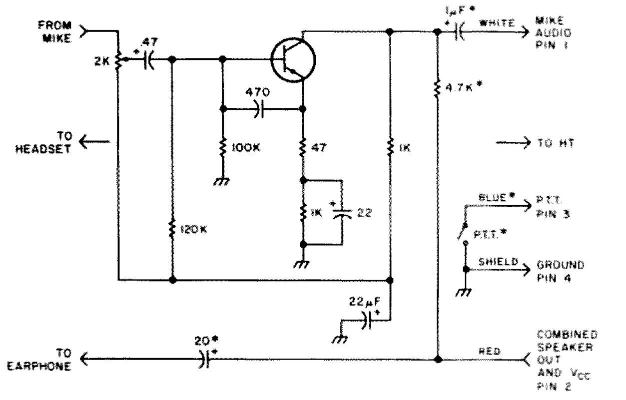

Fig. 2. Modified Icom switch box for use with Yaesu FT-208R. Asterisks show new or rewired components.

ables the built-in mike on the handie-talkie when the remote-mike PTT switch is closed. In addition, the speaker output from the Yaesu radio carries a dc voltage, which requires a slightly different earphone circuit as well.

Fig. 2 shows the modified circuit of the switch box (asterisks in Figs. 1 and 2 identify those components which have to be changed or added).

In Fig. 2, a 1-uF capacitor is used to isolate the amplifier output from the white wire. This prevents dc voltage from being fed back into the transceiver's mike circuit. Likewise, a 20-uF capacitor couples speaker audio from the transceiver to the earphone and prevents dc from getting to the earphone. Both capacitors are electrolytics or tantalums, and polarity must be as shown in the diagram.

A 4.7k, 1/4-Watt resistor is added to provide the required dc voltage for the amplifier and mike circuit. Although the Yaesu has a separate dc output on its connector, that output cannot be used because it would require one more wire in the coiled cable. Since the cable only has three leads plus a shield, I chose to get the dc voltage from the speaker output.

Finally, the PTT switch is wired directly between the PTT pin and ground.

All of the added components and wires fit neatly into the HS-10SB switch box as long as you use very small capacitors and are careful about component placement. There are several obstructions in the case, and you may have to bend the leads in several places to allow the case to close. As shown in Fig. 2, the original Icom cable is also used, although the blue wire has to be unsoldered from the ground connection and reused for its new purpose.

On the transceiver end, you will have to cut off the original Icom connector and substitute the required Yaesu connector. I obtained mine by calling Yaesu (see their ad in this issue). Although the connector is tiny and requires care in soldering, it was not particularly difficult. It has six pins, though only pins 1 through 4 are actually used in this modification. Fig. 3 shows the pin layout of that connector on the FT-208R, but note—it is possible that the orientation of the connector on your rig may be different from that on mine. Use an ohmmeter to identify pin 4, the ground pin, before you start to work.

I took one shortcut in this design that you should be aware of. In the original Icom design, power is applied to the microphone circuit only when the PTT switch is closed during transmitting, whereas my circuit applies power during receiving as well. This introduces an extra battery load of slightly over 1 milliampere. I decided that this was not important and let it go. But if you feel strongly enough about it, there is a way out. The PTT switch in the switch box is a DPDT switch, with the two sections paralleled. By disconnecting one section of the switch and placing it in series with the new 4.7k resistor, you can ensure that the mike amplifier is powered only when the PTT switch is pressed. ■

Stare-Way to Heaven

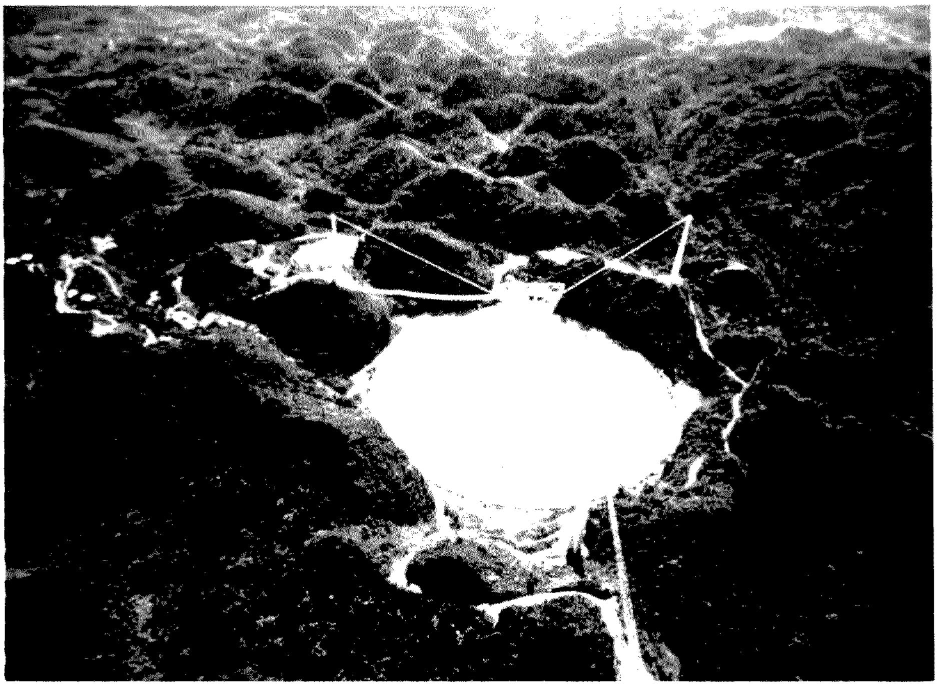
At the Arecibo observatory, the sky's the limit. Who said size doesn't matter?

The Arecibo observatory on Puerto Rico holds several records in the field of radio. Its antenna, with a diameter of 1000 feet, is the largest antenna in the world. The 450-kW output of the S-band (2.400 MHz) transmitter together with the gain of the antenna, which at this frequency is estimated to be 72 dB, make the signals from Arecibo the strongest signals to leave Earth. Although higher resolution can be achieved by other radio telescopes by coupling two or more of these together, the Arecibo observatory still has the highest sensitivity to weak signals from space.

The observatory is located about 6 miles from the port city of Arecibo, near the north coast of Puerto Rico. The landscape around the observatory is very beautiful and scenic, consisting mainly of limestone hills and valleys covered with lush tropical vegetation.

The 1000-foot reflecting antenna makes the Arecibo observatory a very conspicuous landmark when seen from the air. The reflecting dish was constructed in a natural limestone sinkhole, the shape of which was such that only small excavations were necessary to make room for the huge reflector. The surrounding limestone hills are helpful in shielding the observatory from man-made radio noise. The isolated location of the facility adds to this protection.

The reflector at the Arecibo observatory is mounted firmly in the ground, in contrast to other radio telescopes which search the sky by moving the entire antenna dish. Radio telescopes are usually constructed with a parabolic reflecting dish, but in order to be able to search the sky without moving the entire reflecting dish, a different shape had to be chosen for the Arecibo reflector. It has, therefore, been shaped like a section of a perfect sphere. With this construction, the observatory can be steered by moving secondary antennas which are receiving the signals that are being reflected from the dish. These secondary antennas are mounted on a triangular platform about 450 feet above the reflecting dish. The platform is suspended by steel cables from three towers that have been built around the edge of the reflector.



The 1000-foot reflecting dish at Arecibo was built in a natural limestone sinkhole.

Radio telescopes with parabolic reflectors have a point-like focus. The secondary antenna or feedhorn which receives the signals from parabolic reflectors has to be mounted at the focal point in front of the dish. But the focus of the Arecibo observatory, with its spherical reflector, is along a line above the reflecting dish. The secondary antennas, therefore, have to be suspended above the reflector and must be able to pick up signals along that line.

The position of the platform and the secondary antennas must remain very stable, even in strong winds. The necessary stability has been accomplished through a great deal of sophisticated engineering. The platform is triangular, and its weight is 600 tons. A circular track, 130 feet in diameter, has been mounted under the platform. The feed arm is a structure which can rotate under these tracks. The feed-arm structure itself has a pair of tracks on its underside. These tracks are curved, so that all points along these tracks are an equal distance from the reflecting dish underneath. The secondary antennas are mounted on two carriages which can move along the tracks under the feed-arm structure. These two carriages will normally be positioned in such a way that they counterbalance each other.

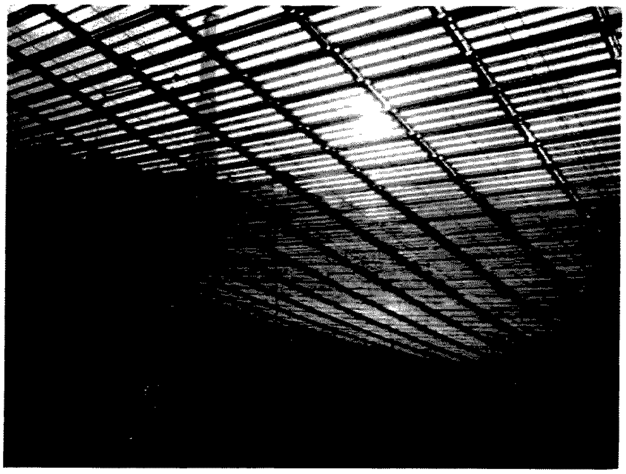
The antenna dish consists of almost 39,000 aluminum panels. These panels are perforated so that about 44 percent of the sunlight can reach the ground underneath the dish. The sunlight which passes through the dish allows vegetation to grow underneath. Without this vegetation, rainfalls would cause severe erosion of the landscape underneath the platform.

A square of laser-reflecting material has been mounted on each aluminum panel. A laser system can check the shape of the reflecting dish by bouncing light off each of these squares. A computer is then able to calculate the position of each panel to within 1/8 of an inch. The position of each panel can be accurately adjusted from underneath, and this is done whenever a sufficiently large deviation from the ideal shape of the dish has been detected.

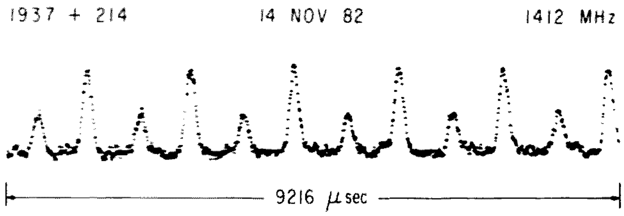
A laser system is also used to maintain the position of the platform within very narrow tolerances. A laser reflector is mounted at each of the three corners of the platform. Whenever a computer detects a significant change in the position of the platform through this system, it can regulate the tension on tie-down wires that are connected to each corner of the platform. By controlling the tension of these wires, any change in the position of the platform can be neutralized.

The radio telescope receivers are mounted inside the carriages that suspend the secondary antennas. All electronic components generate small amounts of electrical noise which is proportional to the temperature of the components. If the receivers were to work at room temperature, the internal noise would be stronger than most of the weak signals which the observatory is receiving from space. For this reason, the front end of the receivers is cooled by a refrigeration system using liquid helium. The boiling point of liquid helium is 4.2° Kelvin, and at this temperature the receivers are capable of detecting extremely weak signals from space.

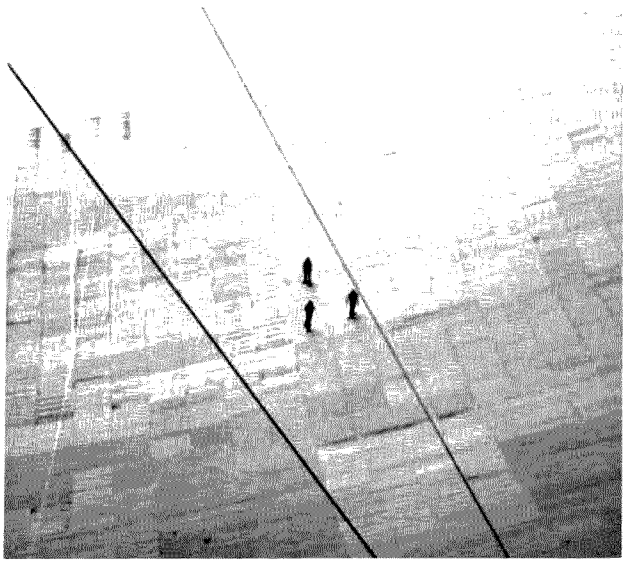
The transmitters at the Arecibo observatory are being used for ionospheric research and radar studies of the solar system. These transmitters also are mounted in the carriages in order to



The aluminum panels are perforated so that much of the sunlight can pass through. Vegetation can therefore grow under the reflecting dish, preventing erosion of the landscape.



Printout of the signal from the very fast pulsar, 4C21.53, as this was detected at the Arecibo observatory on November 14, 1982. This pulsar rotates 642 times each second and transmits one of the larger and one of the smaller pulses during each rotation.



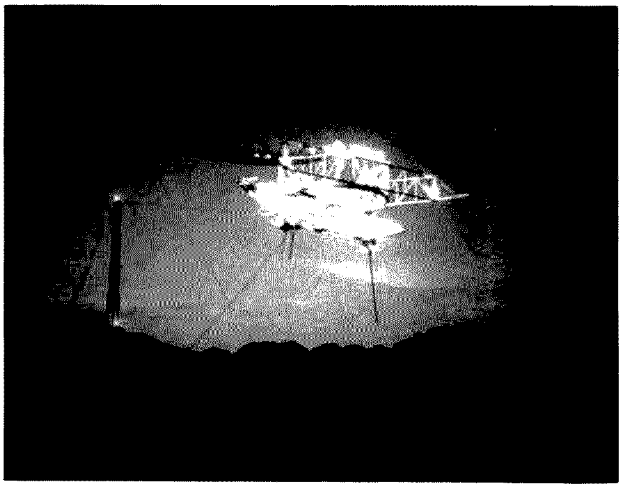
Workmen on the reflecting dish are using shoes which distribute their weight over a large area, like snowshoes. Walking on the reflecting dish is now being avoided, and almost all adjustments and repairs are being done from the underside.

The platform structure weighs 600 tons. Most of the antennas which receive the signals that are reflected from the reflecting dish are mounted on two carriages which can move along the curved track on the underside of the platform.

minimize losses in the transmission line. If coaxial transmission lines were to be used to carry the output from transmitters on the ground to the platform, the losses would be substantial at the high frequencies that are being used.

The power supply is often the heaviest part of a radio transmitter. Therefore, the power supplies for the transmitters are mounted in buildings at the edge of the reflector. Thick dc cables carry the voltages from these power supplies to the transmitters under the platform. When the radar transmitters are being used, a great deal of waste heat must be dissipated from the transmitting tubes. In order to cool these effectively, water circulates through them. Water hoses connect the transmitters with the water supply on the ground.

The observatory has been built so that a single observer can control the entire facility. The observer can steer the carriages under the platform with extreme accuracy from computers in the control room. These can therefore counter the rotation of Earth with a very high degree of exactness.



The Arecibo observatory at sunset.

All signals that are received at the Arecibo observatory are processed by computers in the control building. The frequency of the received signals can be determined to a fraction of a cycle even at microwave frequencies. Doppler shifts and emission lines in the signals from space can thus be determined. The time of arrival at the antenna for received radio signals can also be measured with an extreme accuracy.

The Arecibo observatory can at any time study a circular area of the sky about 40 degrees in diameter. This area is centered at local zenith. Due to the rotation of Earth, about 39 percent of the sky is available for observation from the Arecibo observatory. Unlike optical observatories, radio telescopes can observe the sky in daylight and during cloudy conditions. Only during strong electrical storms may a radio telescope be unable to observe.

Radar astronomy has recently contributed much to our knowledge of objects in the solar system. This technique detects the reflection of man-made signals from objects in space. The Arecibo observatory is our most sensitive radar-astronomy instrument. Through radar observations from Arecibo, the rotation period of Venus was determined for the first time. It also was determined that Venus rotates in the opposite direction of other planets. Radar maps of Venus have been produced through radar observations from Arecibo. Radar observations have also been made of the rings of Saturn, the asteroid belt, and the planet Mars.

In mankind's first deliberate attempt to announce itself to other civilizations, the enormous output power of the Arecibo radar transmitter at 2.400 MHz was used. A message was beamed to several segments of the sky in 1974. The message was coded in a binary code and contained information about mankind, Earth, and the solar system.

The first quasar was discovered by the Arecibo observatory in 1964. These remarkable objects, which are believed to be located at the center of extremely distant galaxies, emit enormous amounts of radio waves and other types of electromagnetic waves.

Pulsars are objects that emit radio waves that turn on and off rapidly. These are believed to be rapidly-rotating neutron stars that emit radio waves from the magnetic poles. Each time a rotating magnetic pole sweeps past Earth, another pulse can be detected at Arecibo. Although the first pulsar was found by an English radio telescope, many of the numerous pulsars that since have been detected were found first by the Arecibo observatory.

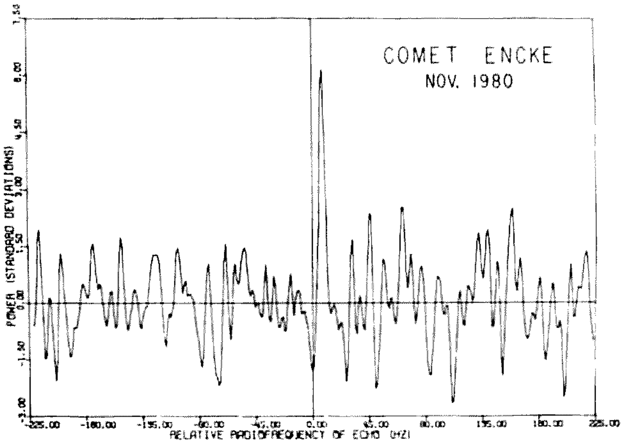
Galaxies are not distributed evenly throughout the universe but seem to be concentrated in clusters, superclusters, and huge filaments in space. In between there are huge voids with few or no galaxies. The Arecibo observatory has devoted much of its observing time to the mapping of galaxies and systems of galaxies.

The Arecibo observatory, together with other radio observatories, has been able to identify a number of molecules in the space between stars in the Milky Way. Clouds of interstellar molecules are believed to play an important role in the birth of new stars. Much of the observing time at the Arecibo observatory is therefore also being devoted to the mapping of molecular clouds in space.

The US Congress has decided recently to fund a program which will search for radio signals from other civilizations in our galaxy. This program, which is being

managed by the National Aeronautics and Space Administration, will cost two million dollars each year. A number of radio telescopes will be used in this program, including the Arecibo observatory. In the next few years, between five and ten percent of the observing time at Arecibo will be used in the search of signals from other civilizations.

During their journey out into space, the two *Voyager* space probes are making continuous observations of cosmic rays, magnetic fields, and the solar wind. As the most sensitive radio-receiving instrument on Earth, the Arecibo observatory will be able to receive signals from these space probes long after they have become too faint for other radio telescopes. If no malfunction occurs in the radio transmitters aboard these space probes, their signals should be detectable at the Arecibo observatory for at least 30 more years.



Radar echoes from the nucleus of the comet Encke were detected by the Arecibo observatory in November, 1980. This is the first detection of the nucleus of a comet. The strength of the received echo indicates that the nucleus has a diameter of about 2 miles. The rotation and speed of the nucleus can be determined from the Doppler shifts in the echo.

The Arecibo observatory, which was completed in 1963, is being operated by the National Astronomy and Ionosphere Center at Cornell University. About 100 persons are employed at the observatory in Arecibo, and another 40 persons are working at Cornell University's Astronomy Center in Ithaca, New York. Observing time at the observatory is available to astronomers from all countries.

The Arecibo observatory is being improved constantly as new equipment and technologies become available. The observatory has contributed much to our knowledge and understanding of the universe during the past 20 years. It is likely that the Arecibo telescope will remain one of mankind's most sensitive and versatile astronomical observatories for many years to come. ■

Counter-Productive Basics: Part I

Digital needn't be difficult. Let K4IPV guide you through the fundamentals of frequency counting.

Digital frequency counters have long been a favorite means of measuring the frequency of operation of radio transmitters, but until recently their cost has been prohibitive for amateurs. Until about a decade ago, only the wealthiest shops and laboratories could afford a counter. Most commercial service shops of that era used heterodyne frequency meters, not counters.

In the early seventies, however, costs started falling. The 5-kilobuck 500-MHz counter dropped in cost to about 2 kilobucks. During that same period, the first amateur-grade counters were on the market. Heathkit™ offered their IB-101. That counter sold for around $200 in kit form and operated to 15 MHz (my sample actually worked well to 23 MHz). Today, amateur-grade counters can be bought for less than $100 and operate to frequencies up near 600 MHz.

The photographs show three different models which represent the types used by amateurs. The Heath IM-2410 (Photo A) operates on frequencies up to 225 MHz. This is a basic counter with the minimum features needed. The Heath IM-2400 shown in Photo B is also a basic counter but is hand-held and portable. The IM-4110 shown in Photo C is more than a basic counter; it contains a number of interesting features. It is a frequency counter (to 110 MHz) and also will measure events and period. The period-measurement function also measures period average, which is the period measured over 10 seconds.

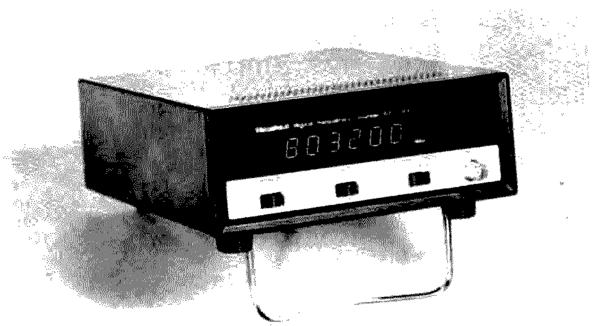

Photo A. The Heathkit IM-2410 portable frequency counter.

The advances in digital electronics over the past decade coupled with rapidly falling IC prices have made amateur use of counters possible. Even though counters are low cost now, they are not foolproof. There are problems in operation that cause erroneous readings—or no readings at all.

In this part of my two-part series, I will discuss the basic theory behind digital counters. In part II, I will discuss some of the nuances of digital frequency-counter (DFC) operation.

Digital Counter Basics

A single article cannot fully discuss enough digital electronics unless a few assumptions are made. For those who want more detailed treatment, I recommend my digital electronic series in *73* for September through November, 1982. In this article, I will reiterate only a small amount of the digital-basics series.

A flip-flop (F-F) is essentially a 1-bit memory element. There are several different types of flip-flops, but the type which concerns us here is the J-K flip-flop shown in Fig. 1(a). There are two complementary outputs on the F-F, labelled Q and $\overline{Q}$ (i.e., "not-Q"). Since these outputs are complementary, one will be HIGH when the other is LOW; these outputs will never be at the same level.

There are five inputs on the J-K F-F. These inputs are: J, K, clock, set, and clear. The J and K inputs are essentially control inputs; their use will be explained shortly. The clock input synchronizes the F-F operation and usually has a square wave applied. The set input is

used to force the F-F to the state where Q = HIGH and $\overline{Q}$ = LOW. Clear is just the opposite; it forces the outputs to the state where Q = LOW and $\overline{Q}$ = HIGH. The usual circuit symbol is that of Fig. 1(a). This example, incidentally, uses active-LOW set and clear inputs, which is the usual case in TTL devices. We do, however, sometimes see active-HIGH inputs.

Fig. 1(b) shows the truth table for the unclocked (or direct mode) operation. In this mode, the J-K F-F doesn't care what the signals at the clock or J-K inputs are doing. Only the set and clear inputs are used. Since our example uses active-LOW inputs, the state in which both set and clear are LOW is disallowed. In that case, the poor flip-flop won't know what to do. If the set is made LOW, the Q output goes HIGH and not-Q goes LOW. If set is HIGH, and clear is LOW, we see exactly the opposite situation: Q is LOW and not-Q is HIGH. If both set and clear are HIGH, then the F-F will be in the clocked mode of operation.

The truth table for clocked operation of the J-K flip-flop is shown in Fig. 1(c). The clock synchronizes the operation of the J-K F-F; all action takes place on the negative-going (i.e., HIGH-to-LOW) transition of the clock signal. In all cases of clocked operation, the set and clear inputs must remain HIGH. The programming of the F-F takes place on the J and K inputs.

If both J and K are LOW, then there will be no change on the Q and not-Q outputs regardless of clock-input transitions. In this condition, the J-K F-F is locked.

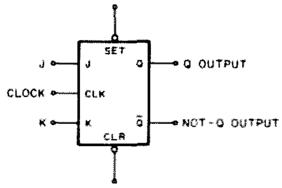

Fig. 1(a). A J-K flip-flop.

If J is LOW and K is HIGH, the Q output will be LOW and not-Q is HIGH. Action takes place on the negative transition of the clock line.

If J is HIGH and K is LOW, then the Q goes HIGH and not-Q is LOW. As in the previous case, the transition occurs on the negative transition of the clock line.

If both J and K are HIGH, then the outputs will go to the opposite state. If, for example, Q = HIGH, then on the negative transition of the clock line the Q output will go LOW. Similarly, if Q had been LOW, the clock transition would have made it go HIGH. This is the condition used in digital-counter circuits and results in binary frequency division.

Fig. 2(a) shows a two-stage binary divider based on J-K flip-flops, while Fig. 2(b) shows the timing waveforms. Note that on both flip-flops the J and K inputs are tied HIGH. The outputs are Q of F-F 1 (i.e., Q1), and Q of F-F 2 (i.e., Q2). The input signal is applied to the clock of F-F 1, while the clock of F-F 2 uses the Q1 signal as its input.

In the timing diagram, the negative-going transitions are labelled T1, T2, T3, and T4. At time T1, the input signal makes a negative transition, so Q1 snaps HIGH; Q2 remains LOW. The Q1 output remains HIGH until the next negative-going transition of the input signal, at time T2. At this time, the clock input of F-F 2 sees Q1 drop LOW, so it will cause Q2 to snap HIGH. At time T3, another input negative-going transition occurs, so Q1 goes HIGH again; it will remain HIGH until the next negative-going transition at time T4. At T4, both the clock inputs of F-F 1 and F-F 2 see negative-going transitions, so both Q1 and Q2 go LOW.

J	K	SET	CLEAR	CLOCK	Q	$\overline{Q}$

J	K	SET	CLEAR	CLOCK	Q	$\overline{Q}$
0	0	1	1		NO CHANGE	
0	1	1	1		0	1
1	0	1	1		1	0
1	1	1	1		GOES TO OPPOSITE	

NOTE: 1 = HIGH
0 = LOW
x = DOESN'T CARE

Fig. 1(c). Truth table for the clocked mode of operation.

Note what has happened in Figs. 2(a) and 2(b). There are four input pulses, yet Q1 produced only two output pulses; F-F 1 acted as a binary divider (i.e., divide-by-2). Similarly, the input of F-F 2 sees the two pulses at Q1 and produces one output pulse; F-F 2 also acted as a binary divider. Thus, the output of F-F 2 is one-fourth the input frequency. In a cascade chain of J-K F-Fs the binary division will be 1 (i.e., the input frequency), 2, 4, 8, 16, 32, and so forth.

A decade counter is a divide-by-10 (i.e., base-10) counter. Such a counter circuit is needed in decimal-counting systems used in our digital frequency counters. Unfortunately, there is no 10 in the 2, 4, 8, 16 sequence of a four-stage binary counter. We can, however, make a decade counter from a four-stage binary (i.e., base-16) counter by causing it to reset to 0000 after the tenth input pulse. Such a circuit is shown in Fig. 3(a), while its timing is shown in Fig. 3(b).

The decade counter is a base-16 binary counter modified by the addition of a NAND gate (G1). The timing diagram shows the circuit action. The output of G1 is

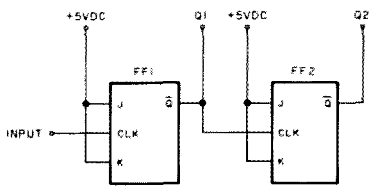

Fig. 2(a). Two-stage binary divider based on J-K flip-flops.

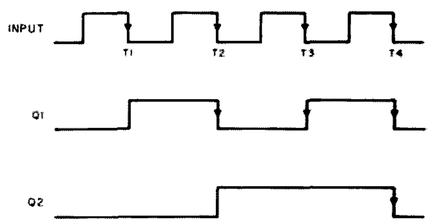

Fig. 2(b). Timing waveforms for Fig. 2(a).

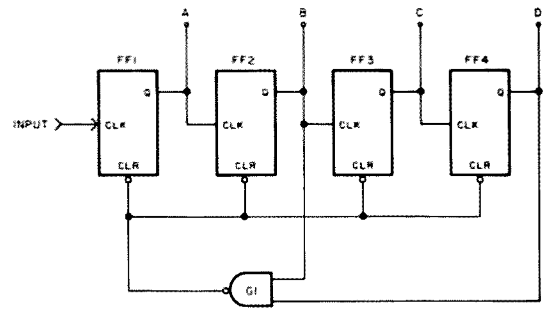

Fig. 3(a). Four-stage binary-counter circuit.

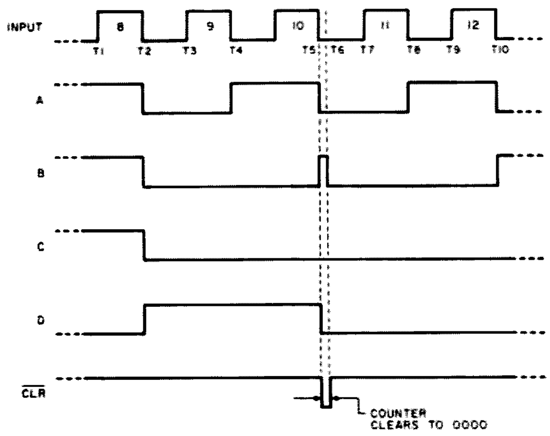

Fig. 3(b). Timing waveforms for Fig. 3(a).

connected to a common clear line. When this line drops LOW, the outputs of the counter go to 0000_2. The inputs of G1 are connected to the B (i.e., Q2) and D (i.e., Q4) flip-flop outputs. If B and D go HIGH simultaneously, then the output of G1 goes LOW and all four flip-flops will be reset. The only time these conditions are met is at T5—see Fig. 3(b). Following T5, the counter is 0000_2 and begins all over again.

The A, B, C, and D outputs form a four-bit binary-coded decimal (BCD) "word" that denotes the ten digits of the decimal numbers system. This code results in ten unique binary codes. These BCD codes are shown below:

D	C	B	A	Decimal
0	0	0	0	0
0	0	0	1	1
0	0	1	0	2
0	0	1	1	3
0	1	0	0	4
0	1	0	1	5
0	1	1	0	6
0	1	1	1	7
1	0	0	0	8
1	0	0	1	9

There are a number of IC digital counters on the market. One of the oldest is the 7490 TTL device. The 7490 is a biquinary counter, i.e., it contains one divide-by-2 counter stage and one divide-by-5 counter stage. When the output of the binary stage is connected to the input of the quinary stage (i.e., pins 1 and 12 are shorted together), the 7490 becomes the decade counter of Fig. 3(a).

Most modem frequency counters made today do not use the 7490 but rather will use MSI or LSI multi-stage counters. We will, however, use the old-fashioned 7490 device here to illustrate a principle that would be lost in the maze of an MSI device. Fig. 4 shows a decimal counting unit (DCU) based on the 7490 and certain companion chips, the 7475 quad-latch, and 7447 BCD-to-seven-segment decoder.

A DCU will count by tens and produce a decimal output. In the case of Fig. 4, the display device is the familiar seven-segment LED decimal display. This form of display uses seven lighted bars (designated a, b, c, d, e, f, and g) to represent the ten digits of the decimal system.

The 7447 receives a BCD 4-bit word at its inputs and causes the appropriate outputs (a–g) to drop LOW. When an output is LOW, the corresponding segments of the display turn on. Besides the BCD inputs, there are also a test input, a ripple blanking input (RBI), and a ripple blanking output (RBO).

The test input is sometimes called $\overline{LT}$, for "lamp test." When the test input is brought LOW, all 7447 outputs go LOW. This situation forces the seven-segment display to show an 8. This input allows us to test the display decoder device.

The RBI and RBO terminals are for ripple blanking, i.e., the suppression of leading zeros. Let's consider a

Photo B. The Heathkit IM-2400 hand-held frequency counter.

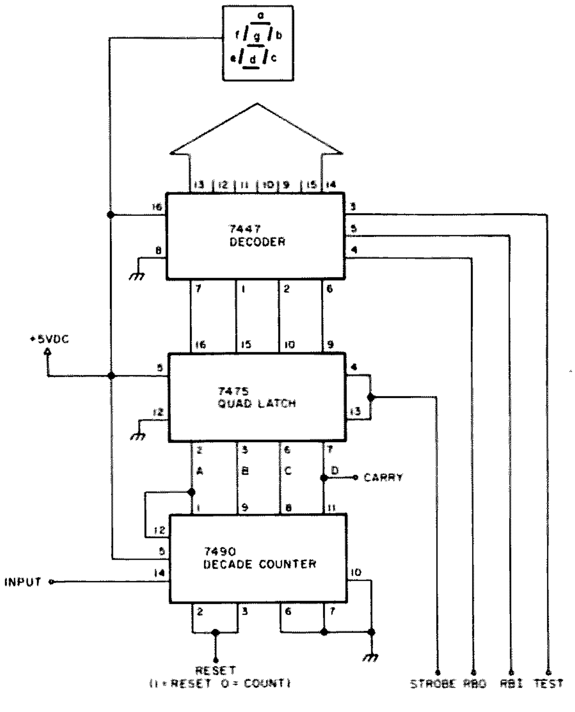

Fig. 4. A decimal counting unit.

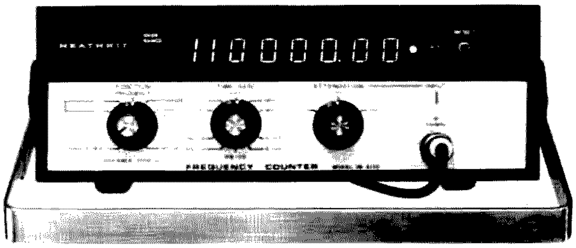

Photo C. The Heathkit IM-4110 frequency counter.

situation. Suppose our eight-decade counter measures a frequency of 21390 kHz. Without ripple blanking, the reading would be "00021390." If we provide blanking, however, we can turn off those leading zeros and display 21390. If a LOW is placed on RBI, the display will turn off if the applied BCD word is 0000_2. The RBO output goes LOW if the BCD input is 0000_2. Thus, by daisy-chaining the RBO outputs to the next least-significant RBI inputs, the leading zeros are suppressed.

The 7475 is quad-latch, i.e., a four-bit memory. Inside the 7475 are four type-D flip-flops. These F-Fs are arranged in two groups of two each. Each group of two has a common clock line. In Fig. 4, the clock lines are tied together to form a common strobe line. When this line is made HIGH, the BCD word at the 7475 inputs is transferred to the outputs. Thus, we can use the strobe line to update the display only after the decade counter has finished counting.

A decimal counting assembly (DCA) is made by cascading two or more DCUs. The D output of less significant DCUs is connected to the input terminal of the next significant DCU. We require one DCU in the DCA for each decimal digit of the DCA.

Frequency Counters

A digital frequency counter measures events per unit of time (EPUT) to form a DFC; we arrange a DCA so that input pulses are counted for a specific period of time (e.g., 1 second, or subdivision thereof).

Fig. 5(a) shows the basic block diagram for a frequency counter. The sections include the DCA, main gate, trigger, input amplifier, main-gate flip-flop, timebase, and a display clock.

The DCA is a totalizer counter as shown in Fig. 4. The overflow stage is a flip-flop that is SET when the MSD carry output goes HIGH. The overflow flip-flop turns on a lamp to make the operator aware of the overflow condition so that the data can be disregarded.

Since a frequency counter measures events per unit of time, i.e., cycles per second, the DCA must be turned on only for a given period of time (e.g., 0.1, 1, or 10 seconds). The main gate, main-gate flip-flop, and timebase sections are used to allow input pulses into the DCA for the designated period of time.

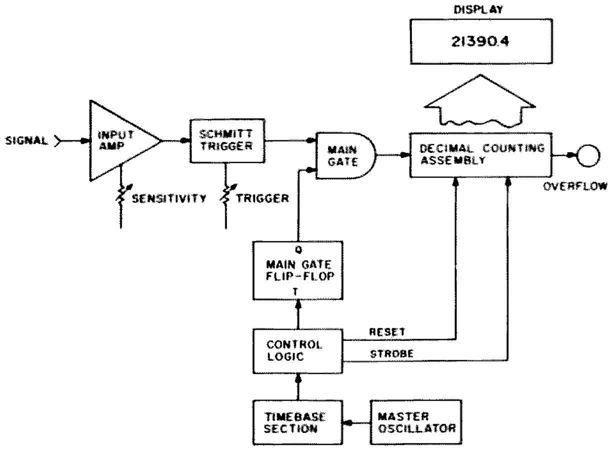

Fig. 5(a). Frequency-counter block diagram.

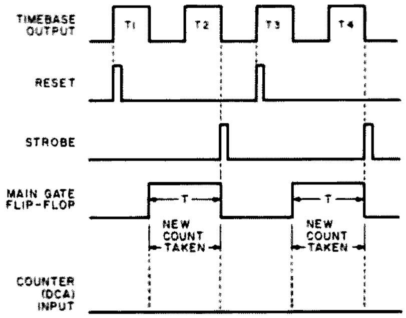

Fig. 5(b). Waveform for Fig. 5(a).

The timebase section consists of a crystal oscillator that produces pulses at a precise rate such as 100 kHz, 1 MHz, 4 MHz, etc. A chain of decade dividers such as the 7490 is used to reduce the crystal-oscillator frequency to a lower frequency. The timebase-output frequency will be 10 Hz for 0.1-second, 1 Hz for 1-second, and 0.1 Hz for 10-second measuring periods.

The timing diagram for one complete interval of an EPUT counter is shown in Fig. 5(b). Pulses t1, t2, and t3 are output from the timebase section. When t1 goes HIGH, the control-logic section generates a short pulse to reset the DCA to zero. When t1 goes LOW again, the Q output of the J-K main-gate flip-flop will go HIGH. The main (AND) gate has one input tied to the Q output of the flop-flop, and the other input is tied to the signal being counted. As a result, the main gate passes input pulses to the DCA only when the Q terminal of the flip-flop is high.

The flip-flop remains set until the negative of t2 occurs. At that time, the Q output of the flip-flop drops LOW, turning off the flow of pulses into the DCA, and causes the control-logic sec-

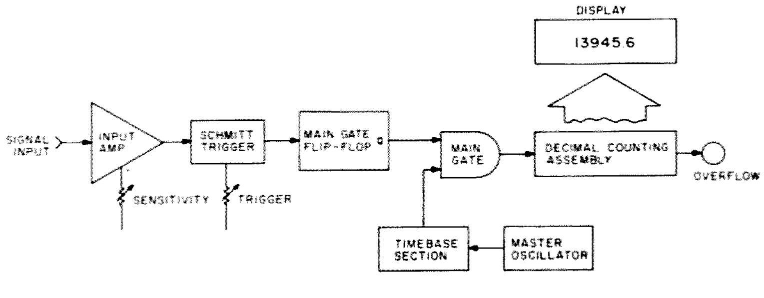

Fig. 6. Period-counter block diagram.

tion to generate a strobe pulse. This pulse tells the DCU latches to transfer data from the counter to the decoders. The display, then, shows only completed count cycles and will hold the previous count until the end of the next interval. (The trigger and input amplifier circuits will be discussed in part II of this article.)

The frequency counter of Fig. 5(a) counts frequency, i.e., events per unit of time, because the DCA is enabled only for a specific unit of time. The frequency of the input signal is the number of counts accumulated on the DCA divided by the timebase period in seconds. The basic formula, with P = time in seconds and f = frequency in Hertz, is f = counts on DCA/P. Therefore, P = DCA count/f. For example, if the DCA count is 8026 and the timebase frequency is 10 kHz, then $P = 8026/10^4 = 0.8026$ seconds.

The resolution is the smallest time interval that can be measured on the counter and is defined as the reciprocal of the timebase frequency. In this example, it would be $1/10^4 = 0.1$ ms.

Period Counters

Period is the reciprocal of the frequency being measured: $P = 1/f_{Hz}$. We can use the digital counter to measure period by reversing the roles of the timebase and input amplifier trigger. In Fig. 6 we see the block diagram of a period counter; compare with Fig. 5(a). Note that the main-gate flip-flop is turned on and off by the output of the input-signal trigger. The DCA is actually counting the number of timebase pulses between successive input pulses.

In part II, I will discuss DFC applications and some of the problems that arise in less-than-ideal practical situations. ■

Messing with Heath

This 101 control mod proves fun and easy with frequency. Your rig deserves it.

A remote vfo is useful for a lot more than just chasing DX. You can search for a clear frequency (and sometimes find one) without giving up the original, or stay with a net while moving off frequency to pick up side traffic and intercept QRM. In a contest, you might leave the main vfo on a pileup and tune the remote down the band for a few points. By switching back and forth, you can keep track of the pileup without sacrificing other contacts.

A second vfo will also serve as an RIT if your rig doesn't have one and could even be set up to monitor two frequencies at once. Of course, when you aren't doing any of these, you *can* use it to work DX stations on split frequencies.

Even though Heath didn't offer a matching remote for the HW-101, it's neither expensive nor difficult to add this versatile accessory to your HF lineup. The HW-101 will work with a variety of vfo circuits, and interfacing one to your rig is a simple procedure.

Suitable Donors

The search for a compatible unit is made easier by realizing that several Heath products were designed around the same vfo parameters. This means that an LMO (linear master oscillator) taken from a worn-out SB-101 transceiver or SB-400 transmitter, for example, will perform as well as a vfo retrieved from a junked HW-100 or HW-101.

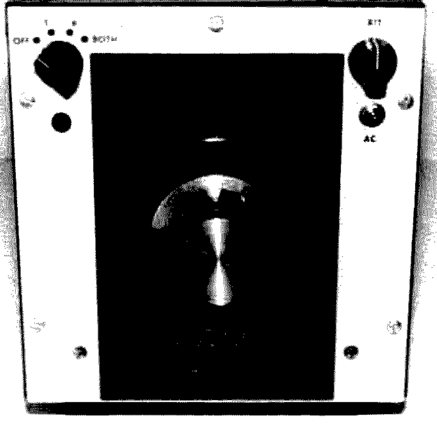

Photo A. A duplication of the HW-101's internal vfo is installed in a recycled Heath VF-1 cabinet. The original vfo in this 25-year-old box could drift through most of a band in one evening. Perfect for gradual QSY in a contest.

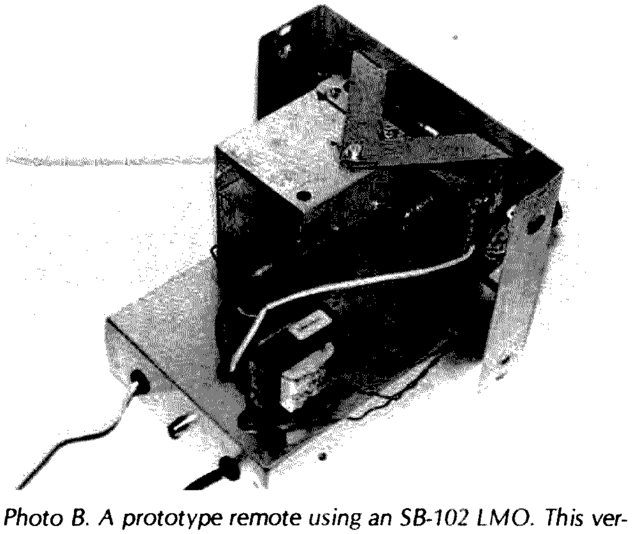

Photo B. A prototype remote using an SB-102 LMO. This version is self-powered by an on-board 10-V-dc supply.

Old, abused, and just plain broken Heathkit/HF products are often available at bargain prices. Aside from providing the vfo you want, these castoffs will give up a wealth of good reusable parts and a cabinet for your next project.

If you don't turn one up that way, consider building a clone of the HW-101's internal vfo. Obtain the enclosure, variable capacitor, and other critical components from Heath. The tube and hardware are commonly available. You might devise your own dial assembly, or buy those parts from Heath, too. Consult the owner's manual for Heath part numbers.

Duplicating the internal vfo costs more than building a generic 5-MHz circuit, but it does have the advantage of guaranteed compatibility. Also, having step-by-step instructions in the manual eliminates all the guesswork and simplifies alignment.

A Heath SB-640, although rare, is a prize find. This is a remote LMO once sold as a companion to the SB-101, but it makes an excellent remote for the HW-101. Locating one of these also saves the trouble of installing an unattached vfo into a new cabinet.

If you're willing to experiment, you might find a usable vfo in a discarded piece of non-Heath equipment. Any "backwards-tuning" 5.5-5.0-MHz unit capable of 1.5 volts rms across 50 Ohms should have potential.

Finally, some commercially-made auxiliary vfo's are compatible with the HW-101. Buy-and-try is the method here, but the Kenwood 520 and 820 products should be safe bets. For the dedicated build-it-yourselfer, some other sources are mentioned later. The installation/interface tips described in this article are generally applicable to almost any combination you decide to try.

The Basic Remote

Fig. 1 shows the setup used with a duplicate HW-101 vfo, whether salvaged or built from scratch. This arrangement also covers home-built or other tube-type vfo's requiring 150 volts. A small 12-volt-dc supply is built into the transceiver to power the new relay, K1, and an RIT relay (if used) in the new vfo. This dc source is usable with other modifications, too. Spare contacts on the antenna relay provide 12 V dc at separate points in both receive and transmit modes. Through switch S1, this control voltage determines when relay K1 is activated, placing the outboard vfo into operation.

The relay can be mounted in any convenient location; I attached it with an L-bracket to the rf cage. The rectangular cutout in the rear panel is an almost perfect fit for a nine-pin molex®-type female connector (Radio Shack #274-239). Either a new phono socket or the spare on the rear apron becomes the "vfo in" connector.

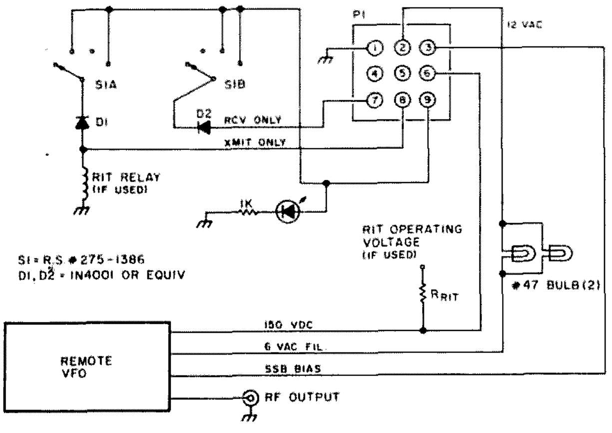
As indicated in Fig. 1, some minor rewiring of the regulated 150-V-dc line and vfo input is needed. This is done to route them through the new relay instead of direct to the internal vfo. These changes are straightforward and easily reversible.

Fig. 1 also shows the control switch and "on-site" wiring of the remote unit. With S1 in its first position, the main vfo is always used. In the next position, control is split, with the main unit receiving and the remote transmitting. The third position is just the opposite, and the fourth position puts the remote unit in complete transceiving control. Diodes D1 and D2 are "one-way signs." They prevent the control voltage from running backwards down the wrong line when the switch is set for remote transceive. For example, the RIT relay would be useless without D1.

The Better Remote

Aside from the benefits of dual-frequency control, an LMO offers dial accuracy approaching the level of digital readout. The circular dial reads 0–100 kHz rather than 0-500 and rotates five times per band segment instead of once. The 1-kHz markings can be visually interpolated to 200 Hz.

Another advantage is that warm-up drift is almost eliminated. The LMOs stabilize much faster than the original vfo and the solid-state version operates at room temperature in its own cabinet. This limits warm-up drift to the hfo circuit in the transceiver, which is minimal. With all this in mind, you may find yourself using the remote LMO most of the time. It's worth a little effort to find one.



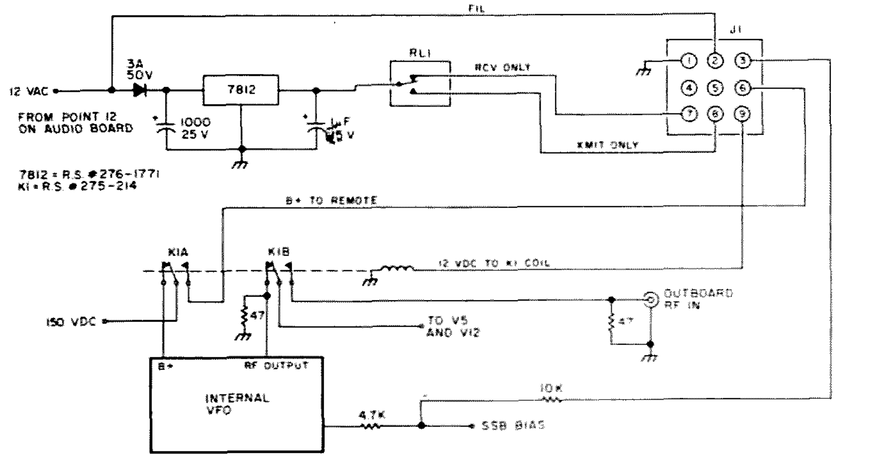


Fig. 1. Relay and 9-pin socket connections inside the HW-101. The 12-volt supply can be built on a terminal strip. Also shown is the remote-unit wiring. P1 is at the end of a 7-wire cable and mates with J1 on the transceiver rear panel.

Depending on how old it is, an LMO-equipped Heathkit will contain either a tube-type or solid-state unit. The older ones (and the SB-640 remote) require 150 V dc and should be set up the same way as the vfo in Fig. 1.

The later LMOs do without the tube and operate on +10 V dc regulated. Fig. 2 shows the changes in the interfacing arrangement and a power supply for the LMO. You could get by with a ten-volt zener on the relay supply, but the circuit shown is sturdier, safer, and more reliable. Be sure to adjust the regulator for ten volts output before connecting it to the LMO. The Fig. 2 method is readily adaptable to other solid-state remote units requiring 9 to 13 volts.

You may want RIT in the remote, especially if you plan to use it very often for transceiver control. Any circuit that works in the HW-101's internal vfo should be usable. The RIT is connected to the stator (stationary) plates of the main tuning capacitor, which in the Heath LMO is impossible to reach. Look for a tinned bar with several components soldered to it, just below the air variable, and make the connection there.

Once RIT is installed, the LMO will need realignment.

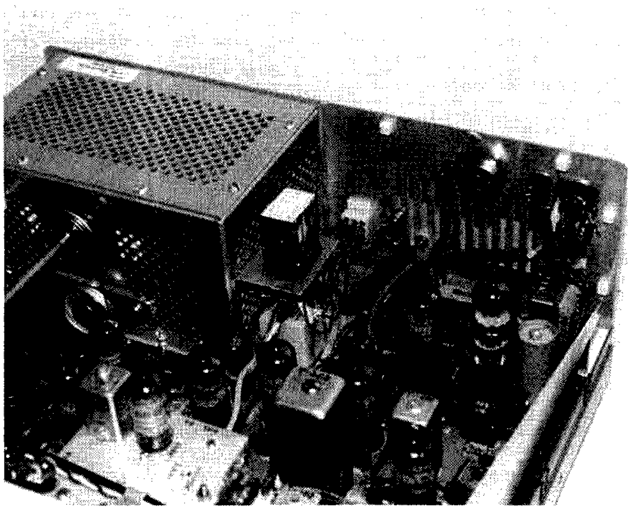

Photo C. Close-up of the HW-101 showing suggested locations for relay K1, the 9-pin socket, and remote-input phono socket.

Even without this modification, some of the more battered LMOs I've used required touching up. These units came from the factory pre-assembled, aligned, and sealed. No information was given on the circuit or its adjustment, so I tried and erred until the secret was revealed.

Calibration is done from the front of the enclosure with insulated tools. At 0.0 (shaft fully counterclockwise, then up 10 kHz), set the coil for 5.5 MHz. Go clockwise five turns and set the trimmer for 5.0 MHz. Repeat this procedure until one turn of the shaft changes the frequency exactly 100 kHz. Take some time doing this, and you'll end up with an exceptionally accurate and linear readout.

The Over-Achiever's Remote

Occasionally the need may arise to monitor two frequencies at once. This usually means trying to impress a visitor with your station's versatility, but there are more legitimate uses. If you've always envied the guys who call CQ DX and casually add, "Listening on this frequency *and* 7090 kHz," then this extra step is for you.

Fig. 3 shows one method of activating two vfos at the same time. The second new relay (K2) is drawn in squares to distinguish it from control relay K1. Whichever vfo is not being used will be turned on and connected to the mixer inputs by closing K2. This results in both units controlling a received frequency independently but simultaneously.

This system is foolproofed against transmitting on two frequencies by powering K2 from the receive-only 12-V-dc source. The relay automatically opens when the rig is in transmit mode. Nevertheless, a prominent warning light should be included as a reminder that the transmitted signal may not be in the same place as the one you're listening to.

The circuit in Fig. 3 is limited to remote vfo's that do not take their B+ voltage from the 150-V-dc line in the HW-101. The OA2 regulator tube can't handle two vfo's at the same time. If this feature is important to you, either a solid-state remote unit or a separate 150-volt supply will be needed.

Mount the second relay next to K1 and keep rf leads short and direct. Some solder-and-try with the .005 discs may be necessary if unwanted oscillation occurs.

Some Other Approaches

You may find, or already own, another Heath rig with the right vfo/LMO. If it's not ready to retire for parts, it

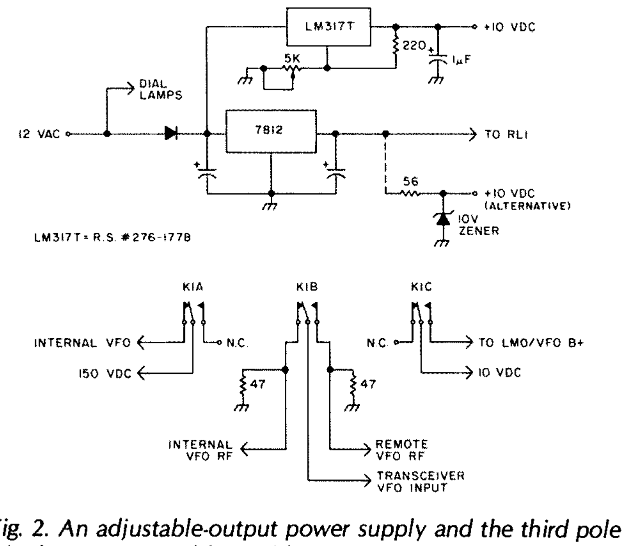

Fig. 2. An adjustable-output power supply and the third pole of relay K1 are used for solid-state remote units.

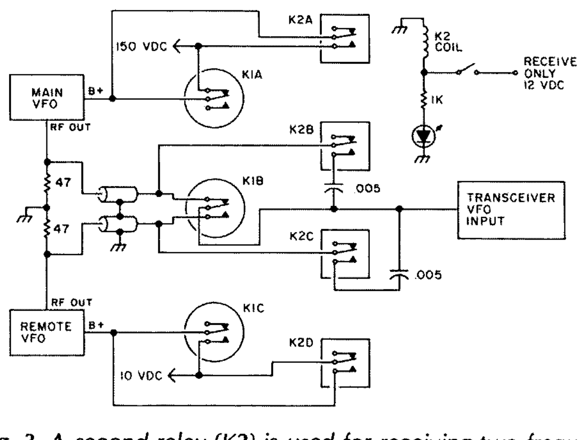

Fig. 3. A second relay (K2) is used for receiving two frequencies at the same time.

can be set up easily to function either normally or as a remote vfo.

For example, an SB-303 receiver's LMO can be used exactly as shown in Fig. 2. Mount the control switch in a separate box or in place of an expendable receiver control such as the rf attenuator. LMO output is available on the rear panel. If operating voltage is brought to the LMO through spare phono sockets, the receiver itself need not even be turned on. In the same way, an SB-110 six-meter transceiver could "loan out" its LMO when not otherwise occupied.

If by choice or necessity you build an outboard vfo, you would probably save some time by referring to previous articles on Heath companions. In "An External Vfo for the Heathkit SB-101" (CQ, September, 1972), K4TP described a tube-type unit. His circuit uses commonly-available parts and a simple dial mechanism.

VK5JZ/SK built a two-transistor version which is described on page 23 of the ARRL's *Weekend Projects for the Radio Amateur*. Look through back issues of *73* for other articles that may include a 5-MHz circuit. One in particular which has potential is VE5PZ's "An 820S Remote Vfo," in *73* for June, 1981.

These circuits should be "laundered" through a buffer. The triode section of tube V5 is not used in the HW-101 but functions as a buffer in the SB-series transceivers. By adding a few parts, V5B can be put back to work. See Fig. 4. The new components will fit into vacant holes surrounding V5 since the same circuit board was used in both transceiver types.

Refer to Fig. 1 and treat the buffer as though it were the remote unit. The actual outboard can be left on continuously or switched along with the buffer. But remember the limitations on the built-in 150-volt regulator; it won't run two of anything at once.

The V5B buffer should also benefit some other vfo's you might build or buy that don't perform properly with the HW-101. Low power output is one symptom, oscillation in the mixer is another. The buffer is more forgiving of impedance mismatch and too-high vfo output than the mixer stage.

Another step that's likely to improve compatibility is also shown in Fig. 4. The SB-100 series had more sophisticated mixer input circuits which can be added to the HW-101. Again, vacant holes are available on the bandpass board.

The SSB bias line shown with the Heath remotes is used to offset the vfo frequency when changing from LSB to USB or CW. Recalibration of the dial is then unnecessary. This feature could be included in home-built or other circuits, but probably is not worth the trouble.

Summing Up

Length of connecting coax cable and terminating resistance is considered critical with many vfo designs. In fact, Heath specifies 24 inches of RG-62 (93-Ohm coax) for interconnecting their LMOs.

At different times I've used an HW-101 vfo, several LMOs, and a few workbench contrivances. In no case was anything more than a convenient length of RG-58 needed for good performance. But don't overlook the 47–68-Ohm resistor at the mixer input and careful vfo alignment.

There's no disputing that the HW-101 is an economy radio, but you're in the company of many loyal and satisfied owners. A remote vfo will open the door to more enjoyable HF operating with a small investment of money and time. It's a very effective way to make the most of hamming on a budget.

Let me know if you encounter any problems, and I'll help if I can. ■

VK9Y—COCOS KEELING

First discovered in 1609 by William Keeling of the East India Company, these islands are located 2768 km northwest of Perth, West Australia.

The Cocos Keeling group consists of two main atolls plus several smaller islands. The main islands are West Island, Home Island, and Direction Island, with the other larger ones being Prison, Horsburgh, and North Keeling. On these islands, the highest point above sea level is only six meters, which poses some problems annually during cyclone season.

Except for the odd sailing ship stopping there briefly over the centuries, the islands remained uninhabited until 1825 when Alexander Hare settled there, followed two years later by the first of the Clunies family.

In 1886, Queen Victoria granted all of the islands' lands above high water mark to the Clunies-Ross family, thereby starting a family tradition where the head of the family was called "King of the Cocos."

When Clunies first settled on these islands, he bought with him several Malays as workers on the islands' only commodity, copra. There are now 370 direct descendants of these original Malays, a very family-conscious and happy people who call themselves "Cocos Malays." They speak both Malayan and English and follow the Muslim religion.

The rest of the islands' population consists mainly of Australians on a two-year tour of duty with one of our government departments.

Radio was first introduced to these islands in 1914, when there was a cable and wireless station located on Direction Island. In the 1940s, an airstrip was built on West Island which has since been upgraded to take large jet aircraft, one of which is the fortnightly commercial flight from Australia.

In 1978, the Australian government bought most of the islands from the Clunies-Ross family for $6.25 million, and at present, it is trying to buy what is left of the family estate.

This year, the Cocos Malays are to be given, under United Nations supervision, a free choice as to whether they wish to have independence, free association with, or integration with Australia. As there is much travelling by the islanders between Cocos Keeling and Australia and they come under the West Australian Health, Dental, and Schooling System, the feeling is that soon we will have another 370 Aussies and permanent jurisdiction over the Cocos Keeling Islands.

Amateur radio is a late comer to these islands, with VK9AJ, as far as records show, being in 1956 the first to activate amateur radio from Direction Island. Since then, there have been many operations by outsiders since none of the local Malay population has taken up amateur radio, although several do operate CB equipment. The operation of amateur radio has become extremely difficult of late, however, due mainly to there being no tourist facilities on the island, and the only way to stay for a short period is to be invited to live at someone's house. This poses some problems as all the Cocos Malays' homes are closely grouped together, with a large number of TVs, broadcast receivers, cassette recorders, and VCRs (the amateur's nightmare).

I quote part of a letter to me from Neil VK6NE/VK9YE: "To operate and not create TVI/BCI, or bad neighbor relationships, is very difficult in the living area. To use over 25 Watts will get you into some appliances. 100 Watts is OK if you tee it up with the neighbors beforehand, for a few hours operation only. 400 Watts and you will be put away. No way will the island's Administrator allow you to stay if you don't stop making the appliances emit strange sounds, and the Administrator's word is law on these islands."

Two of the most active operators of late were Paul VK9YB and Alex VK9YA, due to jobs with one of our government services which took them through there on a fairly regular basis. They have been reassigned now and are inactive from this spot, but even they could get into trouble.

One example of the problems in operating amateur radio from here happened to Alex VK9YA. Deciding to get on the air from the single-men's quarters during one of his many stopovers, he fired up his rig late at night, only to find an irate neighbor at his door. It seems that as the island's own 50-Watt broadcast transmitter goes off air during the night and starts up first thing in the morning, this chap was leaving his clock radio switched on, with the volume turned up full as a wake-up alarm. You can imagine what happened when Alex fired up his HF gear from two rooms away; the neighbor, not being interested in amateur radio, was turning very nasty and made Alex shut down his operation.

Cress VK9YC, whose home callsign is G5NDS, did not have these problems, as he is a son-in-law of the Clunies-Ross family and operated from its castle-like home on Home Island. However, with the negotiations by the Australian government trying to buy this property, you may not hear Cress from there again.

Mike Beall VK9ZYX, a limited license holder, in his shack on Cocos Keeling. Limited to 52 MHz and above, Mike still gained many awards on the 6m band.

Frank VK9NYG at his operating desk on Cocos Keeling.

A DX expedition, even if allowed to operate (which I doubt), would not be warranted, going by the figures given to me by Paul VK9YB. Out of 2500 contacts during his last stay, only 125 sent cards direct, some with no return postage included and some with only one IRC. It is worth mentioning here that we have one of the highest postage costs in the world, with air mail to the States now 75 cents and Europe 85 cents. Of the rest of his contacts, he is now getting 400 cards per month by the bureau, with a large number of SWL cards.

Perhaps the above is due to Frank VK9NYG, a Novice operator who, although limited in power and bands of operation, had, during his two-year tour of duty on the islands, 22,000 contacts (some duplicates, of course). Of these, Neil VK6NE, Frank's QSL manager, says that 6,500 cards were sent back direct, regardless of whether or not sufficient return postage was included, and 7,800 cards were sent by the bureau. Not a bad tally for a Novice operator, mainly operating on 28 MHz with 30-Watt PEP output. 21 MHz was there as a backup but seldom used.

Frank enjoyed a unique relationship with the islanders, as the radio telephone on the islands shut down at night and sometimes was not at all reliable during the day. The islanders found that they could use Frank to get info for them from the mainland, and he was able to be of assistance to yachts in trouble in the area of the Cocos Keelings. This gained him some acceptance for amateur-radio operation not granted to other amateurs. Frank and his wife Ann are back in Australia, and Frank has upgraded to a full call, now being VK6ACC.

Incidentally, Neil VK6NE is also the WIA's Federal QSL Manager, and he spent two weeks as VK9YE, operating from Frank's shack, before Frank left the islands.

With the Australian government just finishing building a six-million-dollar high-security quarantine station out there, casual visits by amateurs or anybody else will be even harder in future, and unless we get an active amateur posted to one of the government departments on the islands, I feel VK9Y will slowly start to creep up the most-wanted list again.

As Melbourne is a long way from Cocos Keeling, I must thank Neil VK6NE/VK9YE, Paul VK5CGR/VK9YB, and Ken VK3AH, who together gave me most of the information for this article.

P.S. I have just received word that the Cocos Malays just voted on their future and the vote was overwhelming in favor of integration with Australia. To use a typical Australian expression, "Bewdy mate, she's a bottler decision!"

RECIPROCAL AGREEMENT

One day before my last trip to the United States, which was on April 7, I received a telephone call from Ricardo A. A. da Silva PT2RS, one of the members of the Brazilian Amateur Radio League (LABRE) staff. He lives in Brasilia, the capital city, but he was in Rio de Janeiro for a few days due to his job.

First of all, he passed on the message from Valmir Jacinto Pereira PT2FA, president of LABRE, congratulating 73 for the opportunity it gave us, through our column, to make known a few things about Brazilian amateur-radio activities.

The president also wishes to extend an invitation to all foreign authorities of the countries with which Brazil does not have yet a reciprocal agreement to get in touch with the Brazilian League in order to work on this agreement. Up to now, Brazil has reciprocal agreements with West Germany, Bolivia, Canada, Chile, Colombia, Costa Rica, Denmark, the US, Great Britain, Northern Ireland, Panama, Paraguay, Portugal, Dominican Republic, Sweden, Switzerland, Uruguay, and Venezuela.

According to Brazilian law, it is not allowed for a foreign citizen, while in Brazil, to have or use any communication equipment if the country of which he is a citizen does not have a reciprocal agreement with Brazil. Transgressing this law will result in the confiscation of the equipment, the detention of the violator for one to three years, or his banishment from the country. All inquiries and general correspondence to the League should be addressed to the administrative headquarters at SCE Sul, Trecho 4, Lote 1-A, 70000 Brasilia, DF, Brazil, or to PO Box 07.0004, 70000 Brasilia, DF, Brazil. Telephone: (061) 223-1157 or (061) 226-0504.

EUGENIO'S FIRST CRY

This happened in the city of Fortaleza and was reported by America PY7VBG: When little baby Eugenio was born on December 8, 1982, nobody could imagine that his first cry would be transmitted on the air on a frequency full of friends of his mother, Maria PT7LB. When Maria arrived at the hospital to have her baby, at about 4:00 am, the only room available did not have a telephone, so she decided to keep with her the 2-meter hand-held equipment to get in touch with her husband; he had had to return to their home to stay with the other children, who had remained sleeping.

According to her doctors, Braga PT7WFB and Lazaro PT7HP, the baby would be born at about noon. However, at about eight o'clock in the morning, while speaking with her friends on the frequency, she felt the first hurt, and a few minutes later the first cry of Eugenio was transmitted on the air and heard by all friends who were on the frequency.

Without a license, Eugenio had to finish his first transmission a few seconds after the beginning, and then he went to his birthplace for sleeping.

CWP AWARD

Issued by CW Petropolis, the CWP award may be obtained in three different classes. Contacts eligible: only two-way CW mode, after December 1, 1983.

Class I—Work 10 Brazilian cities plus 2 contacts with CWP members or delegates.

Class II—Work 20 Brazilian cities plus 4 contacts with CWP members or delegates.

Class III—Work 30 Brazilian cities plus 6 contacts with CWP members or delegates.

One CWP member or delegate may be logged more than once, but only if worked on different dates or bands.

SWL: Same rules.

No QSL, only GCR. Fee: 7 IRCs. Mailing address: CWP, PO Box 90415, 25600 Petropolis, RJ, Brazil.

CWP members: KA9KUH, PP2ADY, PP7JCO, PT2ACZ, PT2GK, PT7WA; PY1s: AFA, APS, AYE, AZG, BPR, BVY, CC, DFF, DK, DMX, DRW, DWM, DYO, EBK, EBN, ECL, EWN, JF, KT, MIT, OB, PL, QN, QQ, RD, TBW, TG, UBS, URO, UTZ, UUW, UWI, VEC, VMV, WXU, YOC, YOV, ZFF; PY2s: AC, IL, KQ, MC, MT, ORW, RLQ, RRG; PY3CJI, PY3MQ, PY6AMJ.

IARU REGION 1 CONFERENCE, 1984

The IARU Region 1 Conference, 1984, took place from April 7th to 13th, in Cefalu, Sicily. Back in 1981, the last Region 1 Conference, in Brighton, UK, had voted for Italy by a plurality.

During such meetings, which are held every three years, the member national societies agree democratically to important decisions and suggestions for the future. That means that single-nation interests have to be combined on a level which is acceptable for every member. In the voting, each nation has one vote whether it has 50,000 members (as for example, the DARC—Deutscher Amateur Radio Club) or only 40.

Very often the negotiations are extremely difficult and many result in a compromise. So not seldom discussions last until the late night. The official language of the conferences is English, and procedures are parliamentary procedures according to Roberts Rules.

Three committees were set up in 1981 to report this year. Committee A is dealing with shortwave and administration subjects, Committee B with subjects concerning VHF/UHF, and Committee C with financial subjects.

As already mentioned, some small teams had to be founded (besides the three committees) to handle negotiations successfully. That means that a national society wanting to bring its interests into several subjects has had to have number of delegates to spread around.

A great deal of preparational work is done by these teams—HF WG (High Frequency Working Group), VHF/UHF WG, and other teams—in the time between conferences. But their suggestions are not binding because not every nation's interests have been represented. For suggestions to come into force, the whole conference has to agree.

The executive committee has suggested changing this procedure to introduce written voting so that decisions also could be made during the three-year period between conferences. DARC supports this proposal.

In a future column I will report on results, but you may be interested in other matters under discussion.

Because of the increasing numbers of QSL cards, we think it advisable to propose a standardization regarding card size and address field. (Naturally it will take several years until the standards have become common use.) Similar efforts towards standardization have been made within the two other regions. According to our experiences, we think a possible compromise would be: size 9 × 14 cm, weight 190-250 grams/sqm, address in the 12-mm leftover space at the end of the QSL (for an automatic handling of the cards).

In addition, we want considered additional regional subsidies to our local AMSAT organizations. We also suggest stopping unnecessary use of special prefixes for each and every thing. Further, we appeal for reflection upon the existing RST system for an easier way of evaluation. QRK expressed "R 1-5" seems to be sufficient.

It is already known that RSGB (UK) wants a change of the bandplan within the 28-MHz band. RSGB intends the integration of an FM-repeater range. SSA (Sweden) proposes producing and publishing a communication manual to improve radio discipline. Also they suggest a coordination of the intruder monitoring service within Region 1.

According to resolutions of Region 2 (America) and Region 3 (Asia) conferences, a uniform QTH-locator system seems to be possible now. Also, there are suggestions to reduce the 24-hour contests to 12 hours and eventually to hold two contests on the same weekend.

THE UK SCENE

Band occupancy is a problem to which I have referred in previous columns in connection with the need to continue to use the 10-meter band during periods when propagation is poor. Most people seem to accept the possibility of such bands being lost to broadcasting or to CB if used only once every 11 years or so.

However, the need to demonstrate that amateur allocations are not a waste of valuable spectrum is not confined to HF. Indeed, the pressures from the likes of land mobile PMR (private mobile radio) and military users in the VHF and UHF bands are probably much greater than those experienced in the lower frequencies. At least this seems to be the case in the UK.

The need to occupy the 1.2-GHz band to ensure that it remains in the amateur service was a major motivating factor in recent applications for amateur-television repeaters in this band. Licenses were duly granted by the Department of Trade and Industry (the government department responsible for the Amateur Service) in early 1984.

These are the first such licenses to be issued in the UK and it is hoped that they will have a significant impact on amateur-television activities. By the time you read this, the initial five repeaters are expected to be operational. The callsign, location, and channel number of each is as follows: GB3GV (Leicester) and GB3UT (Bath): RMT1; GB3TV (Luton), GB3UD (Stoke-on-Trent), and GB3VR (Worthing): RMT2.

The frequency allocations (in Megahertz) for the two channels in use are as shown here:

	Vision in	Vision out
RMT1	1276.5	1311.5
RMT2	1249.0	1318.5
	Sound in	**Sound out**
RMT1	1282.5	1317.5
RMT2	1255.0	1324.5

The repeaters operating on channel RMT1 will receive both AM and FM signals but will reradiate in AM. Repeaters operating on RMT2 will receive and transmit in FM only (the sound frequencies shown are for AM; FM systems will utilize a 6-MHz sound subcarrier).

Vision signals are to be 625-line, negative-going with positive-going synchs. All FM signals are limited to a deviation of 6.5 MHz with CCIR pre-emphasis (and therefore similar to UK PAL broadcast standards). With horizontally-polarized antennas, repeaters will be activated by the presence of a valid video signal at the receiver input.

The British Amateur Television Club operates a recorded-announcement service giving details of all aspects of the club's television activities. From the US, this can be called on 44 (533) 600108. Please note that I am not a TV enthusiast and therefore cannot oblige with any more information if anyone is thinking of writing to me on the subject!

BARTG

1984 is the Silver Jubilee of the British Amateur Radio Teleprinter Group (BARTG) whose quarterly newsletter provides a wealth of information for RTTY enthusiasts (and those interested in FAX, AMTOR, and data transmission). Details of BARTG membership, publications (including *RTTY The Easy Way*), and products (including PCBs, etc.) can be obtained from John Breedle G6MOK, 161 Tudor Road, Hayes, Middlesex UB3 2QG, England. Please enclose an IRC or two for return postage.

BREAKTHROUGH

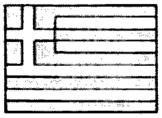
Following my previous comments on breakthrough in the 2-meter amateur band from the newly-legalized cable TV in the UK, it seems that problems may also occur with plans for Direct Broadcasting by Satellite (DBS). The BBC has been given government permission to begin transmitting DBS signals in 1985/86, and manufacturers already are looking at domestic receiving equipment requirements.

The European DBS bands will be around 11.7 GHz and designed for reception with a 1-meter-diameter dish. Such high frequencies require two i-fs, the first at the dish itself and the second on the set top. The equipment manufacturer's committee, BREMA (British Radio and Electrical Manufacturers Association), has selected initial intermediate frequencies around 1.2 GHz and 144 MHz. One can just imagine the problems for the average punter trying to receive very low level DBS signals in the presence of high-power amateur stations operating (quite legally) at the receiving system's i-fs.

These problems have been put to BREMA not only by the RSGB but also by the IBA (Independent Broadcasting Authority—the UK commercial TV operators) and the DTI (Department of Trade and Industry). Some sense has prevailed at 1.2 GHz at least, with a promise of a rethink. However, BREMA does not accept, per se,

a problem at 144 MHz and insists on more information before making any changes to its proposals. A working party has therefore been set up (typically British approach) to measure the levels of screening that can be achieved in practice and, presumably, therefore decide if breakthrough might occur.

Amateur signals are likely to be the only source of strong rf signals in the domestic environment, and it seems to me, and I suspect to the RSGB, that BREMA's attitude is somewhat negative. Rather than seeking to screen against signals that will be a problem, why not simply choose an intermediate frequency in another part of the spectrum where strong rf is not likely around the home? As if amateur stations do not have enough problems.



GREECE

Manos Darkadakis SV1IW
Box 23051
Athens 11210
Greece

Starting with this column, I would like to present to you some of the SV hams of whom you may have heard or even talked to on the bands. As I have already mentioned, DXing was something unknown a few years ago with the exception of one or two people, but over the last four years more and more new amateurs have joined a small team seriously involved with the HF bands. Nowadays there are more than 15 SV amateurs who are active almost daily.

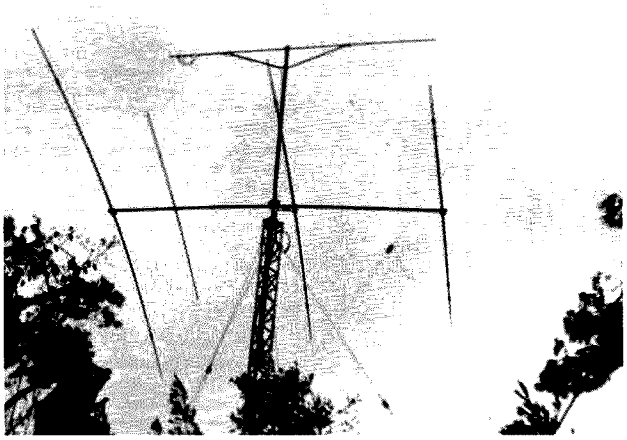
So, I'm starting the presentation with Cliff SV1JG, who is likely to be one DXer well-known worldwide and probably the most active SV amateur during the last and the present year. You may also have heard him transmitting from Mt. Athos back in 1979 and 1980 and from SV5 and SV9 quite a few times during the last 5 years.

Cliff, who is now 32 years old, is living in Ekali, some 15 miles north of Athens, in a place which was chosen very carefully with antenna installation in mind! He has already 5-band DXCC, WAZ, WAC, and a very good score in phone and CW DXCC. He prefers to work SSB and CW, and in a few days he will try the challenge of a new mode (RTTY) with his Commodore 64 computer.

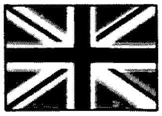
Of course, things were not so easy when Cliff started out. In 1978 he was using a TS-520 and dipoles on all bands and he managed to work more than 200 countries in less than a year and a half. Cliff also takes part in a lot of contests like the *CQ* Worldwide Contest, the WPX, the Scandinavian, the All Asian Contest, and many others. When 160 meters became available to Greek amateurs, he was one of the first to work there with a full-size inverted vee, with very good results. As he is able to transmit 300 PEP input (B class license), he gave a lot of people a new one on the top band.

Today, the station in SV1JG's QTH consists of a Yaesu FT-102 HF receiver, a Den-Tron MLA-2500 B amp, and a Heathkit® tuner. The antenna is a 4-element Cushcraft for 10-15-20 meters; dipoles and verticals are used on the low bands. For VHF and UHF, Cliff is using a Yaesu FT-480R and FT-780R, and the antennas are a 14-element KLM VHF and a 19-element F9FT UHF.

Cliff was at the Dayton Hamfest in 1981, and I hope that I will be able to join him for a planned trip in the near future.



SV1JG's antennas.



HONG KONG

P. J. Weaver VS6CT
10A Bonaventure House
91 Leighton Road
Hong Kong

Since the advent of the class B (no-code) license in Hong Kong, we now have over 100 enthusiastic VHF operators. A few are operating on six meters and one, VS6XLA, is now on satellite. The HF licensees don't seem to change too much; as fast as new arrivals get on the air, old ones leave. By the very nature of Hong Kong, we do get quite a few expatriates who come for two or more years only. HF licensees also number about 100, although there are very few active.

One of the major problems is finding suitable accommodation in Hong Kong, where high-rise apartment blocks proliferate, each building normally topped by a crown of thorns of TV antennas, each with its own broadbanded amplifier!

Socially, the locals and expatriates meet each Tuesday evening at the Cable & Wireless Sports Club, Caroline Hills Road, in the district of Causeway Bay on Hong Kong Island. This is very close to my home, and any visiting amateurs are welcome to visit me first (telephone 5-772313, between 5:30 and 6:30) before going on to the club.

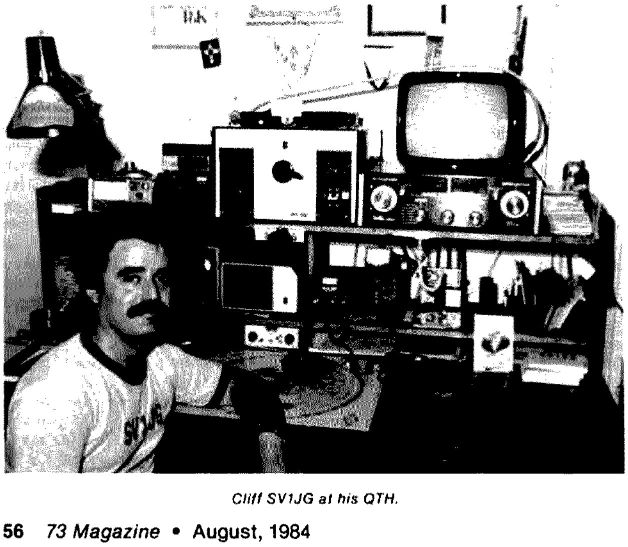
Visitors to Hong Kong who wish to operate can obtain a license to do so in 30 minutes upon application at the Post Office! All that is required is to show your original license and passport and have a photocopy of these for their files. In the event that you would be a resident for more than 90 days, then a full local VS6 license would be issued. These privileges are granted to all license holders from countries with which the United Kingdom has reciprocal agreement.

During the first week of February, I had the privilege of operating once more in Macao, and in four days of operating I made 3360 QSOs, all on sideband. With the help of my host, Jose Sousa (now XX9WW), we put up dipoles on 40 and 80 meters, and from the pileups on these bands there is plenty of scope for more operating from Macao! Look out for a Japanese DXpedition to Macao for August 10th to 20th approximately.

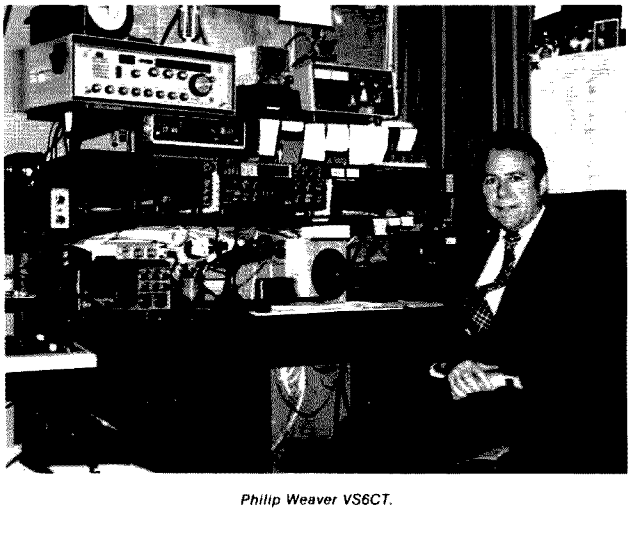
Interestingly enough, at this writing, nearly two months after the event, I have received only just over 700 QSLs. From this I am afraid that a lot of people will be sending their cards to a nonexistent QSL bureau. As is usual, they probably will end up in the Hong Kong Bureau. Although I am a member of HARTS, I can hardly inflict my outgoing CR9 cards on them. What it really amounts to is that education is needed by amateurs working DXpeditions. All have expenses such as transportation, hotels, QSL cards, and repairs to any equipment, in my case, to the borrowed linear.

So there are considerable outgoings which hopefully can be partly offset by incoming QSL cards with return envelopes and postage. Thanks to American amateurs who normally enclose a "green stamp" and Australians a "brown stamp," I shall just about break even, but what do I do with all those cards sent via the bureau? Two percent of the cards received direct have no envelope or return postage. I have actually spoken since to several of these latter stations, and without exception they have subsequently sent envelopes and postage. They had in every case just not thought about the problems at the other end.

I have, working as VS6CT over the last three years, made over 40,000 QSOs, and because of the problems with QSLing, established two QSL Managers—one in Japan (JA4ENL) and the other in England. If I had not done so, it would have brought into play the law of diminishing returns, for as the cards rolled in I would have spent less time on the air whilst filling them in. So what do you, the reader, want? If you want that VS6 or, for that matter, any rare card for your DXCC, please expect any rare DX station to have managers and always send a self-addressed enve-



Cliff SV1JG at his QTH.



Philip Weaver VS6CT.

lope with either 2 or 3 IRCs or a "green stamp."

One other aspect of operating from a fairly rare one is the different way one has to deal with the pileups. The Japanese are superb; you nave to call only one or two letters or work by prefixes and all others keep quiet until you have worked that station; they seem to know instinctively that more people can and will be worked that way. When working Japanese by prefixes I have worked 5 a minute, but that's quite hard going. Europeans never seem to learn, and the only way I have found to work them is by call areas, but still you get the breakers: "QRZ," "how about 3," "what's your QSL information," etc., instead of spending five or ten minutes listening.

Americans now seem very happy to work the last letter of their call, which I believe was introduced by "Uncle Bill" W7PHO on the family hour. This works extremely well, and I have found a very satisfactory rate of QSOs achievable this way.

73 and good hunting.

INDIA

India

ACTIVE AMATEURS OF INDIA

Indian amateurs have been doing lots of active work, like providing emergency communication at Morvi where a dam gave way killing lots of people, helping every year the Himalayan motor-car rally which starts from New Delhi and goes up to 16,000 feet on the Himalayan Mountains, and providing the only line of communication in Gujarat and Andhra Pradesh which gets hit very often by cyclones and very heavy rains and floods.

After watching what the amateur-radio operators of India are doing for the public, our government started taking interest in our world-famous hobby and has taken a very bold step I think no government in this world ever has.

On March 17, 1984, when Indians celebrate the Holi Festival days by throwing different color dyes on each other, our government made amateur-radio operators' lives more colorful by waiving custom duty for wireless apparatus, accessories, and components, when imported by a licensed radio-amateur operator, up to a value limit of Rs.10,000 (US$1000) in a financial year, per license, subject to certain conditions. A red-letter day not only in the history of Indian amateurs but also for hams 'round the world.

We Indian hams do know that we are short of foreign exchange, but still our government values services given by us. I hope that all my brother and sister hams will keep up the good standard of hamming in India and will not act in any way which will make our government think of us in a different way next year when the new import policy is made.

Amateur radio is coming up very rapidly in India due to the hard work of our educational groups which are sparing no effort in running classes free of any charges for amateur radio. In India we have a science center in most of the states which have enough space and means to run such classes.

In Bombay we have the well-known Nehru Science Center which has run ham classes since April, 1978, and lots of students from local schools as well as working and elder people from all classes of life have taken advantage of it. One of them was Commander Mody who is 75 years old and has just gotten his license. The classes are held in Bombay twice a week, where I take Morse code and VU2MPN takes theory. It takes about 20 weeks to get one ready for a Grade 2 exam (which is a Novice exam) where the student has to copy Morse code at 5 wpm and have a little knowledge of electronics. Once the student gets his Grade 2 license, he goes on the air on CW on all the bands and gets some good hams who help him to increase his Morse speed up to 12 wpm. Then with a little more theory, he goes for his Grade 1 exam.

There are many active clubs in India that take keen interest in getting students ready for ham exams. To name a few: the Amateur Radio Society of India in Delhi, the Radio Electronic Society of India (Bombay), the Bangalore Amateur Radio Club, and the Andhra Pradesh Amateur Radio Society.

Indian hams are made up not only of OMs, but YLs and XYLs also. They are doing quite a lot of DXing and it brings a little QRM into the OM life as some OMs have to cook their own breakfasts when the XYL is having her sked with another OM; it's also interesting when an OM has a bedroom shack and has a QSO with some YL and has to answer a question like, "What is this woman doing on the air so late in the night?" Hi. The poor XYL may not be knowing that the YL with whom her OM is talking is far away in W-land and it is 0800 local time! Hi.

It would be a grand idea if the YLs/XYLs would start a "kitchen net" and start exchanging good recipes. After the net, the YL/XYL could run into the kitchen to try the new dish and the OM could operate on the band without any XYL QRM.

There are many XYL/OM teams coming up here and some of the famous are VU2FC/CP, VU2KT/WW, VU2GI/UGI, VU2NNN/NYL, VU2MY/MYL, VU2GDG/his XYL/his daughter, and VU2DVP/CVP. These are just a few, as every day new ones are coming up.

Now slowly our hams are getting maritime mobile licenses, and there are a few operating from ships: VU2KZ, VU2UDD, VU2HSL, VU2LNN, and VU2FMB, and it is fun talking to our own boys from DX land.

There are very few hams on RTTY—at the moment, just two: VU2VIM (OM Vimal) and myself. Now that the import is allowed, we may find more hams coming up on this mode.

On OSCAR there is some work done by one, VU2RM, and he put India on the map of satellite communication. I was also doing my best as AMSAT area coordinator, but we are not able to work OSCAR 10 as we are not allowed to transmit on 70 cm, but we are now awaiting the license and I am sure very soon Indian hams will be on OSCAR 10.

Last but not least, the permission to operate the VU7 from Lakshdeep came as a surprise to all the hams over the world, and three groups operated for 15 days at a time. The last group led by VU2GDG did a wonderful job and I think now hams 'round the world have worked VU7 on all the five bands.

I am sure with all the encouragement given by our government now, India will not be a rare station in the world and there will not be more complaints that Indian hams are bad QSLers as now we have another QSL bureau which is run by me on behalf of the Federation of Amateur Radio Societies of India via Post Box 6538, Bombay 400026, India. This bureau is giving service to each and every ham 'round the world free of any charges. All expenses for running the bureau have been covered by the Federation for the last 15 years. I am real happy when I hear that now hams all over are having no problems in getting Indian QSLs; it gives me real pleasure that my work for the last 15 years was useful to everybody. I am very thankful my Federation has given me cooperation in running the bureau.

THE ASERET HAMFEST

For the past 35 years of its history, the Israel Amateur Radio Club has held only one national get-together a year—the annual general membership assembly of the association. Israeli law stipulates that all registered nonprofit organizations must have one such meeting a year to elect officers, and the declared purpose of the IARC annual assembly was to fulfill the letter of the law.

Over the years, our national association has grown from a handful of hams to over 700 members. In fact, the yearly meeting grew into a full-fledged convention squashed into one evening. It was no secret that most hams came primarily for the social get-together and the raffle of donated equipment, with the running of our organization being only an afterthought.

Last year it was decided to delete the raffle in order to give more time to the open "political" discussion and election of the executive. Needless to say, attendance dropped, and a past treasurer protested that the club's coffers had lost important revenue. The special-events committee met, and it was decided to try something new—a totally social event, a hamfest devoid of club politics, devoted entirely to enjoyment!

Thus, on Tuesday evening, March 27th, we gathered together at the community center of Aseret, a rural community half-an-hour's drive south from Tel Aviv. Amateurs came from as far away as Eilat on the Red Sea and the northern Galilee. There were visitors from the States, and the most exotic DX was a couple from the Philippines! For us all it was a great opportunity to make eyeball contact with those who up till then had been only voices coming forth from the loudspeaker.

Here in Israel no event is complete without opening speeches, but thankfully they were short and to the point. Aharon 4X4AT, IARC president, opened the program and thanked the various firms and individuals who donated prizes for the draw. 4X4GE of Motorola announced that his company was giving us space in one of their sites for our two-meter RTTY repeater. And the chief officer of the Israel Defense Forces' Signal Corps praised the technical perfectionism of the radio amateurs and hinted that surplus gear would continue to come our way.

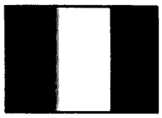
A fine and ample buffet, prepared by some of the amateurs and members of their families, ensured that no one went hungry and left early in search of a restaurant. Indeed, of all the IARC affairs I ever attended, this one had the best food! A program of entertainment with audience participation took place, although your scribe must confess that he took advantage of this time to meet with more hams.

The closing event was the long-awaited raffle. During the course of the evening, several volunteers had been going around hawking tickets at the shekel equivalent of a dollar fifty each. Our treasurer announced that we were now approximately two thousand dollars richer (or poorer, depending on how you look at it).

Prizes ranged from swr and power meters, mobile antennas, surplus "junk," and test equipment to a brand-new Lynx personal computer. There also were packages of cosmetics and artistic items for the ladies, and one gaudy statuette of a mermaid which was dubbed by Yankele 4X4AH, presiding over the draw, as an original microphone stand! Tickets continued to be pulled out of the bin, and a few "winners" failed to come forward to claim their boat-anchor Motorola D43GGV VHF transceivers which less than a decade ago were the mainstay of two meters in Israel.

The tension rose to its peak as the winning ticket was drawn for the microcomputer. I later learned that our lucky winner had bought no fewer than twenty-five tickets and had picked up a few other prizes in the process!

After saying good night to each other and thanking the organizers of the evening, we headed for the parking lot and began making our way back to our respective locations. No doubt, the Aseret hamfest had been an overwhelming success. Virtually all agreed that there's no need to wait a whole year before doing it again. Now, what remains to be seen, after all this, is what will be the nature of the upcoming general assembly of the IARC membership!



ITALY

Giancarlo Martelli I0XXR
Via Bevignani, 18
00162 Rome
Italy

One of the most enchanting tourist resorts in Sicily, the small town of Cefalu located near Palermo, hosted this year, April 8-13, the International Amateur Radio Region I Conference.

The honorary and practical task of organizing the event was undertaken by Associazione Radioamatori Italiani (ARI), and many important administrative and government agencies, recognizing the importance of amateur radio, gave their effective aid. Among them were the Sicily regional government, the official tourist agencies of Palermo, Trapani, Cefalu, Termini Imeresa, and Castelvetrano, and the Bank of Sicily and Fiat.

The special prefix IT84 was issued to all Sicilian ham stations, and during the conference the ARI official station worked from Cefalu with the call IP9IARU.

The meetings were held at the Hotel Club Costa Verde, a big and futuristic holiday center which hosted also the delegates of the Region I associations and all the guests attending the conference.

It is very important to note that such an important conference took place in Italy, a country where amateur radio recently suffered heavy attacks, as the readers already know. ARI and the associated groups promoted widespread publicity (state television, RAI, transmitted a spot on the event in the Telegiornale, the most popular news transmission) and obtained attendance by the Republic President,

Pertini, and by the Ministero Poste e Telecomunicazioni (MPT), the very same telecommunications administration which had been accused of being an enemy of amateur radio!

Moreover, the highest officials of the MPT, in the persons of the General Manager, Dr. Monaco, and the Central Director of the Radio Services, Dr. D'Arnore, attended the opening and declared officially the Italian government's goodwill toward the Amateur Radio Service.

At the conference was an important group of observers including the IARU president, W1RU, the ARRL president, W4RA, and the JARL president and secretary who represented IARU Region 3. For the first time in amateur-radio history, three European Ministries of Telecommunications, West Germany, the Netherlands, and Italy, had their technical observers officially attending the conference.

All this represents a further step ahead in the campaign of the amateur community to support the IARU with the primary intent of promoting our activities and defending our interests against the increasing appetites of other services. The presence of three official state observers, moreover, is evidence of an increased concern of the states as far as the cultural, technical, and social importance of our service is concerned.

Beyond the technical conclusions of the conference, it is paramount to underline the political importance of the above-noted presences of officials. It means that radio amateurs have obtained respectability and fair contractual power for discussing problems and needs and sustaining their rights and privileges. This power shall be enhanced with the good behavior of every one of us, operating our own radios, working for technical progress and for the social welfare, and supporting our associations. In fact, "association" means union of efforts and thus means power.

At the conference were present 32 associations—Algeria, Andorra, Austria, Belgium, Czechoslovakia, Denmark, Finland, France, West Germany, East Germany, Jordan, United Kingdom, Ireland, Israel, Italy, Liberia, Luxemburg, Malta, Monaco, Nigeria, Norway, the Netherlands, Oman, Poland, S. Marino, Sierra Leone, Spain, South Africa, Sweden, Switzerland, Hungary, and the USSR. Bahrain, Zimbabwe, and Djibouti sent proxies.

The technical work was carried out by three committees, A, B, and C, which issued at the end their recommendations, which will become official law for the self-governing amateurs in the IARU Region 1. Arguments with these recommendations are many, and I will try to recall only some of them.

Among the most important are the international beacon project, radio direction-finding activity, the promotion of amateur radio in developing countries, a common license project, piracy on amateur bands, standardizing of QSL cards, special callsigns and recommendation to limit their use, RTTY, AMTOR, and ASCII, bandplans, satellites, and 432-MHz repeaters' standard frequencies.

At the time of writing these lines, the situation hasn't changed much recently. The MPT has released the 160-meter band from 1.830 to 1.850 kHz (100 W out maximum) and the two higher new WARC bands and has given authorization to use 10 Watts on 144 MHz and up for mobile use. No resolution yet of the other controversial points: 3.5-MHz band, 10-MHz band, and the repeaters. Although the Post and Telecommunications Ministry has clearly demonstrated a much softer position toward amateurs' problems, it seems at present to be unable to move further. Bureaucratic obstacles seem to be stronger than the political will. It should also be considered that when the old law ruling radio amateurs was issued, that law ruled tightly many technical areas which, when updated, become quickly "illegal." So, as a law can be modified only by another law and due to the fact that in Italy a law often takes twenty or thirty years to be issued, the MPT is faced with the problem of satisfying the needs of amateurs by twisting amendments between the law lines.

Some conference observers: from the right, the JARL president, the ARRL president, the secretary, Region 2 (Colombia), the JARL secretary, and the ARI president.

In particular, as far as the repeater operation is concerned, the MPT understands that it is foolish to forbid a kind of operation which is of paramount importance in case of emergency, but bureaucracy says that any kind of repeater should pay a considerable annual tax (as a substitute for a land line); the tax amounts to some thousands of bucks per year—well beyond the ham's possibilities.

On the 3.5-MHz band problem, it appears clear that the MPT has already assigned parts and channels to other government agencies and seems unable to cancel these allocations without losing face; it offers to amateurs only 100 kHz. The amateurs oppose that mutilation of a band assigned to their service by ITU. On the same principles, the MPT offers amateurs only 10 kHz of the new 10-MHz WARC band, stating that on that band our service is only secondary and that in any case they should have the OK from the Defense Ministry. This reinforces the opinion that in the period when amateurs were neglected, the MPT let the military take the lion's part on this band and now they are unable to turn back.

LIBERIA

Brother Donard Steffes, C.S.C.

Brothers of the Holy Cross
St. Patrick High School
PO Box 1005
Monrovia
Republic of Liberia

Two hundred twenty-five inches of rain! That is a lot of rain for one year. It does not rain in January or February, but it gets very hot and then there is the Harmatan. The Harmatan is an atmosphere of fine dust that blows across Liberia from the Sahara Desert. It clouds the sky to an altitude of over forty thousand feet, and here on Earth it covers everything inside the house and out. I draped a heavy cloth over my radio equipment, but it did not escape. The dust did its job. It got into everything.

Here along the ocean (Monrovia is situated right on the shore of the Atlantic), we have salt spray all the time, but during the Harmatan season, the salt spray mixes with the dust and makes a grimy coating that covers all antennas, ground lines, coax cables, and anything else that is exposed to the outside air. When you turn on your radio, you find that the swr is up and the line noises are at a level that will curl your hair. I have a fourteen-thousand-volt power line passing about a hundred yards behind my TA-33 when it is pointed toward the States. The line noises go up to S8 and S9. I am not completely sure whether the blame should go to the salt spray-Harmatan combination or to the power line. Chances are that it is a combination of both. In any case, I do know that in March, when the rains begin, the frying, crackling noises go to zero.

Here in this part of Liberia we are dependent on hydroelectric generators for a great part of our power. As the dry season gets under way, the first thing we know the gates have to be closed to conserve water for the city supply; then the electrical power has to be rationed. We can use candles for light, but they will not power the radio, so we grief-stricken amateurs have another headache. A few of the stations operate on battery power, but that is another area that has its troubles.

The ionosphere has to get into the act, too. At least so it seems. During February I missed all my schedules. When there *was* power, the bands were so dead that one was lucky if he heard even one Brazilian station. Brazil has a direct line into West Africa. They are always there with signal strength that can override anything. Once in a while a station from England or Sweden will squeak through, but the United States might just as well not exist. I seldom operate at night, which here in Liberia would mean after seventeen or eighteen hundred Zulu. It may be that the night people working twenty meters fare better. Really, I don't think they fare much better.

Sometimes we get one or two heavy rains in March. The antennas get washed, the air becomes clear (one can actually see the shape of the sun), and if the ionosphere is there, the radio comes to life and one can communicate. In March, however, the respite is brief. The month is dry for the most part. In April it rains a little more. There will be an average accumulation of eleven inches. The electric company turns on one of its turbines and the antennas stay clean a bit longer. In May it gets down to serious raining and will run an average of twenty-five inches.

Please understand that all this is happening in Monrovia. Twenty-five miles out of the city in any direction, or even less than that, this whole situation would change. There would be no salt spray, the rainfall could be drastically different, and there might be no electric power at all.

In the data that I have gathered over a bit more than three years, June takes the cake. My records show an average of fifty inches for the month of June! July, August, and September will run about thirty inches each, and then the rains drop off with October (twenty inches) and September (fifteen). December is dry. It might accidentally rain in December, but it must be listed as a dry month.

I have found it very interesting to observe these happenings. While this can in no way pretend to be scientific, it has been fun to compile data, make charts, and compare records. I have no notable observations concerning radio communication during the times that the rains are very heavy. It is true that there are frequent periods of clear air and sunshine. It seldom rains continuously for more than a day. For the most part, radio communication is good and the amateurs walk around with smiles on their faces. Even people who are not amateurs smile. They like the rainy season, too. It is cooler.

SOUTHLAND FLOOD DISASTER

January in ZL-land is the middle of summer. Wednesday, January 25, was a fine hot day in Invercargill, the southernmost city in New Zealand, and all was well in the first week back at work after the summer holidays. The rain started at midnight, and on Thursday morning it was still raining. Nothing very unusual about that.

What was unusual was that the rain was to continue without slackening throughout the day. By 2100 hours NZST Thursday night, the Fire Service was involved in pumping water from flooded buildings and streets were being closed because of rising water levels, but so far the creeks and rivers were still within their banks. The flooding at that time was caused by an overloaded stormwater system. At 2315 it was still raining, and it seemed likely that those involved with Invercargill's Emergency Services would not get a full night's sleep.

At about 0315 hours, Friday the 27th, the AREC (Amateur Radio Emergency Corps) and Civil Defense Communications Leader, Neville Checketts ZL4OX, was summoned to CD HQ because a dec-

AMTOR How-To

FEC? ARQ? Don't panic. Timely advice from the father of AMTOR takes the confusion out of our newest mode.

The following text is from a letter to W2JUP from Peter Martinez G3PLX, dated 9/24/83, on the subject of AMTOR operating practices. This information is reproduced by express permission of the author and is offered as a guide to AMTOR operating rules, as suggested by the one man most responsible for bringing AMTOR into the amateur-radio fraternity. Newcomers to the AMTOR mode are invited to give serious consideration to the ideas presented here and to add these sections to whatever AMTOR equipment operating manuals they may have.

Here are some thoughts on the subject of operating rules, etc., for AMTOR. They are in no particular order and are written down exactly as they occurred to me as I sat in front of the typewriter. They represent aspects of AMTOR operating that have given rise to problems so far over here and some (the hot QSY technique) which have been invented to complement the advantages of AMTOR.

1. Legalities

Establish before operating whether you are authorized to do so. Most countries where there is currently AMTOR activity permit it by general license regulations. Some countries require the licensee to apply for a special permit. Some countries do not permit AMTOR. In others, stations are active.

2. Getting Started

The most popular AMTOR mode is ARQ, since it is the most effective. However, do not attempt to make the first QSOs on ARQ until FEC has been tested and is known to be working. If there is a fault in part of the system, no contact will result on ARQ at all, whereas at least if one direction (transmit or receive) is working, faults can be identified and cured with contact in FEC. The following step-by-step procedure will assist in finding faults during commission of a new AMTOR station.

2.1. Check FEC receive first, with a known distant station sending in the correct shift-polarity. This will confirm that the station receiver is working and in the correct shift-polarity.

2.2. Check FEC transmit next, asking a distant receiving station to confirm that the transmit shift-polarity is correct.

2.3. Make a short transmission with an ARQ call, asking the distant station to use "listen" or "monitor" mode to check that the transmitter keying is functioning correctly. The most common fault at this stage is a too-slow changeover from receive to transmit, resulting in missing transmitted data at the start of the burst. Some AMTOR units have a delay adjust which may allow slow transmitters to be used successfully except for very long distance contacts. Some remedial work may be required on the radio if this test fails.

2.4. If 2.3 is successful, ask the distant station to make an ARQ call to your selcal. Your station should respond and an ARQ contact should result.

2.5. Finally, make an ARQ call to the distant station and attempt an ARQ contact with your station as master rather than, as in 2.1, as a slave.

If no contact results yet the distant station indicates that he was replying to the call, then the problem is that the radio is too slow to change from transmit to receive. Remedial work may be required to correct this: No adjustment to the "delay" preset in the AMTOR unit, if fitted, will cure this problem. Consult the supplier of your radio if remedial work is needed. It is important to follow these steps in order. Unnecessary confusion, frustration, and interference can result from a premature attempt to start an ARQ contact where the complete contact cannot be made until all the component parts are working correctly.

3. Operating Techniques

AMTOR is sufficiently different from other modes that some of the operating practices traditionally used on the air are no longer appropriate, and some new techniques peculiar to AMTOR need explaining.

3.1. FEC and ARQ. When to use them. ARQ is well known to be the better of the two, but there are several situations where FEC has its advantages and some where its use is essential.

3.1.1. Use ARQ for all two-way contacts.

3.1.2. Use FEC for all multi-way contacts.

3.1.3. Do not use ARQ for CQ calls. There are several reasons for this:

3.1.3.1. Listeners cannot identify the calling station in an ARQ CQ call. Thus, they either must risk replying to a station with whom contact was not desirable or suffer the embarrassment of having to terminate a contact if, for example, it turns out to

be the station you have just worked.

3.1.3.2. If a contact which resulted from a CQ call on ARQ subsequently runs into a rephrase attempt, the resultant CQ call from the master station may attract a completely new reply from a third station, thus resulting in this new station "stealing" the contact.

3.1.4. FEC will have to be used if the distance between the two stations is longer than about 22,000 miles, such as in "long-path" contacts which travel more than halfway round the globe or some high-orbit satellite contacts. Make sure you know in advance if the path you are attempting is in this category, and do not attempt ARQ under these conditions; it is very frustrating to be called on ARQ when it is known that the path is too long and very difficult to attract the attention of the caller to the problem.

3.2. Starting an AMTOR QSO.

There is no need to explain how to start an FEC QSO since the technique is identical to that of other modes. However, since in ARQ mode it is necessary to know the other station's selcal code before calling him, a new technique must sometimes be required.

3.2.1. If the other station's selcal code is already known, as in the case of a "sked," then there is no problem. Simply enter the required selcal code to the AMTOR unit, and if/when the desired station is on frequency, he will reply and the contact can proceed.

3.2.2. If tail-ending on a previous contact and the intention is to call one station on ARQ and his selcal code is not known, then there are two ways to proceed:

3.2.2.1. There is a convention in operating amongst AMTOR operators with respect to the way to choose the station selcal code from the station callsign. This is to choose the first letter of the callsign followed by the last three letters, ignoring completely any figures. In the case of a callsign with only three letters altogether, the first letter is repeated twice. This ruse breaks down for callsigns in which the prefix contains figures. However, if the callsign of the desired station can be translated into a selcal code in this way, then use the selcal code to call him after he signs off with the station he is working.

3.2.2.2. If his callsign cannot be encoded in the above way or his callsign is now known or he does not respond to the expected selcal code, then call him in FEC mode, giving him the choice of calling you back on your selcal code or asking him to tell you what selcal code he is using. Note that some stations who may be using commercial SITOR-type units may not always be able to make ARQ calls to all possible combinations of letters in a selcal and thus may require that you call them, often with a selcal code that bears no relationship to their callsign, being in fact a translation from a telex number associated with the commercial equipment.

3.2.3. To make a CQ call to start an AMTOR QSO, do so on FEC mode, mentioning your own selcal code so that at the end of your call, a prospective QSO partner can call you back directly with your selcal. If you are expecting replies only on FEC (for example, for contacts via a long path), mention this fact in the CQ call.

3.3. Operating techniques whilst in contact in FEC.

Whilst operation in FEC is very similar indeed to that of conventional RTTY, there are two points to note, however, both related to the method by which the FEC receiver synchronizes the distant transmitter:

3.3.1. Since the receiver can only synchronize to the transmitter when it is not sending traffic (that is, idling), each transmission must start with a period of idling. Most AMTOR units will ensure that a short period of idle precedes the typed message, but under poor conditions or where it may help the distant receiving station to tune in, extra periods of idle will help, both at the beginning of the transmission and also at periods during the transmission, in case interference may have resulted in the distant receiver losing synchronization.

Note that the practice common on conventional RTTY of transmitting a line of test message or RYRYRY to allow the distant station to tune in is actually counterproductive on FEC, since the distant receiver will not synchronize until the end of this test sequence and the idle signal itself is quite suitable for tuning purposes.

3.3.2. Some commercial SITOR-type units require a received FEC transmission to start with a carriage return and/or a line-feed signal. For this reason, and also to aid the formatting of any distant printer copy, always start an FEC transmission on a new line.

3.4. Operating techniques on ARQ mode.

3.4.1. Transmitter and receiver tuning.

An ARQ contact always starts with the master station making the initial call and the slave replying. Thus the frequency will have been chosen by the master station, and the slave station will have "netted" onto that. It often happens that an offset at either station will then result in the signal from the slave received at the master being a bit off tune. If the master station then readjusts his transceiver's main tuning dial to remedy this error, he will also offset his transmitter, probably putting his signal off tune in the distant slave's receiver. A never-ending series of readjustments can then take place.

The equivalent problem on other modes rarely causes trouble since the retune operations only take place each time the transmission is passed from one station to the other. However, with the "quick-break" operation of ARQ, such offsets can cause trouble. Thus a convention has been adopted among AMTOR operators to prevent this situation arising. This convention is that the master station must at all times keep his transmitter frequency constant. Thus if the master finds that the slave signal is not correctly tuned, he must adjust only his receiver frequency to remove the error, leaving his transmitter frequency untouched, by the use of the RIT control on the transceiver. The slave station, on the other hand, may, if he finds his receiver off tune, make a correction by adjusting both receiver and transmitter frequencies together by means of the main tuning dial. This convention prevents any offset from accumulating and is the frequency-domain analogue to the time-domain synchronization in which the master-station clock determines the phasing for the contact.

3.4.2. Changing frequency during an ARQ QSO.

Since both stations are "listening through," if there is some interference on the frequency or if a change of frequency is desirable for some other reason (for example, to clear a calling frequency), then both stations may wish to move together to another frequency. Whilst at first there may seem to be no reason to discuss such a simple operation, which is very common and easy to perform on any other mode, there are problems if a QSY is made in some ways in ARQ, and there are advantages in adopting a specific technique.

3.4.2.1. The easiest way of QSYing an ARQ QSO is to close down and restart it again on a new frequency, with the master station choosing the new frequency. This is referred to in AMTOR circles as a "cold" QSY. This technique is the preferred one when moving off a calling frequency and in other conditions where there is good copy between stations, so that an orderly close-down and start-up is anticipated.

3.4.2.2. If, however, the QSY is desired because of interference, then another technique is possible; if carried out in the right way, it can have decided advantages, but if carried out wrongly, it can cause problems and offense to other band users. This is referred to as the "hot" QSY technique.

In this, the master station, while in the rephasing mode, moves off the old frequency to the new one, and the slave then follows.

It is important, while the master station is doing this, for him to prevent his transmitter from radiating in order to prevent unintentional interference to other band users and also to disable the connection between the receiver and the AMTOR (in order to prevent unintentional "phantom sync" to any other ARQ signals which may be audible during the search for a new frequency). Such phantom sync will result in spillage of traffic from the QSO in progress, from the other QSO, or both. It can only be the master station that leads in a hot QSY. If the slave station were to attempt to lead a QSY, then, in the event that it was not successfully completed before the contact timed-out into a rephase operation, the slave would no longer be transmitting, and there would be no way for the slave to establish a new frequency without restarting as a master and thus losing some traffic.

3.4.3. Fixed-channel working.

Since it is possible to leave an AMTOR station in "standby" mode on a channel and for any other station to make a specific call to that station, a common practice in AMTOR is to monitor such a specific frequency. The question arises as to what exactly is the "frequency" of an AMTOR emission. There are, unfortunately, two different conventions in use; one more commonly used in amateur circles, and the other used universally by all non-amateur users.

3.4.3.1. The "amateur" convention says that an AMTOR signal (and indeed any FSK signal) is specified with reference to the frequency of the higher frequency tone in the pair. Thus, if a sked, for example, is prearranged to occur on 14,075 kHz, this is taken to mean that the two transmitted tones are on 14,075.00 and 14,074.83 kHz.

3.4.3.2. The "commercial" convention, also used increasingly by amateurs, says that the signal is specified with respect to the frequency of the imaginary center channel. Thus a signal said to be on 21,100 kHz will have one tone on 21,099.915 kHz and the other on 21,100.085 kHz, that is, 85 Hz either side of the nominal, rather than with one tone on and the other tone 170 Hz below the nominal. Note that it is assumed that the frequency shift is universally accepted to be 170 Hz.

Thus, in any specification of a "frequency" in connection with AMTOR working, due regard must be taken of the convention intended, at least until such time as one of these conventions is dropped in favor of the other.

Another factor is significant with respect to setting frequencies on the dials of SSB transceivers used on AMTOR with audio-freqency shift tones used. Since the tones will result in transmissions offset from the suppressed carrier frequency, the dial, which normally indicates the suppressed carrier frequency, will not read correctly. It will be necessary to add or subtract a fixed amount to the dial frequency in order to establish the actual frequency in use. For example, if the transceiver is in use on lower sideband, with audio-tone frequencies of 2125 and 2295 Hz, then, to operate on an "amateur" frequency of 14,075, the transceiver dial must be set to 14,077.125, that is, 2.125 kHz higher than the desired freqency. The two radiated tones will then be on 14,077.125 − 2.125 (14,075) and 14,077.125 − 2.295 (14,074.83). Other offsets must be used if a "commercial" channel is to be set up (2.210 kHz), and the offset will be in the other direction if upper sideband is to be used in the transceiver. The offset must be recalculated if the tone frequencies are different from those quoted.

Users of transceivers with an FSK connection must consult the transceiver handbook or supplier to establish if an offset has to be applied to the dial frequency. Even if the transceiver supplier indicates that no offset is needed, it will be necessary to establish if the "amateur" or "commercial" convention is implied or some other convention.

3.4.4. Use of the "over" or "break-in" facility.

In ARQ mode, it is possible, by use of the "over" or "break-in" facility, to interrupt the sending of the other station. This facility should be used with care and only in situations where it is essential to do so. The reason is that there are inherent reasons why recovery from such an interruption can result in garbled copy at one end of the contact, in particular in "figs" garble. If possible, wait until the other station is idling before breaking in, and if the other station breaks into your transmission, it will probably help to use the "clear buffer" facility, if such exists, to abort the later transmission of any unsent text which would be inappropriate to the new context of the break-in.

3.4.5. The AMTOR alphabet, like the RTTY alphabet, consists of two sets of 30 characters, with a switch made between them by two "shift" or "case" codes. One inherent result of this technique is that it is often not known which shift the distant receiving station is in at the commencement of the contact. For this reason, it is always good practice to send the appropriate shift code at the start of each contact, and indeed, at the start of each message and perhaps at more frequent intervals. With terminals encoded in teleprinter code, there are always two keys, labeled "letter" and "figures," and so it is simply necessary to hit the appropriate one of these keys as required.

However, on more modern terminals, these two keys may not exist, and the sending of the shift code may be hidden from the user. However, since the distant terminal could still nevertheless be in the wrong shift, there will always be the requirement to send the shift code at the start to prevent the distant receiver copying the first part of the text in the wrong shift. Consult the documentation with your AMTOR unit or terminal in order to establish how to do this if there is no "letters" or "figures" key.

4. Format of Selcal Code

Although the convention is to form the selcal from the callsign, some AMTOR units have the possibility to include any AMTOR character in the selcal. It is strongly recommended, however, that only the 26 letters A–Z are used in selcal codes.■

Picture-Perfect Audio Filters

Throw away that antique breadboard and scope. Let your Apple II peak and tweak a soft circuit instead.

Active audio filters are amazing devices. They seem to be incredibly powerful yet wonderfully simple. I have marveled often at the way a handful of components can seemingly work magic on audio signals. Best of all, they can be an easy home-brew project.

Anyone who decides to design and build one of these gems will find a major stumbling block, however. It is very difficult to determine the true frequency response of the filters. In the past, I have used two methods to plot the response curve for my designs. One method was to use a calculator to work my way through some horrendous transfer functions and then graph the results. In order to get a useful graph, you must do the calculations for twenty or thirty frequency values. This method is an excellent way to wipe out several evenings or a weekend.

A second method is to breadboard the design and then go to work with a signal generator, oscilloscope, and graph paper. While this method is less tedious, it has many of its own problems, such as the accuracy of the test equipment and components used in the circuit. Now there is a third alternative for finding the frequency response of active filters. If you have access to an Apple II computer, you can use the program described in this article.

The program I wrote generates a graph of the frequency response of your own custom filter designs.

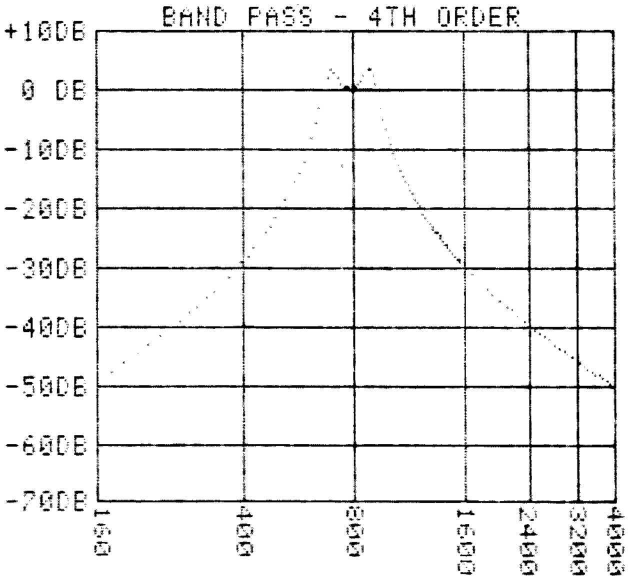

Fig. 1. Typical curve generated by the program. This is a two-section bandpass filter. The graph center frequency is 800 Hz and this was plotted in the wide mode.

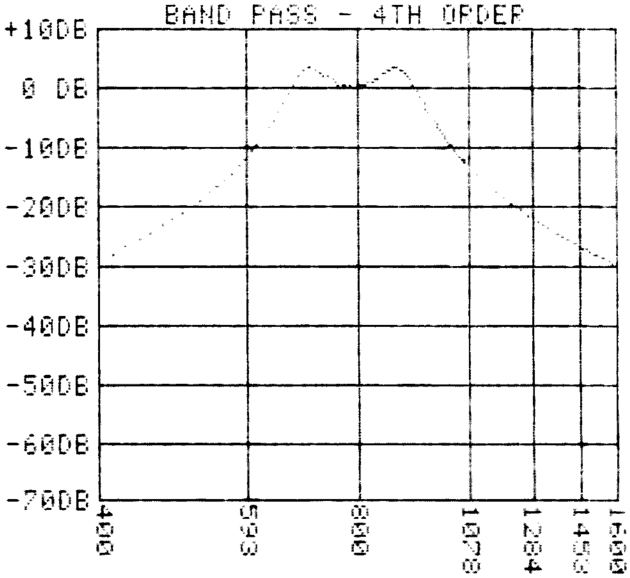

Fig. 2. The same graph as Fig. 1 but plotted in the narrow mode so that the central area can be examined. Note the horizontal frequency scale as compared to Fig. 1.

Shapefile.

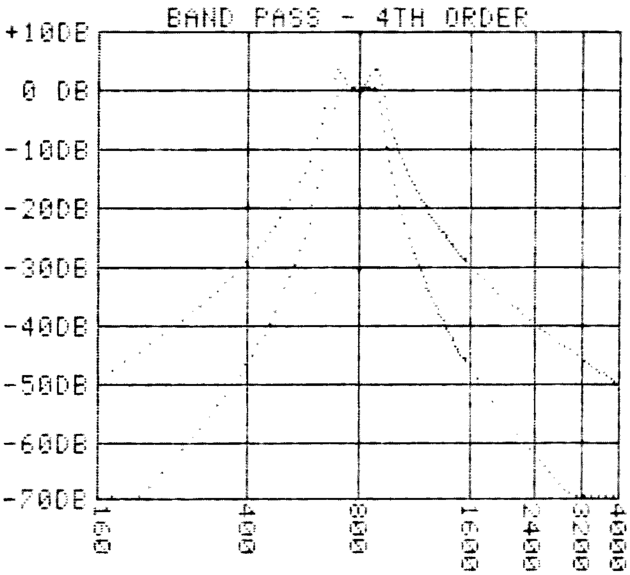

Fig. 3. The same graph as Fig. 1 but with a second filter curve plotted over the first using the overlay feature. The second graph is the same as the first with an additional section added to steepen the skirts and smooth the passband.

You input the cutoff frequency and Q of your design, and within seconds you get a graph for that exact filter. The graph shows the decibels of rejection as a function of frequency. The program can combine up to four cascaded filters and may be used for low-pass, bandpass, and high-pass designs. There are several other options that help make this a very powerful tool for those who enjoy tinkering with active filters.

The program uses the two HIRES screens in the Apple for the actual graphs. When you run the program, you will be presented with a menu where you select the type of filter in which you are interested (low-pass, bandpass, or high-pass). Next, you select the number of sections in your filter and then proceed to a data-input screen. This data-input screen is where you enter the various filter parameters for your filter and also select several graphing options. First you enter the center frequency, which is the frequency on which you want the graph centered. Next, you enter your filter's cutoff or center frequency and then its Q factor. If you are using a three-section filter, you enter the cutoff frequency and Q for each filter section.

After the filter information is entered, you are given several graphing options. First you select either a wide- or a narrow-frequency scale for the graph. The wide scale will generate a graph starting at 1/5th of the center frequency and ending at 5 times the center frequency. The narrow scale runs from half the center frequency to double the center frequency. As an example, if you select a center frequency of 1,000 Hz, then the frequency axis on the graph will go from 200 Hz to 5,000 Hz in wide mode and 500 Hz to 2000 Hz in the narrow mode. In both cases the graph will be centered on 1,000 Hz and will be logarithmic (see Figs. 1 and 2).

The second option is to select either HIRES page 1

✓ See List of Advertisers on page 98

or page 2. The last option available is the overlay mode. By selecting the overlay feature, you can have your graph plotted over a graph already in memory. This feature is especially useful for comparing two different filters (see Fig. 3). The third option also allows you to review any graphs already in memory. Using the review function also puts you back at the point where you select the three graphing options so that you can edit them before plotting the graph.

If you do use the review feature, you are presented with a new menu which lets you choose page 1 or page 2 simply by pushing the 1 or 2 key. You may toggle back and forth between the two in order to compare two graphs in memory. Pushing any other key will return you to the original menu. The review feature also is available from either of the first two menus.

Once you have opted for a new graph or an overlay, the program takes over and begins the plotting procedure. If you selected "new graph," then everything on the HIRES page you selected is erased and a new coordinate grid is calculated and drawn. If you selected "overlay," then the graph will be plotted over whatever graph and coordinate grid that is already in memory.

Next, the graph coordinates are calculated and plotted, and after the graph is drawn, you can return to the main menu by pressing any key. If you want to change the number of points that are plotted, then increase or decrease the STEP values in lines 1010 through 1090. I chose values which seem to give good trade-off between resolution of the graph and amount of time to plot the graph.

A few comments are in order concerning the graphs that are plotted. The equations in the program give the filter response as a ratio of voltages as opposed to current or power. The equations also give the theoretical response and do not allow for errors introduced by variations in component values or op amp limitations. As you increase the Q and number of sections in a filter, these items become more critical.

All of the coordinate grids display a range of 80 dB which converts to .5 dB for each screen pixel, which seems to be a reasonable resolution. You will find that the dB scale for the bandpass filters is different from the low-pass and high-pass. This was done to try to fit the maximum amount of information in the allotted room. The bandpass curves are set up so that the center frequency will always be 0 dB and all other points will be relative to it.

The low-pass is such that frequencies well below the cutoff frequency will be at 0 dB. High-pass is similar to low-pass, only it is frequencies above the cutoff frequency that are at 0 dB. This has been done by ad-

justing the gain in the calculations to place the curve on the graph where it provides the maximum amount of information. In real life if you build a filter, you can select whatever gain you like and it will have the effect of moving the entire curve up or down the vertical axis.

The program is in two parts, an Applesoft program and a shapetable file. The Basic program is entered in the normal fashion with the exception of lines 500 through 550 which must be entered without any spaces in order for them to fit into the Apple's input buffer. The program is heavily dependent upon subroutines, and care should be taken when entering line numbers to avoid branching errors. The shapetable is entered as described in the *Apple Reference Manual*, Chapter 3. The shapetable should begin at $6000, and it has a length of $304. After it is entered, BSAVE it using the filename FILTER SHAPEFILE.

If you have a graphics printer, you can easily add a routine to print the graphs. Add a line 295 to put the printer selection on the main menu. Add line 355 to read "IF T=6 THEN 1200". Starting at line 1200 you would add the printer routines used by your printer to output graphics. After the printing is complete, have the program return to line 220, the beginning of the main-menu sequence. I have used this method with the Epson MX-80, and it works.

I have included error trapping for most of the input for this program so that it usually will ignore an incorrect entry. However, you may run into a situation where you have managed to sneak some illogical character into a calculation which causes the program to error. If this happens, enter "RESET" and "RUN". You will be back at the main menu and any graphs in memory will be maintained intact. If you do not want to enter the program by hand, it is available from me on diskette (DOS 3.3) for $12.00.

If you have an interest in active audio filters and have access to an Apple computer, I am certain that you will find this program fascinating. The graphing routine gives you a very powerful tool to assist in designing filters. With the touch of a few keys, you can see exactly what response you can expect from a given design and a totally new filter may be evaluated in seconds rather than hours. This is the type of application where you can get some real utility from your micro. Good luck and happy filtering.■

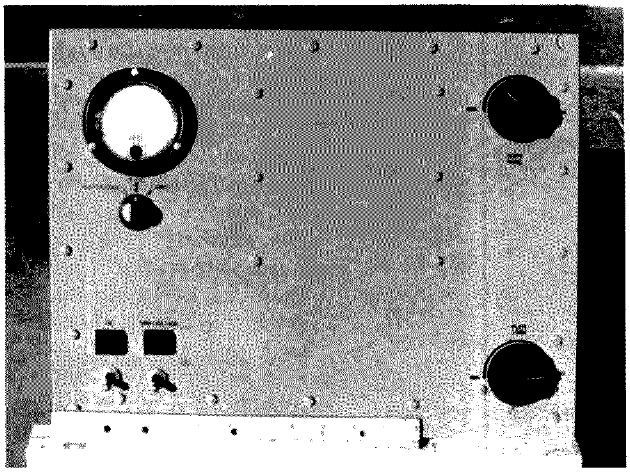
Top-Band Power Punch

Sick of S-2 reports on 160? Build this knockout kilowatt amp and make it 59 every time.



Front view of amplifier.

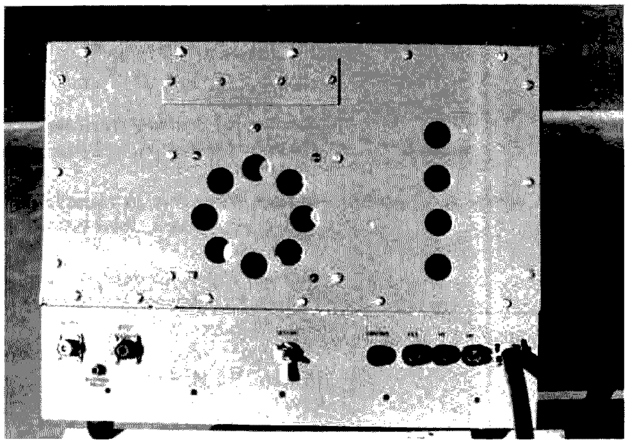
The addition of the 160-meter band to most amateur transceivers since the 60s has steadily increased interest in the "top band" to the point that it sounds like 75 phone during periods of good propagation. Often plagued by noisy atmospheric conditions and marginal antenna systems, this band is a prime candidate for an amplifier that will allow consistent communications.

With these considerations in mind, the AKF 160/1000 came about. (Its name is derived from the fact that it was built for my father, WØAKF. The "160/1000" is self-explanatory.)

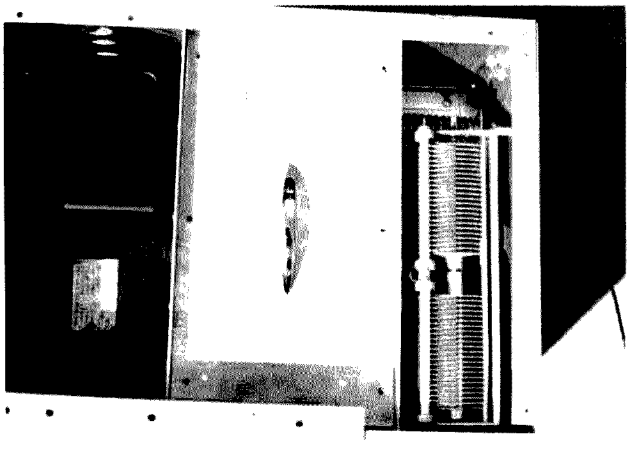
Primary design considerations for the construction of the 160/1000 were:

- single band—160 meters only
- low cost, using on-hand or readily available surplus parts
- must be "desk-top" and capable of 1 kW dc input
- tube(s) must be readily available and inexpensive

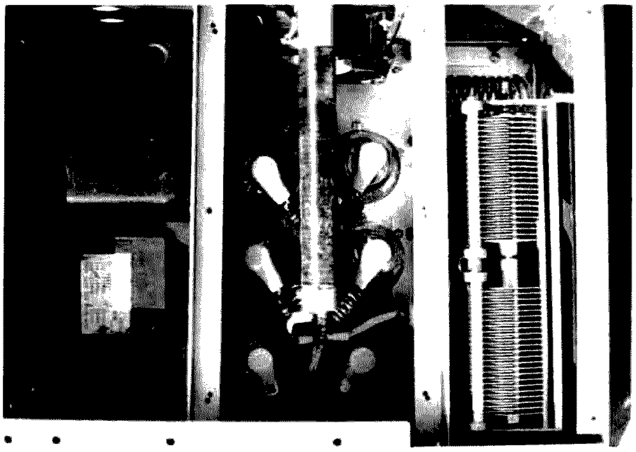
The final choice of tubes (811As) was primarily dictated by the above consider-



Rear view of amplifier showing intake and exhaust ports.



Top view of amplifier with tube chamber covered.

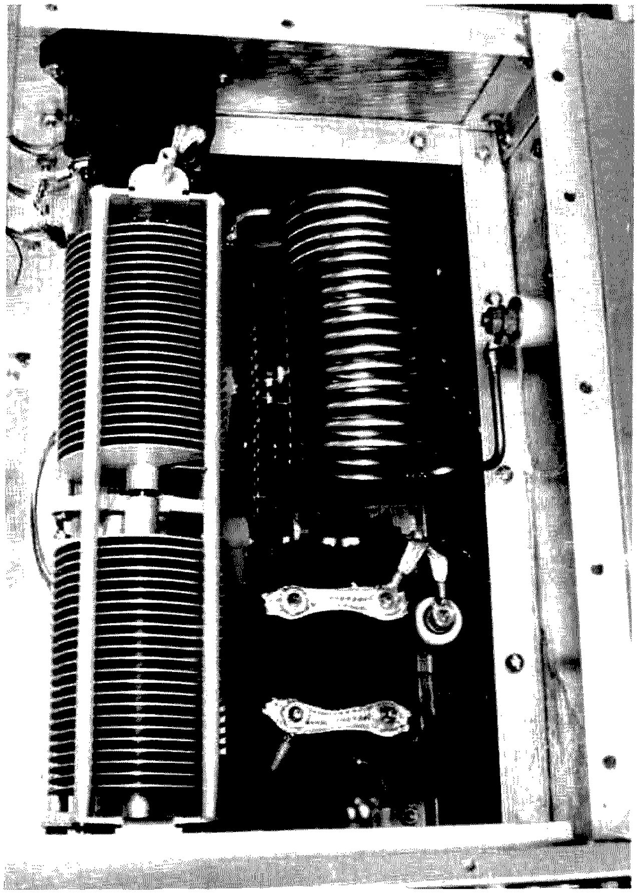


Top view of amplifier with tube chamber exposed. Note ZD1 in front of the filament transformer.

ations. Also, suitable filament and plate transformers were on hand. The venerable 811A triode has been used in many proven commercial and home-brew amplifier designs over the years and is still available—both new and used—for less than $15.00.

The circuit is a straightforward grounded-grid design using six 811As in parallel. I found that the input and plate-load impedances for a single 811A were 300 and 5k Ohms, respectively. This is equal to 50 and 833 Ohms, respectively, when six tubes are used in parallel. I found this to be desirable for several reasons:

- The 50-Ohm input Z would make it easy to drive with a solid-state transceiver, even with no tuned input circuit. (A 1:1 pi-net input was used anyway.)
- Although the 833-Ohm plate Z will result in high values of plate-tune and plate-load capacitances when looking into a standard pi-net, smaller variable capacitors are easily padded into the approximate tuning range by fixed values.
- The low plate Z also allows use of a smaller value of inductance which in turn saves space. (I tried several toroidal inductors but had difficulty with core heating—probably due to high current flow.)



Side view of amplifier showing the plate tune and pi-net coil. Note the Plexiglas sheet forming the near chamber wall, and also the surplus mica capacitors.

A single dual-movement meter with appropriate shunts was used for monitoring the three standard circuit functions. They are:

- plate current (0–1.5 Amps)
- grid current (0–1 Amps)

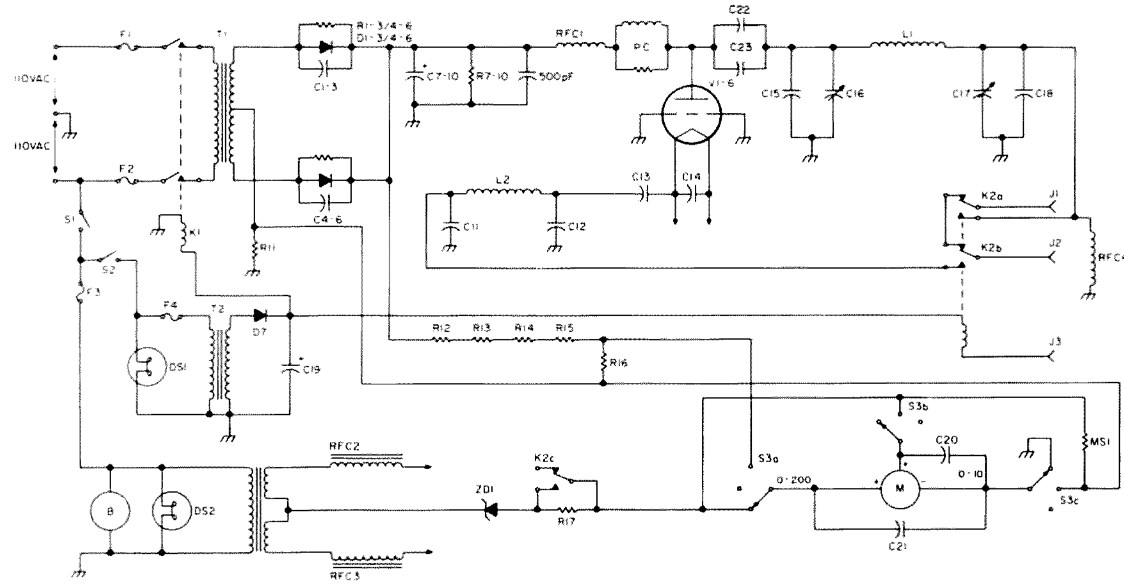


Fig. 1. Schematic.

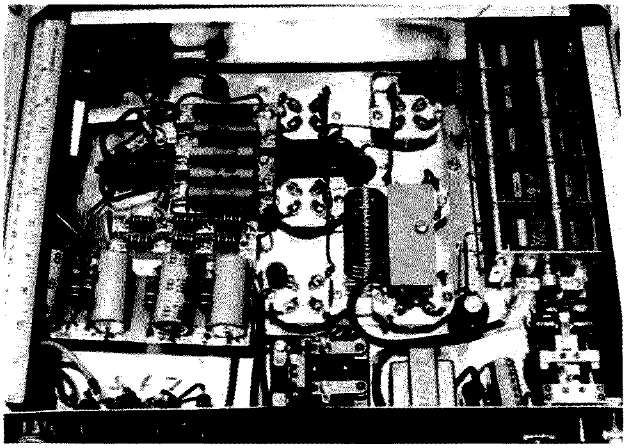

Under-chassis view of the amplifier. Left: power-supply components and HV-meter multiplier resistors. Center: tube sockets, filament choke, and input pi-net mounted on a standoff. Center bottom: ac power relay and 24-V-dc power supply. Right: input loading capacitor, antenna relay, and safety rf choke.

- high voltage (0–2 kV dc)

The metering can be modified to allow use of just about any low-cost or surplus instrument. In fact, separate meters for each function may be desirable.

Bias is developed in the center-tap return of the filament transformer by using a 6.2-V, 50-Watt zener diode. Zero signal plate I was found to be about 100 mA. Plate I is cut off during receive by resistor R17.

The power supply is a standard full-wave design and uses a surplus plate transformer rated at 500 mA CCS (available from Fair Radio Sales). Though it looks small, the transformer is very heavy and no excessive heating will occur.

Many component changes can be made to suit parts on hand as long as voltage ratings and values are observed. The main point is to not be afraid to experiment with different parts and layouts.

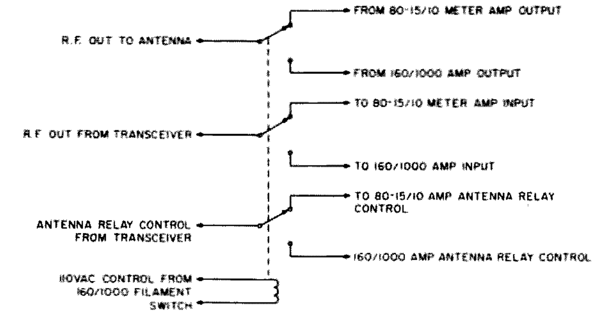

Fig. 2. Amplifier switching circuit for using two station amplifiers with a common antenna switching system. Alleviates cable swapping when going from one amp to another.

If your station already has an 80–15/10-meter amplifier, the circuit in Fig. 2 will allow automatic switching of rf and control functions between the two amps. This of course alleviates the cable-swapping behind the operating desk. It uses surplus DPDT power relays with 110-V-ac coils and is activated when the 160/1000 filaments are turned on. It was constructed in an aluminum minibox and placed near the station antenna switch.

Construction

The general layout and construction techniques I used should be evident from the photos.

Due to the low frequency, lead lengths are not as critical as they would be in the upper HF spectrum. However, your final layout should be such that leads are heavy, direct, and as short as possible.

I prefer using a commercial chassis as the amp foundation, then surrounding it with ⅛″-thick aluminum sheet held together with ¾″ aluminum angle and #8 or #10 hardware. Scrap aluminum sheet is fairly inexpensive, and when only straight cuts are required, the total cost of a heavy-duty rf-tight cabinet can be quite low.

Of special interest is the

Parts List

B	4″ muffin fan, 115 V ac	MS	meter shunt to match M above
C1-6, 13-14, 20-21	.01 μF, 1 kV disc	PC	parasitic choke: two 100-Ohm, 2-Watt carbon resistors in parallel with 4 turns #14, ½″ diameter
C7-10	100 μF, 450 V dc		
C11-12	3330 pF silver mica (three 1000s and one 330 in parallel)	R1-6	470k, 1 Watt
C15	.001 μF, 5 kV mica	R7-10	470k, 2 Watts
C16	1000 pF, 2 kV dc	R11	50 Ohms, 12 Watts
C17	2000 pF, 1 kV dc (receiver-type spacing)	R12-16	50k, 10 Watts
C18	.005 μF, 2.5 kV dc	RFC1	plate choke (370 turns #24 enamel on 1″-diameter hardwood dowel)
C19	1000 μF, 50 V dc		
C22-23	.002 pF, 5 kV mica block capacitors	RFC2	bifilar-wound filament choke (#10 enamel to fill 7½″ × ½″ ferrite rod—Amidon Assoc.)
DS1-2	115-V-ac pilot-lamp assembly		
F1-2	15 Amps		
F3	2 Amps	S1-2	SPST
F4	½ Amp	S3	3-pole/3-position rotary switch
J1-2	SO-239 coax jack	T1	115/115-V-ac primary; 2250-V-ac c-t, 500-mA secondary (surplus Collins Radio transformer from Fair Radio Sales #TF1UX02YY)
J3	RCA chassis jack		
K1	DPST or DPDT 25-Amp contacts/24-V-dc coil (surplus relay)		
K2	3PDT 10-Amp contacts/24-V-dc coil (surplus relay)	T2	115-V-ac primary; 24-V-ac c-t secondary (Radio Shack)
L1	17½ turns, #6, 2″ diameter	T3	115-V-ac primary; 6.3-V-ac c-t secondary, 24 Amps (Fair Radio Sales)
L2	17 turns, 1″ diameter, 2″ long		
M	surplus meter (0–200 and 0–10-mA movements)	ZD	zener diode, 6.2 V dc, 50 W, TO-3 case or stud mount

amplifier cooling. The six tubes are enclosed in a chamber formed of aluminum sheet and Plexiglas™ (the wall between the tubes and the pi-net is ¼" Plexiglas). Air is forced through the chamber using a standard muffin fan. A 1" gap in the front of the chamber top plate allows the air to move into the power-supply area. Four holes behind the plate transformer allow the air to exit the cabinet. This has the added effect of providing air circulation around the plate transformer.

Operation

This amplifier has room to spare when it comes to power output. Since the number of tubes and plate voltage may vary from amp to amp, no discrete tuning information is given. However, outputs in excess of 1100 Watts have been achieved when operating into a dummy load. I have found that tuning for maximum power output and then decreasing the drive level to the legal limit seems to give the best linearity. Check your metering and watch your signal on a monitor scope (the best piece of equipment a ham can have in his station). No evidence of flat-topping has been noticed, and the output appears to be a linear reproduction of the input when driven by a TS-830S at full power and viewed on the station monitor.

On-the-air comments have been excellent, with much interest expressed in the number and type of tubes. It is hoped that the 811A fanatics among you will add two more tubes and try construction of this amp. Good luck.

Special thanks go to my father, WØAKF, for his patience while I built this amp. The greatest reward is to hear him using it during our twice-weekly schedule. ■

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

situation by Tim. He's been making considerable progress, with several more licensed hams in immediate prospect . . . and more to come. Perhaps my talks are having some results? Old Doc Green gave the Computex opening-ceremonies address to a good-sized audience of Chinese businessmen.

My message for them is the same as for America—If Taiwan wants to be able to cope with the electronics revolution, it has to have engineers, technicians, and scientists to develop new products, to help make, sell, operate, and service them. Lacking technical people, Taiwan will have to just make do by copying the designs of others; they will always be two or three years behind.

And how does a country develop the needed technical people? Simple, really, just make sure that you expose kids 14 and 15 years old to high-tech hobbies such as amateur radio. It's no coincidence that Japan has ham-radio clubs in every high school in their country. They are, as a result, graduating seven times as many electronics engineers as the US, and with half our population! Thus, Japan has been able to take away virtually every consumer electronics industry from the entire world, including the US.

The electronics revolution has a long way to go, so there's still time for countries like Taiwan to develop the needed technical people and get in there and compete with Japan . . . designing state-of-the-art technical products and thus getting a good piece of the action. But without getting ham-radio clubs into every school on Taiwan, the country will be sentenced to copying—to stealing the ideas of others—as they have with their Chinese copies of the Apple and IBM computers and Rolex and Tiffany watches.

I've been giving this message in my talks to business groups in Taiwan for several years and I think the message is beginning to take. Now if I could only get some attention here in the US!

From Taiwan I went on to Hong Kong to see some more potential manufacturers and buy some goodies. The prices are best there for Sony, Seiko, and so on. The whole tour to four countries took just two weeks and got me back just in time for the Chicago Summer Consumer Electronics Show and then my yearly *USS Drum* submarine reunion.

Sherry was with me on the tour, going on to Manila from Hong Kong to see her suppliers. She imports some clever cloth and wire butterflies which she sells through gift shops and florists. She then met me in Mobile for the reunion, missing CES.

Now, about Taiwan and that DXpedition. My first thought was that it might be possible to work out something which would coincide with the October tour of Asian consumer electronics shows. I've been on that tour many times and will be going again this year. In two weeks, this gets you to electronics shows in Tokyo, Taiwan, Hong Kong, and Seoul . . . nine different shows in two weeks!

There are usually 200 to 300 on this tour, a good percentage of whom are hams, so it would be a natural if the DXpedition could be tied in with the tour. Unfortunately, with magazine deadlines taking so much time, there just wasn't enough time to get the word out, make all the ar-

$$ HOME-BREW III $$

Turn your hot solder into cold cash! Once again, *73* is searching for the greatest home-brewer in the land. All projects have a chance to appear in *73*, and the best of the best will be showered with fame and fortune.

Top prize is $250. Second place is worth $100, and three runners-up will each earn $50. Of course, this is in addition to the payment every author receives for publishing in *73*.

Contest Rules

1. Entries must be received by November 1, 1984.
2. To enter, write an article describing your best home-brew construction project and submit it to *73*. If you haven't written for *73* before, please send an SASE for a copy of our author's guide.
3. Here's the catch: The total cost of your project must be $73 or less, even if all parts were bought new. Be sure to include a detailed parts list with prices and sources.
4. Our technical staff will evaluate each project on the basis of originality, usefulness, reproduciblity, economy of design, and clarity of presentation. The decision of the judges is final.
5. All projects must be original, that is, not previously published elsewhere. There is no limit to the number of projects you may enter.
6. All rights to articles purchased for publication become the property of *73*.
7. Mail your entries to:

Attn: Home-Brew III

Dr. Green shaking a Model 100 computer at the Central New England College graduating class, threatening them with the coming need for a massive increase in communications in order to cope with the computer revolution.

Tim Chen BV2A wants you to come and DXpedition from Taiwan. How about it?

Some of the 1984 Computer Show Tour Group visiting a Korean computer factory.

Tokyo Disneyland is an immaculate must. A kid spilled some popcorn and within seconds three people appeared from nowhere and cleaned it up.

rangements, and have things in order bv October first.

I talked with Tim about the possibility of my bringing a repeater over and setting it up so that the American operator team could have good personal communications. Possible, but this will take some education of those in charge and some dickering. I talked with Bob Chang, who runs Commerce Tours, and he said he could arrange with the Ambassador Hotel for a safe place to set up the repeater.

We're going to have quite a ham contingent on the '84 October show tour, so I'd been thinking in terms of arranging for us to get HTs in Japan which we could use in Hong Kong and Korea. . . and perhaps even Taiwan. The turmoil of my merger with CW Communications and starting several new magazines and businesses scotched the HT plan for this year. Maybe in '85.

If about ten of you would be interested in getting over to see Tim and operating for about five or six days from Taipei next spring, drop me a line. I would estimate that the whole trip would cost about $3,000 which would include transportation, hotels, a week in Taiwan, plus a few days in Tokyo and Hong Kong. By then we may be able to work out the two-meter repeater and HT situation.

If I can get ten positive and a few more possible candidates for the DXpedition, I'll start Commerce on setting up the arrangements and start working with Tim to cover the legal formalities.

Have you ever wondered what it's like to operate from the heart of Asia? To get on from a rare spot and have the whole world beating your brains out for a contact? It's heady stuff. I've operated from some pretty rare spots and it's really addictive. Why leave all the real DXing to Lloyd and Iris?

Computer nuts will go right out of their minds when they see the prices for Apple- and IBM-compatible boards in Taipei. And almost every American computer book is available for a couple bucks, reprinted there.

The food is superb and the sights incredible, from their museums to Snake Alley. Your camera will be snapping day and night. So, are you game for a little DXpedition to the Republic Of China next May, running from about May 15th to 30th?

Who knows, between the Computex computer show in Taiwan and the products made in the People's Republic of China—which you can visit on the same trip, going up for a one-day visit from Hong Kong—you might find a product to import and distribute. That would make this a business trip, right?

Your wife? Why not? There's no shortage of things for her to see while you are busy filling your log with contacts. And a businessman really needs some sort of assistant on a trip like this. . . to get details and prices from manufacturers while you are DXing.

If you can get away for more than two weeks, for a few bucks extra you can return via some interesting places and maybe get in a few more days DXing. A little over a year ago I made the trip back from Hong Kong, stopping off to work DX from Bangkok, Singapore, Kuching (Sarawak), Bandar Seri Begawam (Brunei), Kota Kinabaiu (Sabah), and Manila. If you're interested in operating from any of these places, I can put you in touch with a local ham who will help you and perhaps even let you use his station for a couple of days. Brunei is a new country now. . . how about it?

Akihabara, made into a pedestrian mall on Sundays, is an electronics Mecca. There are hundreds of electronics, radio, and computer stores all in one part of Tokyo. Several American hams visiting here have tried to defect.

Some Chinese dinners are memorable! You won't forget your Taiwan visit.

SEP 8-9

The San Angelo Amateur Radio Club will hold CEN TEX HAMFEST '84 on September 8-9, 1984, in the San Angelo Convention Center. Tickets are $5.00 in advance and $6.00 at the door. Hours for Saturday are noon to 6:00 pm and for Sunday, 8:00 am to 2:00 pm. Special events for the ladies include a Saturday afternoon tour of Fort Concho and Old San Angelo. There will be seminars and group meetings Saturday afternoon and Sunday morning, and a reception for dealers followed by a social hour for amateurs on Saturday night. Talk-in on 146.34/.94. For pre-registration or hotel/motel accommodations, write CEN TEX HAMFEST '84, PO Box 3751, San Angelo TX 76902.

MELBOURNE FL
SEP 8-9

The Platinum Coast Amateur Radio Society will hold its 19th annual hamfest and indoor swap-and-shop flea market on September 8-9, 1984, at the Melbourne Auditorium. Admission is $3.00 in advance and $4.00 at the door. Swap tables are $10.00. There will be food and plenty of free parking available, as well as awards, forums, and meetings. Talk-in on .25/.85 and .52/.52. For reservations, tables, and more information, write PCARS, PO Box 1004, Melbourne FL 32901.

TORRINGTON CT
SEP 9

The CO Radio Club will hold its hamfest on Sunday, September 9, 1984, from 8:00 am to 4:00 pm, at the Torrington Retirees Drop-In Center, East Albert Street. Admission is $2.00, tables are $7.00, and the fee for tailgating is $5.00. Talk-in on 146.05 and 147.24. For more information, write Donald D. Taylor KA1GKJ, PO Box 455, Watertown CT 06795.

MONETT MO
SEP 9

The Ozarks Amateur Radio Society will hold the 3rd annual Ozarks Amateur Radio Club Congress and Swapfest on Sunday, September 9, 1984, beginning at 11:00 am, at the Monett City Park, junction of highways US 60 and MO 37, Monett MO (between Springfield and Joplin). There is no

admission charge and no charge for swap space (available on a first-come, first-serve basis). The buffet dinner begins at 1:00 pm (bring a single covered dish and share in the feast). Talk-in on the 146.37/.97 repeater and 7.250 MHz. For more information, contact the Ozarks Amateur Radio Society, Box 327, Aurora MO 65605.

CARTERVILLE IL
SEP 9

The Shawnee Amateur Radio Association will hold its 28th annual hamfest on September 9, 1984, at the John A. Logan Junior College Campus, Route 13 west, Carterville IL (6 miles east of Carbondale). Admission is $3.00 and flea-market tables are free. Activities will include forums, ladies events, and lunch served on the campus. There will be camping available across the road, motels nearby, and plenty of free parking. Talk-in on 3.925 from 8:00 am to 9:00 am and on 146.25/.85. For more information, phone Bill Johnson W9ERI at (618)-457-7586.

GRAND RAPIDS MI
SEP 15

The Grand Rapids Amateur Radio Association, Inc., will hold its annual Swap and Shop on Saturday, September 15, 1984, beginning at 8:00 am, at the Hudsonville Fairgrounds. There will be dealers, a concession, an indoor sales area, and an outdoor trunk-swap area. Talk-in on 146.16/.76. For more information, write Grand Rapids Amateur Radio Association, Inc., PO Box 1248, Grand Rapids MI 49501.

PEORIA IL
SEP 15-16

The Peoria Area Amateur Radio Club will hold its Peoria Superfest '84 on September 15-16, 1984, at the Exposition Gardens, W. Northmoor Road, Peoria IL. The gate opens at 6:00 am and the Commercial Building at 9:00 am. Admission is $3.00 in advance and $4.00 at the gate; children under 12 will be admitted free. Activities will include amateur-radio and computer displays, a huge flea market, a free bus to Northwoods Mall on Sunday, and a Saturday-night informal get-together at Heritage House Smorgasbord, 8209 N. Mt. Hawley Road, Peoria IL. There are full camping facilities on the grounds. Talk-in on 146.16/.76 (W9UVI). For reservations and more information, send an SASE to Superfest '84, PO Box 3461, Peoria IL 61614.

MT. CLEMENS MI
SEP 16

The L'Anse Creuse Amateur Radio Club will hold their 12th annual swap and shop on Sunday, September 16, 1984, from 9:00 am to 3:00 pm, at the L'Anse Creuse High School, Mt. Clemens MI. Take I-94 eastbound to the Metropolitan Parkway exit; then take the Metropolitan Parkway to Crocker; turn left on Crocker to Reimold and then right on Reimold to the last school, L'Anse Creuse High School. Admission is $1.00 in advance and $2.00 at the door. FCC representatives will be there, as well as plenty of new and used gear. There will be lots of food and parking. Talk-in on 147.69/.09 and 146.52. For more information, send an SASE to Maurice Schietecatte N8CEU, 15835 Touraine Court, Mt. Clemens MI 48044, or phone (313)-286-1843.

NEW KENSINGTON PA
SEP 16

The Skyview Radio Society will hold its annual hamfest on Sunday, September 16, 1984, from noon until 4:00 pm, at the club grounds on Turkey Ridge Road, New Kensington PA. Registration fee is $2.00 and vendors' fees are $4.00. Awards will be presented. Talk-in on .04/.64 and .52 simplex.

AUGUSTA GA
SEP 16

The Amateur Radio Club of Augusta will hold its annual hamfest on September 16, 1984, at Julian Smith Casino Park. Tickets are $1.00 each, 6 for $5.00, or 13 for $10.00. Features will include a flea market in the parking lot, a barbecue, refreshments, dealers, entertainment, and on Saturday evening, a hospitality room at Ramada Inn West, Washington Road, rooms 108-110. Talk-in on 145.49 – 600. For more information, send an SASE to D. F. Miller WB4YHT, Hamfest Chairman, 4505 Shawnee Road, Martinez GA 30907, or call 1-(404)-860-3700.

GRAYSLAKE IL
SEP 22-23

The Chicago FM Club will sponsor Radio Expo '84 on Saturday and Sunday, September 22-23, 1984, at the Lake County Fairgrounds, Rtes. 120 and 45, Grayslake IL. Tickets, good for both days, are $3.00 in advance and $4.00 at the gate. The flea market will open at 6:00 am and the exhibits will open at 9:00 am. There will be a giant outdoor flea-market area. Reserved indoor flea-market tables are available for $5.00 per day. Other features will include seminars, technical talks, ladies' programs, and free parking and overnight camping. Talk-in on 146.16/.76. For more information, send an SASE to Radio Expo '84, Box 1532, Evanston IL 60204, or phone (312)-582-6923.

VIRGINIA BEACH VA
SEP 22-23

The 1984 ARRL Roanoke Division Convention and 9th annual Amateur Radio/Computer Fair will be held on Saturday and Sunday, September 22-23, 1984, from 9:00 am to 5:00 pm both days, at the Virginia Beach VA Pavilion. Admission for both days is $4.00 in advance and $5.00 at the door. Flea-market tables are $5.00 for one day and $8.00 for both days. Features include dealers, special displays, forums, computer equipment, a giant flea market, free XYL bingo, and movies for the kids. For tickets and more information, write Jim Harrison N4NV, 1234 Little Bay Avenue, Norfolk VA 23503, or call (804)-587-1695.

WICHITA FALLS TX
SEP 22-23

The annual Wichita Amateur Radio Society Tornado Alley Hamfest will be held on Saturday and Sunday, September 22-23, 1984, at the National Guard Armory, Wichita Falls TX. The hours on Saturday will be 9:00 am to 5:00 pm and on Sunday, 9:00 am to 2:00 pm. Registration will begin at 9:00 am both days and is $4.00 per person in advance and $5.00 at the door. Pre-registration closes Wednesday, September 19th. There will be a large indoor flea market and tables are $3.00 each. Features will include commercial dealers' displays, computer dealers and demonstrations, ladies' activities, and special events. If you wish to take an amateur exam, send FCC form 610 to the hamfest address prior to August 17, 1984. A concession stand will be open both days. Talk-in on 146.34/.94, 147.75/.15, 449.30/444.30, and 449.20/444.20. For more information or pre-registration, contact WARS Hamfest, PO Box 4363, Wichita Falls TX 76308.

GAINESVILLE GA
SEP 23

The 11th annual Lanierland ARC Hamfest will be held on September 23, 1984, beginning at 9:00 am, in the Holiday Hall at Holiday Inn, Gainesville GA. There will be free tables and an inside display area for dealers reserving in advance. A large parking lot will be available for the free flea market. Other features will include a left-foot CW contest, a ladies' country store, and many activities. Talk-in on 146.07/.67. For more information and reservations, contact Phil Loveless KC4UC, 3594 Thompson Bend, Gainesville GA 30506, or call (404)-532-9160.

WICHITA KS
SEP 23

The Wichita Hamfest will be held on September 23, 1984, at Camp Hiawatha, 1701 West 51st Street North, Wichita KS 67204. Features will include a flea market, programs, and commercial exhibits. For more information, contact Norm Tramba WA8HWH, 340 S. 1st, Clearwater KS 67026, or phone (316)-584-6425.

WILLIMANTIC CT
SEP 23

The Natchaug Amateur Radio Association will hold its annual giant flea market on Sunday, September 23, 1984, from 9:00 am to 4:00 pm, at the Elks Home, 198 Pleasant Street (off Route 32), Willimantic CT. Admission is $2.00 and children under 16 will be admitted free. Tables are $5.00 in advance and $7.00 at the door (dealers will be admitted at 8:00 am). Food, drinks, and free parking will be available. Talk-in on the 147.30/147.90 repeater and .52 direct. For more information, contact Ed Sadeski KA1HR, 49 Circle Drive, Willimantic CT 06226, or phone (203)-456-7029.

ADRIAN MI
SEP 23

The Adrian Amateur Radio Club will hold its 12th annual hamfest on Sunday, September 23, 1984, at the Lenawee County Fairgrounds, Adrian MI. Because tables are limited, reservations (by check or cash) must be made no later than September 15, 1984. For more information, tickets, or tables, contact Adrian Amateur Radio Club, PO Box 26, Adrian MI 49221.

HAMILTON ONT CAN
OCT 6

The Hamilton Amateur Radio Club, Inc., will hold its 2nd annual flea market on Saturday, October 6, 1984, beginning at 8:30 am, at Marritt Hall, Ancaster Fairgrounds, 625 Highway 53 East. Admission is $2.00. Flea-market vendors' 8-foot tables are $4.00 plus admission and commercial vendors' 8-foot tables are $10.00 with admission included. There will be room for 150 vendors and setup will be from 7:00 am to 8:30 am. Coffee, soft drinks, and sandwiches will be available. Talk-in on 146.16/146.76 (VE3NCF). For space reservations, contact HARC Flea-Market Committee, PO Box 253, Hamilton ONT L8N 3C8. For more information, contact Stan VE3GFE on VE3NCF.

SANTA FE NM
OCT 7

The Northern New Mexico Hamfest will be held on October 7, 1984, from 8:00 am to 3:00 pm, at the Terrero Group Shelter, along the Pecos River, east of Santa Fe. Admission is $3.00 for adults and $1.50 for children. Activities will include a tailgate flea market, group meetings, family games, fishing, and picnicking. There will be hot dogs, chips, soft drinks, and coffee available, as well as free Saturday-night camping. Talk-in on local repeaters and .52 simplex. For further information please send an SASE to Northern New Mexico ARC, c/o Bob Norton N5EPA, Route 3, Box 95-15, Santa Fe NM 87501, or call on 3.939 MHz at 0100 UTC.

YONKERS NY
OCT 7

The Yonkers Amateur Radio Club will sponsor the Yonkers Electronics Fair and Giant Flea Market on Sunday, October 7, 1984, from 9:00 am to 4:00 pm, rain or shine, at the Yonkers Municipal Parking Garage, corner of Nepperhan Avenue and New Main Street, Yonkers NY. Admission is $2.00 each and children under 12 will be admitted free. Gates will be open to sellers at 8:00 am and there will be a $6.00 admission per parking space which will also admit one (bring your own tables). Refreshments, free parking, and sanitary facilities will be available, as well as unlimited free coffee. There will be live demonstrations all day and a giant auction at 2:00 pm. Talk-in on 146.265T/146.865R or .52 direct. For more information, write YARC, 53 Hayward Street, Yonkers NY 10704, or phone (914)-969-1053.

PARAMUS NJ
OCT 14

The Bergen ARA will hold a Ham Swap 'n' Sell on October 14, 1984, from 8:00 am to 4:00 pm, at Bergen Community College, 400 Paramus Road, Paramus NJ. There will be tailgating only; bring your own table. Admission for sellers is $4.00; buyers will be admitted free. Thousands of spaces will be available. Talk-in on .79/.19 and .52. For more information, write Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855, evenings only.

HAM HELP

Tornado and/or thunderstorm-detection article from very early *73* magazine needed. Will be happy to pay any reasonable copy costs. Will also pay copy costs for any other electronics articles on the same subject.

Jim Weir WB6BHI
13281 Grass Valley Ave.
Grass Valley CA 95945

I am looking for the service manual for the NCX-3, or schematics for the power supply for the NCX-3 (by National).

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

THE POSTMAN GETS RELIEF

This year's FUN! Poll, the fourth annual installment, saw our postman get some much needed rest. The acquisition of PO Box 73 and the use of electronic mail meant that my friendly mail carrier didn't have to suffer this year with a heavy mail sack and icy sidewalks.

Response levels were down this time. In 1983, 1,190 hams wrote in to express their views. This year, 987 of you mailed or electronically transmitted your responses. Still, that's a significant amount of mail to open, read, and tabulate. It took four people to accomplish the manual work and five computers (a TRS-80 Model III, an Apple IIe, an Atari 400, and a TRS-80 Model 100) to manipulate the numbers. Mainframe computers in Columbus, Ohio, and McLean, Virginia, transmitted the electronic responses to FUN! HQ.

Here's what you had to say.

ELEMENT 1 BACKGROUND

1) Sex:
A) Male—97%
B) Female—3%
No surprise here.

2) Age:
A) 15 or below—3%
B) 16-21—5%
C) 22-39—27%
D) 40-59—38%
E) 60 or above—27%
The graying of amateur radio. These numbers are heading upward with each poll.

3) License class:
A) Novice—8%
B) Technician—12%
C) General—31%
D) Advanced—39%
E) Extra—10%
Somehow, I expected more Extras to respond.

4) Number of years licensed:
A) 1 year or less—2%
B) 1-5 years—31%
C) 6-10 years—13%
D) 11-20 years—32%
E) 21 years and up—22%
Just about the same statistics as last year.

5) Do you have a new (post-March '78) call?
A) Yes—52%
B) No—48%
The "yesses" break the 50% mark for the first time.

6) How many hours a week do you devote to amateur radio?
A) 0-1 hour—8%
B) 2-5 hours—35%
C) 6-10 hours—33%
D) 11-20 hours—19%
E) 21 hours or more—5%
Activity seems down a bit from last year.

7) Which HF band do you use most?
A) 80-75 meters—17%
B) 40 meters—25%
C) 20 meters—21%
D) 15 and/or 10 meters—24%
E) Don't operate HF—13%
About the same numbers as last year. Next time, we'll include the WARC bands.

8) Which VHF-UHF band do you use most?
A) 6 meters—2%
B) 2 meters—74%
C) 220 MHz—6%
D) 420 MHz and/or up—4%
E) Don't operate VHF-UHF—14%
Also about the same.

9) Which mode do you use most?
A) SSB—42%
B) CW—18%
C) FM—31%
D) RTTY—5%
E) Other—4%
Same again.

10) How much money have you spent on amateur radio within the past year? (Include QSL expenses, magazine subscriptions, club dues, and other incidental expenses.)
A) 0-$250—51%
B) $251-$500—30%
C) $501-$1,000—13%
D) $1,001-$2,500—4%
E) $2,501 and up—2%
The economy is up, but ham sales are still down.

ELEMENT 2 SOCIAL CHARACTERISTICS

11) Has amateur radio influenced your career choice?
A) Greatly—24%
B) Somewhat—22%
C) Not at all—54%
Less of an influence than last year.

12) Should the ARRL get rid of the DXCC Honor Roll?
A) Yes—61%
B) No—39%
Sending a message to Newington.

13) Politically, how would you define yourself?
A) Conservative—51%
B) Middle-of-the-road—48%
C) Liberal—3%
We're getting more conservative.

14) Should the ARRL get rid of the DX Century Club?
A) Yes—51%
B) No—49%
We're split.

15) How old were you when you first became a ham?
A) 15 or below—13%
B) 16-21—50%
C) 22-39—21%
D) 40-59—11%
E) 80 or above—5%
No significant change from last year.

16) Should the FCC increase the speeds on amateur CW examinations?
A) Yes—13%
B) No—87%
Shaky fists.

17) Do you own a home computer?
A) Yes—55%
B) No—45%
We've broken the 50-percent barrier! Who would have thought it, only a few years ago?

18) Do you think hams, compared to computer hobbyists, are:
A) More technically inclined in their hobby—26%
B) Less technically inclined in their hobby—38%
C) About equally skilled in their hobby—36%
Not much change here.

19) Do you think that home computing is siphoning people (including youngsters) away from amateur radio?
A) Yes—60%
B) No—40%
If you don't believe this, you're kidding yourself.

20) Will the volunteer exam system increase cheating?
A) Yes—45%
B) No—55%
Not exactly a vote of confidence.

21) Should volunteer examiners be allowed to collect a fee to help defray expenses?
A) Yes—71%
B) No—29%
And the FCC agrees.

22) Has ham radio helped to make you a better person?
A) Yes—75%
B) No—25%
That's nice.

23) Should ham licenses have a minimum age requirement?
A) Yes—45%
B) No—55%
Oh, pooh to you 45 percenters. You want to kill the hobby, or what?

24) Should hams be subject to periodic retesting?
A) Yes—6%
B) No—94%
Ah, we all remain confident in our skills.

ELEMENT 3 OPERATING HABITS

25) If the users were restricted to data communication only (no phone or CW operation), would you be in favor of a no-code 220-MHz, digital-class license?
A) Yes—43%
B) No—57%
I guess 220 is too busy as it is.

26) Would you be in favor of a no-code 220-MHz, digital-class ticket if it permitted phone operation in addition to data transmission?
A) Yes—6%
B) No—94%
I hear you, I hear you!

27) Have you ever used a personal computer in connection with your amateur-radio activities?
A) Yes—70%
B) No—30%
Up 11 percent from last year. A very good sign.

28) Is it time to completely deregulate amateur radio by having the FCC turn over all responsibility for ham operation to the amateur community?
A) Yes—55%
B) No—45%
Exactly the same numbers as last year. I guess we still don't totally trust ourselves.

29) What do you think of people who view pay-television services with MDS converters and satellite dishes that are not approved by broadcasters?
A) They're skunks—37%
B) They're within their rights—63%
Okay.

30) Should we get rid of, or reduce in size, the CW subbands?
A) Yes—61%
B) No—39%
No big change here.

31) Do you think DX nets have a place in ham radio?
A) Yes—34%
B) No—66%
Let's dump 'em.

32) Do you think nets in general have a place in ham radio.
A) Yes—70%
B) No—30%
A liberal attitude.

33) The next time a ham operates from space, which band should he/she use?
A) 2 meters—12%
B) 220 MHz—4%
C) 450 MHz—36%
D) An even higher band—12%
E) Shouldn't bother to operate—36%
Says a lot about the state of 2 meters and amateur radio in general.

34) If, while tuning across a band, you heard a net called "Jammers International" in progress, would you:
A) Jam it—8%
B) Ignore it—13%
C) Complain to the FCC or some other organization—63%
D) Listen—15%
E) Join it—1%
A sensible attitude, I think.

35) If required, could you solidly copy CW at the speed at which you were licensed?
A) Yes—70%
B) No—30%
Yeah, sure.

36) If required, could you pass the FCC theory test for your license class?
A) Yes—72%
B) No—28%
Uh, huh.

37) Have you ever purposely operated in an amateur subband you weren't licensed to use?
A) Yes—10%
B) No—90%
Whew.

38) Do you think the ARRL affects amateur radio in a positive manner?
A) Yes—37%
B) No—63%
Those figures need some work.

39) Do you ever speak to foreign, non-English-speaking hams in their own language?
A) Always—2%
B) Sometimes—16%
C) I attempt it—25%
D) Rarely—5%
E) Never—52%
No major change from last time.

40) Do you feel yourself competent to replace the finals in a tube-type rig?
A) Yes—90%
B) No—10%
You pull on the glass part.

41) Do you feel yourself competent to replace the finals in a transistor-type rig?
A) Yes—74%
B) No—26%
A handy talent, to be sure.

42) Do you solder together your own coax connectors?
A) Yes—95%
B) No—5%
Good.

43) Is your antenna system mounted on your house or a tower?
A) House—93%
B) Tower—7%
I don't have room for a tower, either.

44) Have you ever designed your own antenna?
A) Yes—4%
B) No—96%
The gremlins crept into this question. I don't know who was responsible for leaving it off the response form, but whoever you are, I sentence thee to two-dozen lashes with a section of RG-58/U (better

make that RG-8/U). By the way, I've never designed a skyhook, either.

45) What do you think of contesting?
A) Great—10%
B) Good—25%
C) Okay—11%
D) Don't like it—23%
E) Despise it—31%
No significant change here.

46) What do you think of DXing?
A) Great—35%
B) Good—27%
C) Okay—12%
D) Don't like it—12%
E) Despise it—14%
Or here.

47) What do you think of repeaters?
A) Great—35%
B) Good—10%
C) Okay—35%
D) Don't like them—12%
E) Despise them—8%
Or here.

48) What do you think of traffic handling?
A) Great—10%
B) Good—29%
C) Okay—29%
D) Don't like it—11%
E) Despise it—21%
Or here, either (ho-hum).

49) If you heard an emergency net in progress, would you immediately join in and offer your services?
A) Yes—64%
B) No—36%
I say, stay away until you're called for.

50) Should all hams be required to join some type of national amateur-radio organization?
A) Yes—11%
B) No—89%
The independent spirit lives.

SELECTED COMMENTS

I hope they don't get a minimum age requirement or I'll probably be off the air for a few years (age 14).—**KC0XK**

This is the first time I have participated in a survey like this. Tnx.—**K9QWJ**

Hey! Why no provocative questions this year? Re question 23, there should be a maximum age—**AF2M**

Most CW operators on a DXpedition operate at a high rate of speed—35 to 40 wpm. I think this adds to the confusion. People "think" they worked him instead of knowing they did. It also makes it hard for the 20-wpm-and-under people to work the station.—**N4TL**

I'm sorry to see very few questions about the ARRL... More attention should be given [by the League] to young people; less money wasted by the big shots in Newington and less control of power by the old, biased Board of Directors.—**N4CXF**

At age 74 I am now an SWL of ham bands. Do have gear for two complete stations, but the personal thrill is gone.—**W6KBH**

Pikesville MD 21208

You know, sometimes the weather can be vicious! I mean, here I am in May, writing a column for August, and the Baltimore weather is as hot and muggy as any summer day. Oh well, my sinuses do not appreciate that!

I bring this up to tell the tale of how I escaped the heat by retreating to my basement, an unfinished subterranean recess which is naturally cool and contains boxes and boxes of material yet unpacked from our move last year. In one of them I found a whole bunch of letters from some of you, many of which remain unanswered. I shall share some of them, along with some recent arrivals, with you all today.

An article in a recent issue of *Scatter*, the journal of the Southern Counties (CA) Amateur Teleprinter Society, raises an interesting point. With all of the discussion about video and computer RTTY setups, we tend to overlook the many amateurs who continue to use mechanical teleprinters. Years ago, we used to terminate each line with two carriage returns, one line feed, and two letters characters, i.e., CR-CR-LF-LTRS-LTRS. While this may be overkill and may double-space for the station that inserts a line feed for each carriage return, a truncated CR-LF-LTRS-LTRS would still be very appropriate and allow those with mechanical-type baskets the luxury of copying the beginning of each line.

Let's go a step further and look at the variety of ways in which RTTY stations can communicate, from direct to through a repeater. We recognize that transmission delays through a repeater may chop a second or two off the front of a transmission and that mechanical clutches may need a character or two to come up to speed. Further, garbage may have crept in and left the carriage in the middle of the current line. What is needed is a protocol to ensure that the beginning of each transmission is received and that each line is received as well.

One such procedure would be to activate the transmitter, then either pause with a blank carrier for a few seconds or send a timing signal composed of either BLANKS (Murray code 00000) or LETTERS (Murray code 11111). Follow this with one carriage return, one line feed, two LETTERS, and then send each line of the transmission. Follow each line with the same CR-LF-LTRS-LTRS sequence. When you are through, send another end-of-line sequence to place the printer on a blank line so that garbage will not cause the printer to overtype your just-sent data, and turn off the transmitter.

Now, moving right along, regards to Tom Clancy N8RC. Tom is living up in Frederick, Maryland, quite a ways from here, and is looking to return to RTTY after years away. Come on in, Tom, the techniques may have changed, but it's more fun than ever! Let me know how you do.

Theodore E. Deusner of Kennewick, Washington, asks about receivers for RTTY reception. One of the ones he asks about is the venerable Hammarlund HO-180. This receiver, or any other one which is stable enough to receive SSB, should be fine for RTTY. If the receiver has a bandpass which prevents generation of the "common" RTTY audio tones, in the 2000-Hz range, it is possible to use alternate tones that would still work but would fall within the "standard" SSB bandpass. Good luck with the efforts.

Another note here is from Bill Pascale W6JED of Oroville, California. Bill has been a fan of the column since his interest peaked on RTTY, and he states that he enjoys the column. So do I, Bill, and I especially enjoy hearing from you all; thanks for the letter.

A letter from Dick Chambers WA4GKR in Wilmington, North Carolina, asks a question that is on many an amateur's mind. He wants to know which features of modern RTTY terminals are desirable, and which of a series of named units is the "best" in several of these areas. Some of the features Dick mentions are the ability to send and receive CW, ASCII, and various speeds of Murray, as well as split screen, buffers, automatic screen formatting with word wrap and editing, and the like. Well, Dick, my first response is to state that RTTY is a mode that is, to me, as captivating running an old Teletype® Model 15 as it is with a video terminal. So, I am not really sure which of these, or other, features will be important to *you*! I would advise you to just try to get onto RTTY with as little outlay as possible, enjoy the mode for a while, and then upgrade your station with those features that you have heard about and seem important to you.

The problem with rating the various terminals, Dick, is that I have little more information than you do. Like you, I read the ads and the press releases published in the various journals. I have also written to most of the manufacturers for specific information and, almost without exception, have received little in the way of concrete information. If I have been given access to a piece of equipment, you can be sure I have written all I could find out about it while running it through its paces. But those events have been few and far between. Most manufacturers have not even supplied information over that in the ads; some have promised material and never come through. If I could build some sort of comparison, I would, but I hesitate to build it on only the claims gleaned from advertisements. Hope this helps.

Now, Edward Stetzer K2ZBA writes a note asking about one of the units I did review, the Microlog 6800. Edward, I had that unit up and operating through the courtesy of Microlog for about a week and was thoroughly impressed. I reviewed the terminal in the February and March, 1981, RTTY Loop columns in *73*. I am sending Edward some of that information; others who are interested are invited to look at those issues of the column. I have not had the opportunity to see any of the more recent stuff coming out of Microlog, but with the solid base of the original 6800, I feel sure they are moving onward and upward.

Years ago, I had an old tube-type, rack-mounted, and very heavy demodulator made by the Northern Radio Corporation. This came to mind with the receipt of a letter from Joe Sabo KB7NU of Bothell, Washington. Joe writes that he is the service manager at Northern Radio, in Redmond, Washington, manufacturers of marine SSB equipment. The Northern Radio company that manufactured the RTTY equipment, much of it for the military, was a different company. Nonetheless, Joe's company receives about five to ten calls a month asking for parts or service for that old, but venerable, equipment. Joe points out that the RTTY manufacturer Northern Radio was sold to RF Harris, who later sold the parts inventory to QEI. They may still have a limited supply of parts for old Northern RTTY equipment. You might address any questions to QEI, Inc., 60 Faden Road, Springfield, New Jersey 07804. Thanks for the information, Joe.

Jim Pruitt WA7DUY from Lewiston, Idaho, is another ham interested in putting his CoCo onto RTTY. Once again, Jim, the best source for CoCo software that I have seen is Clay Abrams, 1758 Comstock Lane, San Jose, California 95124. Clay features a variety of CoCo-compatible RTTY software and should have a disk version available soon. Right, Clay?

The third issue of basic RTTY tips is now available and may be obtained by sending $2.00 to me at the address at the top of this column. Of course, the first two issues remain available, and I shall be including a listing of what is available for those who missed previous issues. For those who came in late, much of this information was covered here in RTTY Loop during the first few years of the column and is being offered as a service to those newcomers who may have missed it.

Some hardware is on the books for next month—that and more, you never can tell, here in RTTY Loop.

HAM HELP

An American priest who has been a missionary in India for many decades wishes to set up a ham-radio station in a boys' orphanage. It would be used for educational purposes and so that he can contact his many benefactors in the United States, Canada, and England. Donations of working ham-radio equipment or donations of funds to purchase such equipment are being requested on his behalf. Please address:

Rev. Father A. Seeber S.D.B.
The Citadel
18 Landon's Rd
Madras 600 010
India

Wanted at a reasonable price: two i-f transformers for an R-392 receiver and the following tubes: twelve 6AJ5s, four 26A6s, two 26C6s, two 26D6s, and two 26A7s.

Johnny E. Carr WA4FCC
Route 2
Rockmart GA 30153

I am hoping to get in touch with someone regarding programming an EPROM for a paging encoder manufactured by Zetron in Bellevue, Washington.

HAM IN SPACE, TAKE 2

Tony England W0ORE may become the second astronaut to carry amateur radio into space. A joint AMSAT/ARRL proposal to NASA asks that Tony be allowed to operate on his upcoming 51F/Spacelab-2 mission, scheduled to fly during March of 1985. The proposal calls for more equipment to be carried aloft than was present on Owen Garriott W5LFL's ground-breaking flight, including automatic systems that will provide unattended operation.

UOSAT-2 RESPONDS

After more than ten weeks of silence, the sweet sound of telemetry greeted workers at the University of Surrey command station. After numerous attempts, the 2-meter telemetry beacon (145.825 MHz) sprang to life on May 7, providing valuable insight into the spacecraft's condition.

Thanks to *Amateur Satellite Report* for this month's news.

THE END OF THE IRC?

Is the International Reply Coupon on the way out? Dr. Vicente Tuason, the Director of Posts at Berne, Switzerland, recommends just that in his article in *Union Postale*. (*Union Postale* is the official publication of the Universal Postal Union, which administers the IRC.) Dr. Tuason cites the complexities of accounting for the International Reply Coupons (IRCs), and the increasing "abuses" in the form of currency speculation in IRCs.

The problem that Dr. Tuason wants to eliminate is exactly the feature of IRCs which makes them so useful in amateur radio and especially DX: IRCs are the best available approximation of a universally-accepted international currency. Since all IRCs are equivalent and can (supposedly) be redeemed in any country in the world, one can transfer funds from one country to another in the form of International Reply Coupons.

It seems that a few entrepreneurs are doing exactly that. In a country with rapid inflation, speculators are buying huge quantities of IRCs at a relatively low cost. They fly these IRCs to Switzerland, with its very stable currency, and, if their timing is right, can sell them to the Swiss Post Office for more than they originally paid! Switzerland, with its liberal banking laws and rock-steady currency, is taking the brunt of the speculating, and hence Dr. Tuason's recommendation that the International Reply Coupons be abolished.

Don't stay awake at night wondering how you're going to get that XU1SS card back without IRCs, however. Dr. Tuason's article recommending the abolition of the IRC appeared in April, 1957. The IRC has survived this and other challenges in the past 30 years, and most likely, will continue to do so for another 30.

Good thing, too, as the IRC plays a major role in DX and would be very difficult to replace. On the other hand, the IRC is one of the least understood aspects of the fine art of QSLing.

Universal Postal Union

To understand the IRC and its role, we must turn to one of the most basic tenets of international mails. When you buy a stamp for an overseas letter, *all* of the money for postage goes to the country sending, or originating, the letter. In this case, the United States Postal Service keeps the dough. The postal service in the destination country which still has to deliver the letter gets nothing. The various postal services argue that every letter will elicit a reply, so the recipient will purchase the stamp for the return letter, that country will get the funds, and the USPS delivers the letter to you for nothing.

This system requires no bookkeeping, leaves each country's postal service to set prices as it sees fit and eliminates delays while countries argue over who pays for what.

Such was the most fundamental concept of the Universal Postal Union (UPU), which was founded in 1874. (Incidentally, the UPU was founded some years after the International Telecommunications Union, and, in fact, was closely patterned after that organization.)

This system of letting each country keep its own international postal receipts worked fine except for one flaw, which was evident from the start. Some writers want to *prepay* the return postage to increase the chances of a reply. If the sender country keeps all the money for both directions, the postal service in the destination country gets nothing. But if you tried to send half of round-trip money to that country, you would have a bookkeeping nightmare.

So about 30 years after the UPU started, a solution to this dilemma was proposed: the International Reply Coupon. Approved by the 64 member countries in the UPU Congress of 1906, the IRC is now pushing 80 years old. And the concept of and need for the IRC remain unchanged.

The way the International Reply Coupon works (officially) is very simple. At any post office (well, almost any post office) you can purchase an International Reply Coupon for $0.65. You can send that IRC to someone in any member country of the Universal Postal Union, which includes just about every country in the world. The recipient can (supposedly) cash the IRC in at his post office for "one or more postal stamps representing the minimum postage for an unregistered letter sent by surface to a foreign country."

In other words, the IRC is good for stamps to mail one letter by surface transportation back to you. If you receive an IRC, you can cash it in at (almost) any post office for the postage stamps to send a surface letter overseas: say $0.30 for a letter to Europe, for example.

Postal authorities in the various countries may, at their option, exchange more than one IRC for airmail postage overseas. This gives rise to the lists in the *Radio Amateur Callbook* and other places for the number of IRCs needed to get an airmail letter back to you. This can range from as little as two IRCs to as many as six!

Note that the post office doesn't have to pay cash for the IRCs, only postage stamps. And the post office can require that you present the letter at the same time as the IRCs so that you can't even take the stamps and sell them for cash.

At least, that's the way the system is supposed to work. In practice, of course, this seldom happens. Instead, International Reply Coupons are a means of transferring small amounts of money from one country to another. IRCs are seldom cashed in because of the unfavorable exchange rate. (Who wants to lose half the money every time one exchanges an IRC for stamps?) The DXer hangs on to any IRCs he receives and uses them the next time he needs IRCs to get a card back, rather than running down to the post office and laying out $0.65 each for new IRCs.

After all, the IRCs are good "indefinitely," so why cash them in? Apparently other users than amateur radio DXers feel that way, as only about half of the IRCs issued each year are redeemed. And that includes the considerable number involved in currency speculation, a problem that continues 30 years after Dr. Tuason's article.

This "extra-postal" use of the International Reply Coupon will not be eliminated. In fact, one of the original justifications for the IRC, back in 1906, was just this service. Since small sums of money are frequently exchanged within a country in the form of postal stamps, the IRC could similarly supplement the international money-order system for very small amounts of money.

Since the IRC is supposed to be a limited form of international currency, it is not surprising that it plays that role in amateur radio. Indeed, most international amateur-radio debts can be settled in IRCs: return postage, award costs, etc. To keep the IRCs circulating, there is a "gray market" for the coupons. Most larger DX clubs and many active QSL managers and DXers collect hundreds and thousands of IRCs as they pour in from QSL-seekers. These IRCs are frequently sold for less than face value but more than their value at the post office. Typical for IRCs in bulk today would be around $0.40 to .45 each (watch the DX Bulletins for even better values, as big DXpeditions unload thousands of IRCs).

The resale market in IRCs benefits both buyer and seller. The purchaser saves considerable funds on the exchange, as opposed to buying new IRCs at the post office. The seller gets more money than the post office will give him, and this money is in the form of cash without restrictions. This exchange can be so advantageous that an active DX station, receiving lots of IRCs, can finance his entire QSL operation off the "profits." For example, VP2ML hasn't had to chip in a dime for QSL printing or postage in five years.

This particular "extra-postal" use of the IRC is so well accepted in amateur radio that even valueless IRCs are accepted and exchanged among amateurs. I still receive considerable numbers of "old" (and now worthless, at least at the post office) forms of IRCs.

"Planned Obsolescence"

"What?" I hear you say. "IRCs are good 'indefinitely'!" Indeed, UPU regulations state that the IRCs have no expiration date. In the fine print in the regulations, however, one finds the kicker: Only those IRCs whose texts agree with the official text have exchange value. Those with other wording cannot be exchanged at the post office. And the UPU changes the wording on the IRCs every few years! So despite the "indefinite" lifetime of the IRC, they do lose their official value occasionally.

The present IRC is version 15 and has been in circulation (with minor changes) since 1974 (see Fig. 1). The previous version (see Fig. 2) circulated between 1964 and 1974 and has not been accepted by the post office since 1979. Going still further back, we find an earlier version which circulated, with frequent minor changes, between 1929 and 1964 (see Fig. 3). This style was selected in a design competition in 1929 to replace the original IRC from 1906 (see Fig. 4).

I've never received one of the 1906 version, but I have a handful of the 1929-design IRCs, all received long after their "expiration" date. Since the IRC is seldom cashed in the post office, the official expiration of the IRC is not that important to the radio amateur. Since he is not going to cash it in but rather sell it to another amateur, or use it for an amateur-radio purchase, the official value of the IRC loses significance. As long as it is accepted by the amateur community, the IRC retains value.

Universal?

Another anomaly in the amateur-radio

UNION POSTALE UNIVERSELLE
COUPON-REPONSE INTERNATIONAL

Fig. 2. This type of IRC circulated until 1974 and has been obsolete since 1979. However, many still circulate through the amateur-radio community.

Fig. 3. Pre-1964 IRCs looked like this sample. A few of these still travel from amateur to amateur although they have had no official value for 20 years.

Fig. 4. A copy of the first version of the IRC, from 1906. The form and concept of the IRC have changed little in 80 years.

use of the IRC is in the Soviet-bloc countries. DXers frequently hear that IRCs are "not accepted" in Soviet countries, even though these countries are members of the Union. According to the Universal Postal Union, a country may decline to *sell* IRCs but is required to *exchange* them. However, the UPU has little enforcement power, and the Union has survived as long as it has by staying out of politics. So, many Soviet countries refuse to accept IRCs (at least at most local postal offices). Nevertheless, amateurs in these countries can and do use IRCs as international currency.

The "universality" of the IRC is not the only aspect of these coupons that local postal officials ignore. Many of the smaller post offices in this country do not stock IRCs, and the postmaster may never have heard of them. Even at larger post offices where they know what an IRC is, one can buy invalid IRCs.

Officially, the IRC must be of the current form, with the continuous UPU watermark. (Hold your IRC up to the light to see the watermark.) The current version of the IRC has the official text in seven languages: French, German, English, Arabic, Chinese, Spanish, and Russian. Each IRC must be stamped with the country of sale on the *left* side, as shown in Fig. 1. Unstamped IRCs or those stamped on the right are no good, and the post office can refuse to accept them (see Fig. 5).

Fortunately, enough postmasters are sufficiently ignorant of the rules to take enough bad IRCs in exchange for stamps to make up for the postmasters who issue bad ones. However, to be sure you're getting your money's worth, make certain the IRCs are properly stamped.

All IRCs are basically identical, as they are still printed by the same firm in Switzerland. Individual countries may ask to have a sales denomination printed in the center, as shown in Fig. 1. Otherwise, the center might be blank. The IRC is stamped on the right when it is cashed in to the post office. Used IRCs are destroyed after a complex accounting system balances purchases and sales between the member countries of the UPU.

Meanwhile, international speculation in IRCs continues. One needs only to glance down the list of sales and exchanges of IRCs to see the problem countries. Most countries have about the same number of sales and exchanges of IRCs. For every one sold, one is cashed in. A few countries stand out with enormous sales and few redemptions—especially the US and Japan. This is to be expected, of course, as the more affluent and more internationally-oriented countries buy and send out the most IRCs (especially hams!).

But countries such as Algeria, Ivory Coast, India, Morocco, and Libya sell hundreds of thousands of IRCs; these countries accounted for close to 20% of all IRC sales in 1981-2, but total redemptions were less than 1% of the biennial accounting! Why? Here is where speculators take advantage of the difference in exchange rate.

Fig. 5. An invalid IRC: it was stamped on the wrong side by the issuing USPS employee.

They fly their thousands of IRCs elsewhere, say, France, making a reasonable profit on the transaction. Since the profit on each IRC is small, these operators must deal with huge quantities of the coupons.

Most countries have established internal systems to eliminate this speculation. A loophole in the UPU regulations permits any member country to limit the sale of IRCs. Most countries simply won't sell you 100,000 IRCs at a crack! So the speculators need a sympathetic postal administration in the country of purchase.

Fortunately, this limits the abuse of the IRC system. Dr. Tuason's concerns notwithstanding, the IRC looks as if it will be around for another 75+ years, providing DXers with a much-needed international exchange medium.

(Special thanks to L. Rubens of the International Bureau of the Universal Postal Union for his invaluable assistance in preparing this column.)

PUBLIC DISSERVICE

Not too long ago I was in Carnegie Hall to see Peter Schickele and his orchestra, "The New York Pick-Up Ensemble." I had purchased the tickets at the last minute and had to choose among seats in the balcony, where the view leaves something to be desired.

Just as the performance was about to start, I was shocked to hear the loud high-pitched beeps of a 2-meter repeater's IDer. I looked around to see where this wretched noise was coming from and was able to locate its source! It came from a hand-held radio clipped to the belt of the gentleman seated behind me.

"Please turn your CB radio off," I said to him, in as nice a tone as I could muster. I carefully worded this statement, calling his 2-meter radio a CB, to infuriate him, which it did.

I was not, however, expecting the lecture that followed. He told me that he was performing a public service by providing a medium for emergency communication, carefully wording his statement so as to make one think that he was an undercover peace officer. I informed him that I had stopped "playing policeman" well before I entered kindergarten, and perhaps it was time for him to do the same, especially at his advanced age.

After his radio blared off about three more times, the usher came along and ordered him to turn the radio off or leave. He chose the option of leaving, and the remainder of the audience was able to enjoy the show without the nuisance of some misguided ham performing a "public service."

What reminded me of this story was that recently I was asked to operate a "specialized-mode" station for a local radio club during Field Day. I had to decline the invitation because I had tickets to see the comedian Pee Wee Herman at Carnegie Hall that same weekend. One has to keep one's priorities straight. I am only hoping that, because of Field Day, there will be less of a chance of my encountering another ill-mannered amateur-radio operator.

COMPUTER INTERFACING

Last month we examined one implementation of "memory-mapped" I/O control. Now we will examine another method, employed in the Atari and VIC computers as well as many others.

There are a number of integrated circuits known as input/output chips, or support chips, that are designed to work in conjunction with the 6502 microprocessor. (The 6502 is the microprocessor that both the Atari and VIC computers use.) These chips simplify I/O interfacing and eliminate the confusing conventions that other manufacturers, such as Apple, chose to employ.

The device we will look at is the 6520 peripheral interface adapter, or PIA. This circuit incorporates the circuitry for two I/O ports, each 8 bits wide. For each port there is a "data register" that contains the incoming or outgoing data and a "direction register" that controls whether corresponding signal lines are inputs or outputs. A zero is used to represent an input line and one is used to represent (have you guessed yet?) an output line. The programmer can control which lines are to be used for input or output simply by placing the proper combina-

tions of zeroes and ones in the direction register. Data are then read by examining the data register and are sent to another device by writing to the data register. It is really a fairly simple procedure. The 6520 PIA chip also contains a control register that contains various status signals needed for handshaking, and other bits to control the internal logic configuration.

On the Atari 400 and 800 computers, the data lines from the PIA chip are presented to the outside world via the four "Player Ports" on the front panel. See Fig. 1 for a pinout diagram of each of these ports. Commodore's VIC computers have a similar arrangement. Consult the *VIC Reference Manual* for complete details.

As the 6502 microprocessor has no specific input and output commands in its instruction set, all I/O is "memory mapped," that is, certain memory addresses are set aside for I/O use. If a PIA chip is used in conjunction with a 6502 to control I/O, it too must occupy memory addresses. The 6520 PIA requires four memory addresses; the exact locations of these depend on how the computer system was designed. In the Atari computers, the 6520 PIA is located at memory locations 54016 to 54019 inclusive (hex locations D300 to D303).

Internally, the PIA has six registers: two data registers, two direction registers, and two control registers. Because the PIA uses only four memory locations, it is necessary to have one extra bit to address the proper register. Bit 2 of the control registers serves this purpose. If this bit contains a 0, then the corresponding register is a data register. If the bit is a 1, then the corresponding register is a peripheral register.

Programming the PIA chip is often complicated because the computer uses this chip for its own internal purposes; reconfiguring it may cause the computer to do strange things (all will clear up when the computer is reset, or powered off and on). For example, Atari uses the PIA to control the joystick and stick triggers, the cassette recorder motor (on or off), and whether or not the voice channel of the cassette recorder is sent to the television set. The ability to control a cassette recorder makes it possible to have computer-controlled instructional material supplemented with recorded voice or music. Commands to control a cassette recorder are as follows:

POKE 54018,60 Turn cassette motor off
POKE 54018,52 Turn cassette motor on

The music, voice, Morse code, noise, or any material you have recorded on tape will play through the television set speaker. This technique might be used for a Morse-code or radio-theory computer-assisted learning program.

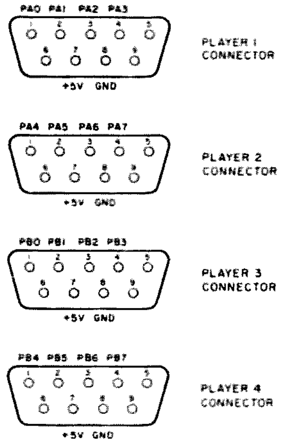

Fig. 1. The four Atari player connectors and the pins that correspond to PIA 6520 connections. The PAn series stands for port A, and the PBn series is for port B. Unmarked connections are used for paddle and stick trigger connections, and are not connected to the PIA chip.

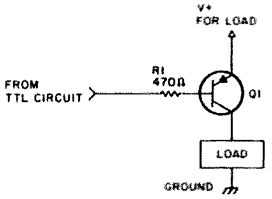

Fig. 2. Connecting a device to a TTL circuit using a PNP transistor.

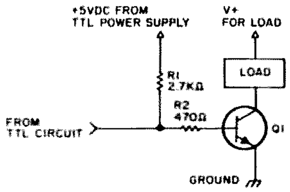

Fig. 3. Connecting a device to a TTL circuit using an NPN transistor.

Location 54018 is the Port A control location for the Atari's PIA. The POKE commands specified above change bit 3 of this register, which corresponds to control line #2, which is used to switch the recorder's power on or off.

This brief introduction to the 6520 PIA was meant to explain how memory-mapped I/O is aided with peripheral control chips. For a complete guide to configuring the 6520, I recommend the book, ***6502 Assembly Language Programming***, by Lance Leventhal (Osborne/McGraw Hill, 1979). Mr. Leventhal explains clearly the internal structure of the chip and provides numerous programming examples of real-life interface problems.

CONNECTING TTL TO THE OUTSIDE WORLD

The output of a TTL chip (such as the 6520 PIA) cannot be connected directly to another device; it simply doesn't have the current-carrying abilities. However, small loads can be controlled with the aid of a PNP or NPN transistor. Choose a transistor with enough current-carrying capability to drive your load. For controlling very large loads, it is recommended that you use either a transistor or an optoisolator. When using a relay, remember to connect a diode in parallel with the relay coil to prevent voltage spikes from ruining the transistor.

Figs. 2 and 3 contain the circuit diagrams for using a PNP and an NPN transistor, respectively. Notice that when using an NPN transistor, a "pull-up" connection is needed. This is because the TTL output must be provided with a current source in order to function correctly.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

THE WILDBUNCH 160 SSB CONTEST
Starts: 0000 GMT August 4
Ends: 2359 GMT August 5

This contest is for single operators only.

EXCHANGE:

RST and state, province, or country. Charter members must also give their membership number with the exchange.

SCORING:

Count 10 points per QSO and multiply by the total number of states, countries, and VE provinces. Work any charter member of the Wildbunch for a special multiplier of 1 point each. Work 15 charter members and get a special bonus of 20 points. Work the VE7WCB club station and add 10 points.

AWARDS:

Plaque to the winner and certificates to winners in each state, country, and VE province. Special certificate for working all 30 charter members.

ENTRIES:

Deadline for logs is September 6th, with entries addressed to: R. J. Koziomkowski KA1SR, 5 Watson Drive, Portsmouth RI 02871. To become a member of the 160-meter Wildbunch between June 1st and September 1st, US stations work 10 charter members, DX work 5. From September 1st to June 1st, double the number of QSOs required to 20 and 10. Send log info and US$2.00 for membership certificate and Wildbunch number to Bob LeBlanc KA1FDS, Unity Road, Benton, RFD 1, Box 800, Clinton ME 04927.

ILLINOIS QSO PARTY
Starts: 1700 GMT August 5
Ends: 0500 GMT August 6

Sponsored by RAMS, the Radio Amateur Megacycle Society. Use all bands, CW and phone. The same station may be worked on each band and mode. No repeater contacts are allowed.

EXCHANGE:

RS(T) and state, province, country, or Illinois county.

FREQUENCIES:

Any frequency, but look for most activity; about 40 kHz from low end on CW, and about 3890, 7230, 14280, 21375, and 28675 on phone.

SCORING:

One QSO point per contact or two points if the other station is a Novice or Technician in a Novice band. Illinois stations multiply QSO point total by the total number of states (50 max), VE/VO call areas (10 max), and no more than 5 non-W/K/VE/VO DX countries worked for a maximum of 65 multipliers. Additional DX contacts count for QSO points but not for additional multipliers. Illinois portables or mobiles away from normal QTH may add 200 to final score for each county of operation from which 10 or more contacts were made.

Non-Illinois stations multiply QSO points by the number of Illinois counties worked. Only Illinois stations may be counted for QSO points. Non-Illinois stations may also take extra bonus multipliers for each group of 8 QSOs with the same county.

AWARDS:

Certificates to the top 3 Illinois scorers in Single op, Multi-op, portable out-of-home-county, mobile, Novice, and CW Technician categories. For out-of-staters, awards go to top scorers in similar categories in each state, province, or country

NEWSLETTER OF THE MONTH

This month the laurels go to Editor Al Berg WB7SIC and *OTVARC*, journal of the Oregon Tualatin Valley ARC. Al tries very hard to include items of interest for everyone—a tough job in a club with 230+ members! The result is a collection of news and views presented in a friendly, easygoing style with eye-catching graphics that grab a reader's attention.

OTVARC is obviously a dynamic group of people who thrive on a steady diet of ham radio, social events, and public service. Congratulations to President Dave Parker W7LJN, Vice-President John Haide WA7CZA, and their fellow OTVARCs for doing it better than anyone else.

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

RESULTS

1984 VIRGINIA QSO PARTY

Winners of major award plaques:
Virginia fixed station—WA4NTP (78,921), Virginia mobile station—WA4PGM/M (63,800), Virginia CW only—KØRI (42,028), Virginia QRP station—KW4I (13,608), Out-of-state station—NC2V (7,590).

State winners (24 states)

AL—WA4VEK	ID—KA7T	MI—W8WVU	OK—KJ9R
AZ—W7YS	IL—KY9F	MT—KA7PMU	PA—W3ZX
CA—W6NNY	LA—W5WG	NC—K4JEX	TX—W5PWG
CT—K1BV	MA—WA1REI	NJ—NC2V	WA—W7DRA
FL—WK4F	MD—K3LK	NM—AI9X	WV—W3IJT
IA—KØHQE	ME—KA1ZV	NV—KA7GXO	WY—NC7O

DX winners: Canada—VE3KK; Spain—EA2IA.

from which 2 valid entries are received. Please send in even low-scoring logs to help another meet the two-log rule. Decisions of the contest committee are final.

ENTRIES:

Logs must be legible and be submitted along with a summary sheet listing all claimed multipliers and calculations of score. Operator(s) name, address, call, and operation category must be typed or printed clearly. Include a business-size SASE for return of results.

Entries must be postmarked no later than September 1st and sent to RAMS/K9CJU, 3620 N. Oleander Avenue, Chicago IL 60634.

NEW JERSEY QSO PARTY
2000 GMT August 11 to 0700 GMT August 12
1300 GMT August 12 to 0200 GMT August 13

The Englewood ARA invites all amateurs worldwide to participate in the 25th annual New Jersey QSO Party. Phone and CW are considered the same contest. A station may be contacted once on each band; phone and CW are considered separate "bands" but CW contacts may not be made in phone-band segments. NJ stations may work other NJ stations.

EXCHANGE:

QSO number, RS(T), and ARRL section, country, or NJ county.

FREQUENCIES:

1810, 3535, 3900, 7035, 7135, 7235, 14035, 14280, 21100, 21355, 28100, 28610, 50-50.5, and 144-146. Suggest phone activity on the even hours; 15 meters on the odd hours (1500 to 2100 GMT); 160 meters at 0500 GMT.

SCORING:

Out-of-state stations multiply the number of complete contacts with NJ stations times the number of NJ counties worked (21 maximum). NJ stations count 1 point per W/K/VE/VO QSO and 3 points per DX QSO. Multiply total QSO points by the number of ARRL sections (including NNJ and SNJ—maximum 74). KP4, KH6, KL7, etc., count as 3-point DX contacts and as section multipliers.

AWARDS:

Certificates will be awarded to the first-place station in each NJ county, ARRL section, and country. In addition, a second-place certificate will be awarded when 4 or more logs are received. Novice, Technician, and mobile-operator certificates will also be awarded.

ENTRIES:

Logs must show date/time in GMT, band, and emission. Logs must be received not later than September 8th. The first contact for each claimed multiplier must be indicated and numbered and a check-list of contacts and multipliers should be included. Multi-operator stations should be noted and calls of participating operators listed. Logs and comments should be sent to Englewood Amateur Radio Association, Inc., PO Box 528, Englewood NJ 07631.

A #10 (business) size SASE should be included for results. Stations planning active participation in NJ are requested to advise the EARA by August 1st of their intentions so that they can plan for full coverage from all counties. Portable and mobile operation is encouraged.

SARTG WORLDWIDE RTTY CONTEST
Contest Periods:
0000 to 0800 GMT August 18
1600 to 2400 GMT August 18
0800 to 1600 GMT August 19

This is the 14th annual contest sponsored by the Scandinavian Amateur Radio Teletype Group (SARTG). Operating classes include (a) single operator, (b) multi-operator/single transmitter, and (c) SWL. Please note the logs from multi-operator stations must contain the names and callsigns of all operators involved. The same station may be worked once on each band for QSO and multiplier credits. Only 2-way RTTY QSOs will count.

EXCHANGE:

RST and QSO number.

SCORING:

QSOs with your own country count 5 points. Other countries in the same continent are 10 points. Other continents are 15 points. In USA, Canada, and Australia, each call district will be considered as a separate country. Use the DXCC list and the above-mentioned call areas for multipliers. Note that contacts with a station which would count as a multiplier must be found in at least 5 logs or a contest log must be received from the multiplier station in order to be valid. Final score is the sum of QSO points times the sum of the multipliers. SWLs use the same rules for scoring, but based on stations and messages copied.

AWARDS:

Top stations in each class, country, W/K, VE/VO, and VK call district if the number of QSOs is reasonable.

ENTRIES:

Logs must be received by October 10th and should contain: band, date/time in GMT, callsign, exchanges sent and received, points, multipliers, and final score. Use a separate sheet for each band and enclose a summary sheet showing the scoring, classification, callsign, name, and address. In the case of multi-operator stations, include the names and callsigns of all operators involved. Comments will be very much appreciated by the contest committee. Send logs to: SARTG Contest & Award Manager, C. J. Jensen OZ2CJ, PO Box 717, 8600 Silkeborg, Denmark.

OCCUPATION CONTEST
Starts: 1800 GMT August 25
Ends: 2400 GMT August 26

The Radio Association of Erie, Pennsylvania, is sponsoring its annual contest, open to all amateur radio operators.

EXCHANGE:

RS(T); occupation; and state, province, or country.

FREQUENCIES:

CW—40 kHz from the bottom of the ham bands; phone—3920, 7250, 14300, 21400, and 28600.

SCORING:

Score 3 points for each new occupation worked, one point for all similar occupations worked, and 2 points for all retirees worked. There are no multipliers.

ENTRIES:

Mailing deadline for logs is October 1st, and they are to be sent to Harry Arsenault K1PLR/3, 603 Powell Avenue, Erie PA 16505. Enclose an SASE for a copy of the results.

CORRECTIONS

Re: "Painless Op-Amp Filter Design," April, 1984: The article contains a major technical error. All claims with reference to the gain characteristics of the bi-quad filter should be ignored. The erroneous interpretation of data acquired from breadboard models of the bi-quad resulted from too literally interpreting sources that list the gain of the bi-quad filter as its Q. This is true only for the design center frequency for normalized models. Examination of the transfer function for the bi-quad shows a relatively flat gain even for wide-frequency-range filters, such as those shown in the original article. Greater ranges of gain may be expected for variable-Q models. The measured results for breadboard models are in close agreement with or greater than predictions from the transfer function. The remaining design techniques, especially for determining the tuning range, still apply. For variable-output-level filters, an output-leveling technique is useful in many applications. I sincerely regret the error and offer my thanks to Frank W. Heemstra for pointing it out.

Knoxville TN

REVIEW

AMTORSOFT FROM KANTRONICS

All the talk over the past year or so about AMTOR left me a little bewildered. I even did my homework and looked up several articles on the subject to see if I could teach my Commodore computers how to speak AMTOR. About all I accomplished was to get myself totally confused! Modes of transmission that I can't decode bug me until I understand them. AMTOR is no exception.

I was relieved when Kantronics agreed to let me take a look at their AMTORSOFT program. Finally, I would find out what all that "chirping" is about!

The AMTORSOFT package works in conjunction with your home computer and a terminal unit or computer interface. The particular package I reviewed was designed for the VIC-20 and the Kantronics Interface II.

Throwing caution to the wind, I did what any self-respecting amateur would do. I hooked up the interface, did a system call to activate the software, and threw the instruction book on the bench! *That* was not a good idea!

The Kantronics folks had enough insight to include not only a very thorough instruction manual for the software, but also an overview of AMTOR itself for the uninitiated like me. Unless you have actually seen AMTOR work, please read the book first.

My previous reading about AMTOR had taught me that there are two forms of transmission: Mode B (the broadcast mode) is the form developed for transmission of general-interest bulletins and such. In Mode B, the signal sounds very similar to ASCII transmissions. No chirping takes place. What I hadn't read was that other than for ARRL bulletins, almost no one ever uses it!

I mistakenly selected mode B from the software menu and was disappointed that I could never seem to make anything print. That was my first hint that I should read the instructions.

I finally figured out that I needed to be in the L or listener mode if I wanted to eavesdrop on AMTOR conversations. The AMTORSOFT package provides you with several software LEDs, as I choose to call them, to let you know when you are successfully locked to an AMTOR signal. These indicators are labeled L, V, X, and I. A solid block displayed below the L indicates that you are locked or in synch with an AMTOR signal. The battle is half won! The V indicates that you are receiving valid AMTOR characters. The block below the X only comes on when you are transmitting, and the I block flickers on from time to time to indicate that the station you are receiving is sending idle characters—something like RTTY diddle.

After some patience and learning the hard way that it may take ten or more seconds for even a properly-tuned signal to lock, I started seeing my first AMTOR copy.

For those of you totally unfamiliar with AMTOR (or who are like me and forget everything you read), suffice it to say that the transmissions occur in three-character blocks. If a block is received OK, the next three-character block is sent. If the receiving station doesn't acknowledge that a valid block has been received, then the transmitting station keeps sending it until it is acknowledged. With that in mind, consider what happens when you eavesdrop on a conversation.

Since you are not an active participant in the QSO, you have no way of telling the transmitting station whether you have received the information or not. This can result in some strange copy at your end. Let's say the transmitting station is sending: K9EI K9EI DE WB9YJC WB9YJC. Suppose that just as the transmission begins, a bad static crash wipes out the first three characters for the intended station, but doesn't affect your reception. If it takes three tries before the intended station acknowledges those first three characters, and then everything goes smoothly, your screen might look like this: K9EK9EK9EI K9EI DE WB9YJC WB9YJC.

If during the transmission you receive invalid or no information, your screen will simply remain blank until the next valid set of characters is received.

The next problem I encountered was that of stations calling CQ. To put it simply, they don't! Not in the traditional way, at any rate.

Old-time RTTY people may be familiar with selcal or selective calling. On mechanical machines, it is possible to program an on/off sequence that will respond to a certain four-letter code. For general purposes, NNNN is frequently used. On AMTOR, a similar system is used. A station wishing to call CQ will continually transmit a four-letter block which sometimes consists of CQCQ or perhaps a shortened form of the originating station's callsign. For example, I might use KKEI or WYJC. A receiving station can lock to this selcal and respond only when this particular code is seen. The AMTORSOFT package will display this selcal for you so that if you desire, you can lock to the transmitting station. Entering a null character group will lock to any received selcal.

In fairness, I must say that on my second day of operation, I did find that some stations use the B mode and actually do send CQ, but the majority simply start up with the CQCQ selcal. In such a case, the locked and valid indicators will come on, but your screen will print nothing. A word to those operators calling CQ in this manner (who I heard go on for 30 minutes or more without ever sending an ID). You better watch out. Though CW ID is no longer required, you do have to identify, and your four-character selcal won't meet the requirement.

Actual two-way QSOs with AMTORSOFT can be a joy once the initial contact is established. Due to requests for repeats on character groups, a normal AMTOR QSO speeds along at about the same rate as 60-wpm RTTY. If a lot of repeats are necessary, the QSO can go slowly, but quite accurately.

Something that must be contemplated when setting up your station for AMTOR is the switching time of your transceiver between transmit and receive. Most modern transceivers will work well, but if you are not sure, check before you buy.

Another problem I had not considered is that most power amplifiers cannot respond quickly enough to meet the AMTOR timing requirements. The instructions with AMTORSOFT state boldly that operation with a linear should not be attempted.

That certainly explains that while I could find some very strong RTTY signals on 20 meters, all of the AMTOR transmissions were down 12 dB or more. Everyone is running in the 50-Watt or so range!

A beautiful example of how effective AMTOR can be is a QSO I monitored between an east-coast station and a maritime mobile station off the coast of South America. Both were using the AMTORSOFT package. The QSO began with both stations at about 50 Watts. Both stations kept reducing power until each was running under five Watts. From my listening, it was apparent that the QSO was solid with a minimum of repeats. Anybody want to try for an AMTOR QSO using an HW-8?

I finally did get to copy the W1AW bulletins on mode B. Of course there is no allowance for feedback to the transmitting station, so each group of characters is sent twice. The software determines whether one of the character blocks received is valid and prints only the valid one. If invalid data is received both times, garbage is not printed—rather blank spaces are sent to the screen or printer. During an approaching thunderstorm, my copy of the bulletins was nearly letter perfect, with only three blank spots during the whole 30-minute transmission. The Teletype* bulletins at the same time were a disaster.

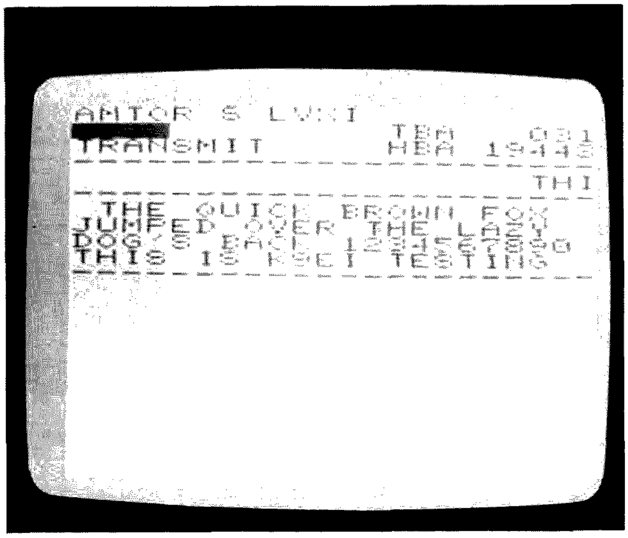
AMTORSOFT has all of the text-holding and editing features of HAMTEXT, the CW/RTTY/ASCII package available from Kantronics. Those features have been detailed in several reviews elsewhere, so I won't go into them here. The software contains the equivalent of a mini word processor and will allow you to store received messages in a buffer, save them to disk or to tape, edit, and resend them.

The AMTORSOFT package receives and sends AMTOR only, though Kantronics has a special version of HAMTEXT with AMTOR that combines both packages.

It seems to me that AMTOR is a godsend for the serious QRP enthusiast who is interested in doing RTTY-type things. AMTORSOFT is just another in a string of excellent software packages from Kantronics, priced at $89.95 list. It is highly recommended.

For further details, contact *Kantronics, 1202 East 23rd Street, Lawrence KS 66044.*

Jim Grubbs K9EI
Springfield IL 62708



The AMTORSOFT screen as generated by a VIC-20. Note in particular the dark rectangle in the upper left hand corner for displaying selcal. The software LEDs (LVXI) are located just above and to the right of the selcal block.

AEA MBATEXT SOFTWARE

The power of computer world processing has come to amateur radio! The AEA software packages for the VIC-20 and Commodore 64 computers offer a very versatile approach to several modes of amateur transmission.

Known as MBATEXT for Morse, Baudot, ASCII, these software packages transform your Commodore computer into a state-of-the-art communications terminal. There are so many features included in MBATEXT that it is difficult to find a starting point.

MBATEXT comes as a plug-in cartridge, much like the ones used for computer games. In order to access the program, a SYS (system) command is used. This allows you to call the program from your own Basic program. If, for example, you wish to use other than the default screen and text colors, you can write a brief program to set them to your own choices and then call MBATEXT.

Once you have entered the program, everything is menu-driven. You are presented with several choices from the main menu. As you make selections, you may encounter additional detailed menus at any time. Before concentrating on the operation of MBATEXT for transmission and reception, let's look at the common text-editing system.

Those of you familiar with regular word processing would expect a program to provide several different functions. First, you should be able to enter text on the screen and edit it to correct mistakes. Second, you should be able to save and load text files to and from cassette and disk. Finally, you should have the ability to print your file.

MBATEXT does all of this and much more! The text storage area has been designed with several different buffers. The size of these buffers is user-selectable up to the limit of available memory.

Ten buffers are available for programmed messages of your choice. These messages can be saved to tape or disk so that you can reload them when you first start the program. Incoming text, whether it be CW, RTTY, or ASCII can be saved in a receive buffer. It is possible to use the text editor to revise the text so that you can print or save just exactly the parts you want. Someone active in traffic handling can use this feature to great advantage, eliminating the need to manually transcribe and resend messages.

An audible "keyclick" is available if de-

sired to give you an indication that you actually have hit a key on the keyboard. Many operators find that this improves the accuracy of their typing.

Regardless of the mode you are operating, a transmit buffer is available so that you can compose an outgoing message while you are receiving messages. Even when you are on line and sending, you can type ahead of the text being sent. That's a real advantage when you are sending at slower CW speeds.

In the CW mode, you can select speeds up to 99 words per minute. It is really only necessary to set the transmitting speed; the receive speed will track the incoming signal automatically. It is really something to watch the speed indicator track the W1AW code-practice transmissions.

The screen is split into three sections: received text, transmit buffer, and a single line of outgoing text.

When MBATEXT is fed a signal from a compatible interface such as the AEA CP-1, it does an excellent job of receiving. CW transmission is very clean with perfect machine-generated code. At speeds between 5 and 14 words per minute, Farnsworth spacing is used. Individual characters are sent at about 15 words per minute with the spacing between characters increased to slow down the overall rate.

Several additional options are available. You have the choice of character or word mode on transmit. By selecting the word mode, transmission is held up until a space is encountered, and then the whole word is sent. That's particularly helpful for two-finger typists who make a lot of mistakes. Your errors can be corrected before they are sent!

You also have the option of selecting the break-in mode. The program automatically toggles between send and receive. What you lose is the use of the transmit holding buffer.

A Morse-code fill option can be selected. It is the Morse-code equivalent of RTTY diddle (sending null characters). If selected, the program will automatically send BT while you try to think of something to say. I didn't find that option very worthwhile.

Most of the features for RTTY and ASCII are similar since they are similar modes of transmission. Standard RTTY speeds of 60, 67, 75, 100, and 132 words per minute are included with ASCII speeds of 110 and 300 baud.

An unshift on space (USOS) option is available and can be handy when copying weak signals. One particularly nice touch is the RTTY "speed guess" mode. If you aren't sure at what speed the RTTY is being sent, this can be used to get you in the ball park. It isn't foolproof. Usually the average of several guesses gets you close.

AEA has included several keyboard overlays to help you keep track of what the function keys do, what you have stored in your message buffers, as well as where to find the special characters. It sure beats checking the instruction manual every time you forget.

MBATEXT will support printing to either a VIC-type printer (1525, 1528, MPS 801, etc.) or a Centronics-type parallel printer. A time-of-day clock at the top of the screen keeps you on schedule.

Operation with MBATEXT is a pleasure. Old-time RTTY tape splicers will find it to be the greatest thing since the spark gap.

AEA offers one-year support on the software that is even transferable should you decide to sell MBATEXT before the warranty is expired. MBATEXT is state-of-the-art software that would be a welcome addition in any hamshack.

For AMTOR enthusiasts, AEA offers MBATOR—which includes all the features of MBATEXT plus AMTOR, along with some additional MBA features.

TIMEX/SINCLAIR 1000: ASTRONOMY ON YOUR COMPUTER

This book (by Burgess and Burgess) might, on the surface, seem like a pretty strange topic for an amateur-radio publication. However, the computer programs presented in the 17 chapters of this little text have a lot to offer amateurs. But first things first. The book is published by Sybex, Inc., 2344 Sixth St., Berkeley CA 94710, and is 176 pages. (You can check on the current price with Sybex—it is modest.) Sybex offers a companion text that presents a collection of astronomical programs in Basic which are adaptable to a wide range of computers. It is *Celestial Basic*, by Eric Burgess (300 pages). The latter may interest hams with computers other than the Timex/Sinclair models.

Several chapters in the *Timex/Sinclair Astronomy* text are sure to interest amateurs. Chapter 2 presents a program that converts local time to sidereal or sidereal to local mean time. Chapter 7 has a program for the right ascension and declination of the moon. Chapter 8 computes the time of rising, transit, and setting of the moon. All of these programs are sure to interest moonbounce fans. A nice touch found in every program is the ability to set the latitude and longitude for your own QTH or for any other location on Earth. This would be a big help in coordinating schedules with other hams, since you can use the computer to search for common windows.

Chapter 15 has an interesting program for DX fans. It provides a method of computing the time of rising, transit, and setting of the sun. This will help in the identification of local conditions as well as those of a DX location on any selected date. Using the program, you can identify sunrise and sunset periods in the search for openings.

The rest of the text has a lot to offer for non-ham applications as well. There are programs to help identify constellations. One shows the location of the sun, moon, and planets at any time on any date. Another helps select the exposure for photographing astronomical objects. All in all, this is a very useful text.

The authors have done a very good job in presenting their programs in a clear and readable fashion. The output from sample runs is presented to clarify the goals of each program. Surprise—there is even an index—something that is left out of far too many low-cost computer books (and some no-so-low-cost books, too).

My overall evaluation of the text is highly complimentary. The book should appeal to hams with a general interest in relating astronomy to their ham activities. The text will be fascinating to those of us who find astronomy interesting in its own right. One caution—the programs are long and you must have at least 16K of memory to make them fit. There should be no problem in the conversion to other machines, for those interested.

Finally, there is one minor feature that I would like to have seen in the Sybex text, as well as in other books. I wish that the publishers had used a spiral binding. I have to hold one side down with my D-104 and the other with my Ten-Tec keyer. Otherwise I lose the page. Come on Sybex—let's be more considerate of the poor computer owner who has to hunt and peck as well as hold the book down with both elbows.

For more information, contact *Sybex, Inc., 2344 Sixth Street, Berkeley CA 94710.* Reader Service Number 482.

WHAT DO YOU THINK? ICOM 751 AND KENWOOD TR-2500

In December, 1983, you printed a very brief review on the Icom 751. I bought mine in March, 1984, after looking at all the competition. The review was very conservative at best. The radio is the greatest HF rig for the money that I have seen in years. By removing 1 wire (mute), it covers MARS and CAP use also. It took me two days of reading the manual to really become proficient with all its capabilities. I worked LU5AMF on 20 barefoot from my QTH in northern Japan—that's 17,000 km and pretty good considering my antenna is a HyGain 18AVT/WB vertical. Critical notes: S1 and S2 on the main board are for RTTY polarity and shift, respectively, but are inside the rig! I hope Icom will correct that and put them where they are readily available. I use the PS35 internal supply and 500-Hz FL-52 filter with it. It works great on RTTY also. If you need a good, small, neat HF radio for amateur, MARS, mobile, and RTTY, I think the 751 is just the rig.

In June, 1982, you reviewed the Kenwood TR-2500 and 3 months later I bought one. I have used mine in all kinds of weather (lots of snow and ice) and it works like a champ. It has been dropped on ice and concrete and it keeps right on working. I wrote to Kenwood and purchased the service manual at a reasonable price. To my surprise, the manual covers all the accessories, too. Critical comment: The speaker mike connector easily works loose and you have to keep pushing in the plug (which was not appreciated when I was hanging from a 60-ft. pole working on the repeater antenna). The TR-2500 will be a hard HT to beat for the money with the versatility that it has.

The above are the only two new radios that I have bought in over 17 years. I am very picky about what ham radios I buy. Now if I could only decide about what computer to buy.

OLYMPIC TRIUMPH

When the US Olympic Committee selected Olympia, Washington, to be the site of the US Olympic Women's Marathon Trials on May 12th, 1984, the local amateur radio club, the Olympia Amateur Radio Society (OARS), created a committee to interface with the task force running the marathon. As chairman of this committee, I found this assignment quite difficult for several reasons. Our job was to teach the marathon task force about amateur radio's utility in this kind of endeavor, find out what they would need, create a structure to provide the services required, and direct whatever communications effort was needed. The Women's Marathon Task Force was divided into about fifteen committees, and getting them to understand our unique communications capabilities was very difficult.

The task force's assessment was that there might be 100,000 people trying to view the event, and they did their planning on that basis. Olympia is a relatively small town and there was no way 100k people could see the finish or even see the last few miles of the race. The task force also did not know what events they would host for the runners prior to and after the race itself, what demands the media would make of them, how much support they could get from the community, how they would handle traffic...their assignment was incredible.

After a great deal of study, the marathon task force directors determined that their greatest need for our services would be during the race itelf, to provide to the race announcer and to the various media the position and time information on the progress of the race. (We might also have been assigned course security duty, but the US Olympic Committee was sending a 500-MHz Motorola system with 40 handhelds and a base station of the type to be used during the summer Olympics. This Motorola system and the State Patrol, Sheriff, and City Police systems would be the backbone of their security system.)

Initially, we planned to provide position and "splits" (time since the race began) for the race announcer and records people at each milepost of the 26.2-mile course. That would have meant 25 hams and timers on the course, plus net controls at the finish line. That was easy. However, a few weeks before the event we were asked if we could enlarge the system to also provide information from 1/2-mile points, from the the mid-race point, from the 1-mile-to-the-end point, and could we put someone in the pace car and on the ABC-TV truck? Also, could we put operators in the ABC-TV vans at the starting line (to remotely start 25 timers' watches at all of the 25 mile-markers), and in the Thurston County Communications Center (Medic-1, 911, etc.), and "there may be a few last-minute additions..."!

The OARS Committee designed the system we would use, taking input from everyone we could find. We would have two nets, one on two meters and one on 220, both on available county-wide-coverage repeaters, and we would alternate assignments. Thus, the one-milepost operator was on two meters, the two-milepost operator was on 220, etc. There were not enough operators in the Olympia area, for our operator needs were now around 60, with each operator asked to supply a timing helper.

We called the nearby clubs, the Mason County Amateur Radio Society and the Radio Club of Tacoma, Inc., and got the needed additional people. We tried to be fair. While none of the tasks was "dirty," some might be construed to be more "glamorous" than others, and we assigned the "glamorous" tasks evenly between the three clubs.

We found that the volume of data we would be collecting was too large to handle and compile using a paperwork system, so we developed a computer system to collate and distribute the data. This system evolved into a set of Radio Shack model 4s acting as dumb terminals driven by one model 4. We ended up with a 700-foot RS-232 run at 1200 baud, working perfectly, although we had full-duplex modems if we needed them.

The marathon task force wanted the positions and times on the first eight runners and selected "ones to watch." This meant about a dozen positions and times coming to the computer typist from the two nets. The net format was carefully designed to minimize repeating data and was a near-copy of the Navy MARS format. It demanded that after each position and time was reported, the net control acknowledged that piece of information. It worked perfectly.

ABC-TV was having a considerable impact on the information the marathon task force wanted us to provide and I was having some reservations about the legality of our plans. Would we be de facto news reporters? I called the Engineer-in-Charge of the Seattle FCC field office who referred the question to an attorney in the Personal Radio Section in Washington, D.C., and we had a 3-way conference call. The attorney was most helpful, observing that our prime objective was to provide the course announcer with information and that no remuneration was coming for our services. He contended that we were OK as long as no amateurs were placed on the air broadcasting race information directly. Our data was going into a computer which was creating a delay, albeit small, and we were "grinding" on the data, adding to the number we put in from the racer's shirt, her name, creating a split time and "elapsed-time-to-finish-at-this-pace" time, for display to the announcers. The two operators assigned the ABC-TV trailers were not to transmit information requests.

The weekend before the race we held a meeting for all the amateurs who would be participating. We handed out a course-operator location sheet, a map showing the precise location of each milepost, an instruction sheet, and a timer sheet with the net format. We went over the timing process and the net reporting process. Then each operator went to his/her location to make sure he/she knew where it was and checked the radios through the repeater at that location for any dead spots. We let the assembled multitude know of a possible major change: The FCC Special Temporary Authority (STA) requested by the marathon task force allowing use of the 500-MHz radios for the security team had been disapproved...it seemed that the system might cause interference with a low-power religious TV station 40 miles away! The marathon task force had Washington State Senator Slade Gorton trying to reverse the FCC and was scrambling for unused Department of Natural Resources (fire-fighting) radios as a backup in the meantime. But—if worse came to worst—one of our nets would become the security system! As it turned out, the security team borrowed enough DNR radios to do the job, but they did not get about 6 of them back. They were left on the sidewalk by the "security" people, or "lost..."

The amateur we had assigned the task of riding with the ABC-TV camera truck reported that rf from ABC-TV's own radio system and its CB radio, in the vicinity of the truck, would make the special gyro-stabilized camera mount go bonkers. The camera crew had been working two days to try to RFI-proof the mount, and when I went to check they looked a little bedraggled. We found that the 220 Icom 3AT didn't upset the mount, and the Icom 2AT did, only slightly, when on high power and right next to the mount. Eventually the camera crew managed to seal the mount from the RFI effects, and we mounted our mag-mounts on the other end of the truck and hoped for the best.

We borrowed a new 29-foot travel trailer from a local dealer and got it into position two days before the event, with 200-Amp service. We installed a copier borrowed from another dealer as a backup in case the computer system we'd developed didn't work. The copier was never turned on! The day before the event we installed the computers and radios and did a trial of the system the night before the event.

Race day came. As the position operators checked in, it became apparent that everyone had showed up—all 60 operators were in position! The town filled with spectators. Eight helicopters and several fixed-wing planes circled overhead at the start. The ham at the start transmitted the starting gun on both 2 and 220, and the 25 timing watches were started.

The runners set a blistering pace—five and half minutes a mile or better, and as they went by the first milepost they were reported to be chatting with each other... for them it was a Saturday 26.2-mile cakewalk! Our data began coming in and went into the computer and out to the course announcer 300 feet one way, to ABC-TV 700 feet another way, to KOMO-radio 700 feet another way, and to the press area near us (we were 140 feet from the finish line).

The race took two hours, thirty-one minutes, three seconds, for its winner, Joan Benoit, but much longer for its last-place runner, who was about halfway around as Joan finished. As runners dropped out, they came to our operators with requests for aid or for trainers to pick them up. These requests we relayed to the medical community or the racers' support areas.

After the race we held a brief evaluation meeting with the race directors—who were uniformly overjoyed with our operation. ABC-TV's comments were that they had never seen such a volume of data. While they had about 17 cameras and mostly operated real-time, they were impressed with our computers and with the smoothness of our system. As a result of this and other equally fine efforts by the 2800 volunteers from all over the state, we may get to do it again...in four years!

My suggestions for anyone planning such an event are that you try to conceive the eventual system months ahead. Sit around and brainstorm. Plan for a worst-case set of circumstances. If you do an event like this, create a notebook with a page for every milepost and position, where every change can be noted. Have permission from the repeater owners in writing, in advance of the operation, and have backups for everything, including people, equipment, and systems. Overdo it if possible. Give several people the task of documenting your efforts. Assign a cleanup committee to help tear down your system after it is over. Give credit to everyone—write letters of appreciation to anyone you borrow from on the most official stationary you can get! Take all credit and all criticism with a grain of salt. Have fun, and good luck!

AWARDS

MT. DAVIS DXPEDITION

The Somerset County Amateur Radio Club will sponsor its third annual DXpedition to the highest point in Pennsylvania, Mt. Davis, from August 4th at 1400 EDST to August 5th at 1400 EDST.

Frequencies are the upper 25 kHz on the General portion of the bands and CW in the Novice portion, with 80 meters being used after nightfall and 40 meters during the day. Each contact wishing to receive a beautiful certificate must send a 4½" x 9" or larger envelope. Send to: Box 488, Somerset PA 15501.

JERSEY SHORE ARS

The Jersey Shore Amateur Radio Society will operate KF2T at the Oyster Creek (NJ) Nuclear Generating Station between 1400Z Saturday, August 4, and 1800Z Sunday, August 5. Phone operations will be near 3930, 7270, 14270, 21270, and 28570 kHz. CW/Novice-Tech 30 kHz from lower band edges, VHF on 146.58. RTTY on 3640, 7080, and 14080. A special photo QSL is available for an SASE to JSARS, 819 17th Avenue, South Belmar NJ 07719.

THE BIRTHDAY BEAR

The Bemidji Amateur Radio Club, using the call KC0MJ, will be commemorating Smokey the Bear's birthday at the home of Paul Bunyan and Babe the Blue Ox on August 11th and 12th, from 1400Z to 2200Z. Operating frequencies will be 10 kHz up from the lower edge of the General-class phone bands on 20, 40, and 80 meters. To receive a special tri-color certificate, send an SASE, size 9" x 12", to Bemidji Amateur Radio Club, PO Box 524, Bemidji MN 56601.

PARAMUS NJ

The Bergen Amateur Radio Association

will operate K2TM from 1500Z to 2400Z August 18–19 to celebrate the club's 21st anniversary. Frequencies: 7.235, 14.275, 21.375, 28.675, 146.520. Novice: 7.125. Certificate for large SASE and QSL via K2UFM, 31 Forest Drive, Hillsdale NJ 07642.

WAG AWARD

The Worked All GARC or WAG award is given free to any amateur-radio operator who can submit written confirmation (QSL cards) of at least one two-way contact with each of twenty (20) or more members of the Gabilan Amateur Radio Club (GARC). The award consists of an attractive certificate suitable for framing and one bulb of fresh locally-grown garlic. Contacts may be made on any band or mode or combination of these.

The Gabilan Amateur Radio Club was founded in 1979 and draws its membership from the area surrounding Gilroy CA. This includes cities in the Santa Clara, San Benito, Santa Cruz, and Monterey County areas such as Salinas, Hollister, Morgan Hill, Castroville, and San Juan Bautista. The area lies on the fringe of Silicon Valley, south of the San Francisco Bay, but its primary industry is agriculture, including the growing and processing of garlic. The city of Gilroy sponsors an annual Garlic Festival, and this award is in keeping with that spirit.

Award submissions should be sent to the GARC Secretary, PO Box 2178, Gilroy CA 95021-2178. QSL cards will be returned only if accompanied by sufficient return postage. For a current roster of GARC members, send an SASE to the GARC Secretary at the address given above. To be valid for this award, stations must be members of GARC at the time of the contact, but need not be members at the time of the award submission.

ABC RADIO CLUB

The Amateurs for Better Communications (ABC) Radio Club of northern Illinois will operate KA9KOL on August 18–19, 1984, from 1700Z to 2300Z at the site of Lindenfest 84. Lindenhurst, a northern Illinois community and part of the gateway to the lakes region, will celebrate its second annual community festival. Look for KA9KOL on 7.240 to 7.245 and/or 14.280 to 14.285. QSL SASE to Terry Drews KA9KOL, 37328 N. Fairview W Lane, Lake Villa IL 60047.

SPACE DAY '84

The Cascades Amateur Radio Society (CARS), in conjunction with the Michigan Space Center in Jackson, Michigan, is offering a Space Day certificate to all stations who work WB8CSQ during Space Day activities. Look for WB8CSQ on 3.900, 7.235, 14.285, 21.360, and 28.510 starting at 0000 GMT August 18 through 1700 August 19. A one-dollar contribution is asked to cover cost of postage and materials. Mail your log information and $1.00 to CARS, Space Day '84, PO Box 512, Jackson MI 49204.

FOX RIVER RADIO LEAGUE

The Fox River Radio League will be operating a special-event station to celebrate the FRRL's 60th year of continuous operation. The FRRL will be operating from the Kane County Fairgrounds, St. Charles, Ilinois, on August 26, 1984, from 8 am until 4 pm (CDT) using the FRRL callsign W9CEQ. Suggested frequencies are 10 kHz up from the lower portions of the General-class phone bands on 40, 20, and 15 meters.

For a certificate or QSL, send your QSL and an SASE to: Fox River Radio League, PO Box 443, Aurora IL 60507.

NEW PRODUCTS

FIELD-STRENGTH PLUG-IN ELEMENT FROM BIRD ELECTRONIC CORPORATION

The latest addition to the assortment of plug-in elements for Bird Electronic Corporation directional wattmeters is an extremely sensitive relative field-strength element. Model 4030 expands the usefulness of Thruline™ wattmeters by helping optimize the radiated signal of any transmitter from 2 to 1000 MHz.

It is easy to increase the reach of business or personal transceivers and to extend the range of HTs by tuning, adjusting, and positioning antennas for maximum meter indication on the host wattmeter.

Model 4030 employs modern broadband circuitry instead of the highly reactive resonant networks of most field-strength meters. The element consists of a flexible receiving antenna, a single highpass network, and a variable-gain rf amplifier/detector. A battery-saving feature turns everything off when the element is removed from the wattmeter.

Typically full-scale deflection is obtained from a one-Watt CW source at 150 MHz through a quarter-wave antenna 8 feet distant. Dynamic range is at least 30 dB, and battery life is 100 hours or more.

For further information, contact *Bird Electronic Corporation, 30303 Aurora Road, Cleveland (Solon) OH 44139.* Reader Service number 477.

Model 4030 from Bird Electronic Corporation.

MCM ELECTRONICS 1984 CATALOG

MCM Electronics, Centerville, Ohio, a parts and accessories distributor to the electronics industry, has published their 1984 catalog.

The 120-page catalog contains more than 4,500 parts and accessories. Featured are over 500 new items, including an expanded line of computer parts, new styli, and video parts. Also included are a new line of magnetrons for microwave-oven repair, new test equipment such as the Tenma 20-MHz dual-trace oscilloscope, and a large selection of Japanese semiconductors.

For a free copy of the 1984 MCM Catalog, call toll free *(800)-543-4330* (in Ohio, call *(800)-762-4315*). For more information, contact *MCM Electronics, 858 E. Congress Park Dr., Centerville OH 45459; (513)-434-0031.* Reader Service number 480.

HD-8999 ULTRAPRO CW KEYBOARD

The HD-8999 UltraPro CW Keyboard, recently developed by Heath Company, is a third generation of code computers. A 64-character type-ahead buffer permits typing faster than the keyboard is sending. Ten variable-length buffers eliminate waste when storing text. Messages stored in the buffers can be compiled, corrected, or transmitted with no more than three keystrokes. A large, four-digit LED display indicates many functions: speed, spacing, weighting, serial number, remaining message-character space, input error, tune mode, sidetone on/off, keyclick, and individual buffer protection. An 8-segment bar graph indicates fullness of the type-ahead buffer. UltraPro parameters can be set from the keyboard, and battery backup of the CMOS memory retains buffer contents and last-used parameters should power fail or the keyboard be turned off. Three different four-level code-practice modes are built in, as are turn-on circuit diagnostics, a sidetone oscillator, and a speaker.

For more details on Heath's HD-8999 UltraPro CW Keyboard, send for the latest, free 104-page Heathkit Catalog. Write to *Heath Company, Dept. 150-355, Benton Harbor MI 49022.* In Canada, write to *Heath Company, 1020 Islington Avenue, Dept. 3100, Toronto, Ontario M8Z 5Z3.* Reader Service number 479.

TELEX/HY-GAIN ANNOUNCES HOT LINE

Minneapolis—Telex/Hy-Gain has installed a toll-free customer-service hot line for amateur-radio products. In the continental US, the number is (800)-328-5652. In Minnesota, the number to dial is (612)-887-5528. Calls will be accepted during normal business hours, Monday through Friday, 8:00 am to 5:00 pm, central time.

The company stated that the toll-free number is good only for calls concerning amateur-radio products. The purpose of the service is to assist amateurs with product selections and to help answer

The Heath HD-8999 UltraPro CW Keyboard.

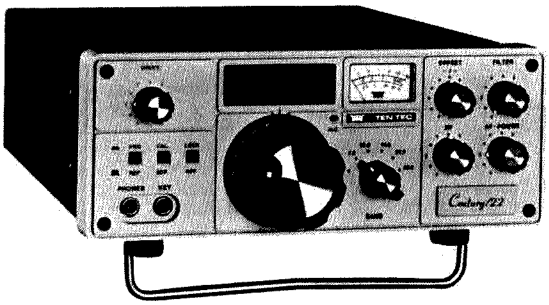
questions about applications or installations. The toll-free service is effective immediately.

For more information, contact *Telex Communications, Inc., 9600 Aldrich Ave. So., Minneapolis MN 55420; (612)-884-4051; telex, 29-7053.*

CENTURY/22 CW TRANSCEIVER

Ten-Tec has announced the Century/22, a 6-band CW transceiver. Premiered at Dayton, the new rig was scheduled for production in July. A worthy successor to the popular Century/21, the Century/22 fills the need for a reliable, low-power, no-frills yet effective HF CW transceiver.

For more information, contact *Ten-Tec, Inc., Highway 411 E., Sevierville TN 37862; (615)-453-7172.*



Ten-Tec's Century/22 CW transceiver.

DESIGN ELECTRONICS OHIO T/R SWITCH

Design Electronics Ohio has announced the introduction of the QSK 1500, an all-solid-state, American-made T/R switch which uses state-of-the-art high-power pin diodes for ultra-fast silent switching. The installation of the QSK 1500 between a QSK (full break-in) transceiver and any linear amplifier (including home-brew) allows full break-in QSK CW operation at the 1500-Watt power level. In addition, it also allows the operation of high-power AMTOR with any amplifier.

Since the QSK 1500 uses pin diodes instead of vacuum relays, its operation is totally silent. Installation requires no modifications to either your QSK transceiver or your amplifier. Because of its broadband design, the 1500 will operate from 1.8 MHz to 30 MHz without any additional switches or controls to adjust.

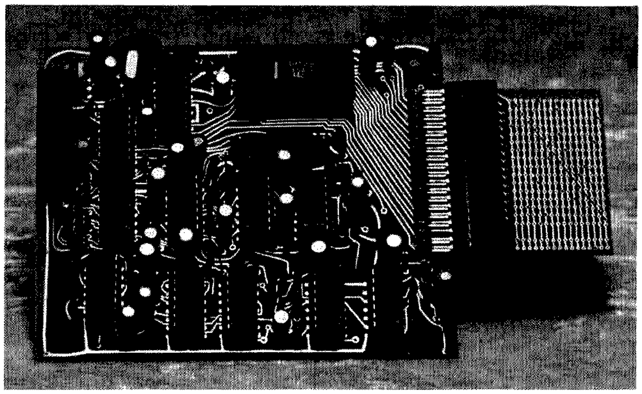
The external QSK T/R switch has virtually no insertion loss on receive and does not degrade the front-end performance of any transceiver. Guaranteed insertion loss is less than 0.6 dB and typical insertion loss is 0.25 dB.

The QSK 1500 includes at no extra cost a custom-designed power supply and control panel plus a receiver-line protection circuit which prevents damage to the front end of solid-state QSK transceivers due to the presence of high-power rf fields (such as multi-contest operations or nearby amateurs running high power).

Installation of the 1500 does not change the pattern or character of the transmitted waveform, nor does it produce any TVI or electronic garbage over the rest of the spectrum. It will not change the quality of the signal that your QSK transceiver and linear amplifier produce; it only switches your rf and does not alter it.

The QSK 1500 comes as a 2-unit set, color-coordinated to match most popular QSK transceivers. The two units furnished are the rf-switching unit which mounts out of sight behind your operating desk, and the power supply/control unit which is placed at your operating position. After installation, there is only one control associated with the 1500—the on/off switch.

For further information, contact *Design Electronics Ohio, 4925 South Hamilton Road, Groveport OH 43125, or call Ralph Rickett at (614)-866-4267.* Reader Service number 478.



The TTC300 touchtone remote-control board from Spectrum Communications Corp.

TTC300 TOUCHTONE™ REMOTE-CONTROL BOARD

The Spectrum Communications Corporation TTC300 is a new DTMF (touchtone) controller board which provides remote DTMF control of virtually any on/off function via a radio or any type of link with audio output (such as wire line or phone line). Typical applications include remote control of functions at a repeater site or any location with a radio line, and industrial controls at plants, pipelines, and construction sites, etc.

The controller includes the following features:

- new high-quality crystal-controlled decoder IC, with high immunity to falsing
- decodes all 16 digits
- 3 on/off functions per main card; expands to any number of functions with expansion cards
- field programmable via plug-in coded cards
- 3 latched on/off outputs, 4 pulsed outputs, or a combination thereof
- transistor switch outputs can directly trigger solid-state circuitry or relays, etc., for any type of control function
- can be interfaced to microprocessor controllers
- low-power-consumption CMOS technology; 5-V-dc input

For more information, contact *Spectrum Communications Corp., 1055 W. Germantown Pk., Norristown PA 19401-9616; (215)-631-1710; telex 846-211.* Reader Service number 481.

from page 60

laration of a Civil Emergency was imminent. At 0345 the CD warning siren system began sounding, but even this system was affected by flooding; only four of the seven sirens were operational. Added to that, only one of the three local radio stations remained on the air after the declaration of the emergency, the other two suffering water damage to studio transmitter cables.

The telephone call-out of AREC personnel to man CD HQ was thwarted because the flooding also had affected some of the telephone circuits. Only two operators were contacted by telephone. After the warning sirens had sounded, some AREC operators came up on the Invercargill 680 repeater and were directed to CD HQ for duties. Around 0415, several AREC operators had arrived at CD headquarters, and all reported having to take numerous detours to get to the headquarters building in the center of the city. Reports were being received through the 660 repeater of operators available but unable to cross the flood waters to get to the central city, so the communications center had to make the best use of the five operators available and hope that others would eventually somehow find a way to headquarters.

By around 0430, a small number of the CD HQ operations staff and emergency liaison officers had arrived and the operation of CD HQ was under way. A Civil Defense vehicle with a radio operator was dispatched to check the extent of the flooding, and information from this reconnaissance and the Emergency Service reports indicated a very serious flooding situation throughout the entire city area.

People evacuated so far were located and cared for in a welfare center opposite CD HQ, so no communications were required to that post. Regular situation reports were being received over the CD communications net on 149 MHz, and a steady flow of reports continued until about 1000 hours when it was reported that an evacuation was to take place in the suburban area of Grasmere. A radio link was set up with the welfare center at Collingwood School, where the evacuees from Grasmere would be taken.

While all this activity was continuing in Invercargill, the surrounding towns and areas in western Southland were experiencing severe flooding and residents were being evacuated. The Invercargill 680 repeater was used as a link between these areas and CD regional HQ, and the AREC communications vehicle was set up at CD HQ to provide ground-to-air communications for the two Air Force Iroquois helicopters being sent by the Air Force to participate in rescue operations with the two civilian helicopters already operating.

About 1400 hours, all hell broke loose as the flood banks on the Waihopai River broke and torrents of water engulfed the northern part of the city, the North Road industrial area, and the South Grasmere residential area. Within 30 minutes the water was six to eight feet deep, covering this large area of the city, and the Collingwood School welfare center was now cut off from the rest of the city.

Because of increased radio traffic, a spare portable VHF set was dispatched to the Collingwood center by 4WD vehicle, and a CD rescue squad was sent to assist in the Grasmere-Collingwood area. The 4WD vehicle and operator arrived at Collingwood almost an hour later, after detouring through Otatara, West Plains, and across country, after many extra miles, when in normal circumstances the journey would have only been about 15 minutes. Shortly after the arrival of the operator at Collingwood, the number of evacuees exceeded 300 and a decision was made to try to move these people to a welfare center established at the Hostel of the Boys High School. A convoy of Army trucks was to be used for this transport task, as the only suitable route was by North Road and this was covered by four to five feet of water.

A civilian radio operator and a VHF set were supplied to the Boys High School welfare center, as there was still a shortage of AREC operators at HQ and by now (1530 hours) the entire city was cut off by flood water from the rest of the country. Radio messages from the two welfare centers, from the rescue squads, and from a rescue jet boat kept the HQ operators extremely busy. Messages were being written on any piece of paper as the supply of message pads had run out and there was no time to go looking for more. About this time, the radio log became the communications center's record of many of the messages sent and received. All messages were unregistered because of the staff shortage, and as most messages required life-saving action, prompt handling was essential. For many of the messages, it was quicker for the operator to get the addressee of the message to the radio—then immediate action and reply followed, with only brief details being recorded in the log.

Around 1600 hours, the Iroquois helicopters arrived and became operational and joined the two commercial helicopters in rescues at Grasmere. Communication with these aircraft was on 119.1 MHz, and this operation fully occupied one HQ AREC operator.

At 1700 hours, floodwaters in the south of the city had dropped enough to allow some replacement AREC operators to report to HQ, and these operators were used to relieve some of the HQ operators who had been on duty for over 12 hours. The emergency operations continued into Friday night, it being necessary for an Iroquois rescue even at 0058 Saturday morning. The four aircraft returned to full air operations again at 0600 hours.

While the south city floodwaters were subsiding during Friday evening, those in the north and west were still rising. Evacuations continued in these areas throughout the night and into the early hours of Saturday morning. At 0600 hours, Saturday, 28 January, a volunteer Army-trained radio operator, now a civilian, arrived to operate the ground-to-air communications. He remained at this set until the next Tuesday, January 31, and did an excellent job. At 0700 hours, a request was received from the airport control tower to change frequency to 118.1 MHz, and as well as ground-to-air communications, CD HQ kept in touch with the airport as the water level rose there until eventually the tower operator had to be evacuated, the airport now being completely flooded.

Communications continued along these lines for the next few days, still with 24-hour operation. Operators were now more plentiful, with the return of AREC members from holiday, and a more civilized shift system could be introduced. Messages had now changed from rescue- to welfare-type communications, but the volume had reduced only slightly.

Tuesday, January 31, at 0800 hours, after 100 hours of continuous operation, the emergency was over and it seemed as though we could pack up, when the controller requested 10 hand-helds and operators to accompany the City Health, Electrical, and Building Inspection teams who were examining the evacuated homes to declare them fit for habitation again. These teams had a vital need for communications to coordinate their activities and to provide the information Center with details so the residents concerned could be kept informed. Most of the evacuated homes had been under six to eight feet of water and, to complicate matters, nearly all had been fouled by sewage due to the breakdown of the sewage system. Most could not be reoccupied until some remedial action was taken.

As many of the Invercargill operators were now back at their own work, it was difficult to see how this request could be filled, so an urgent call to Dunedin AREC for 10 operators with hand-helds and a portable repeater was made. The Dunedin team took over on Wednesday and continued until Sunday, February 4. A massive clean-up was scheduled in the Grassmere area on that Saturday, when 25 trucks, each with an operator with a handheld controlled by a coordinating center, were arranged. As well as the operators with the trucks, a further 11 operators were assisting with the inspection and welfare operations between the hours of 0800 and 1800, communications being on the two CD VHF frequencies and two 2m frequencies.

Operations were now scaling down until eventually, on Sunday, February 12, all AREC and CD equipment was dismantled, and any communications then necessary continued by telephone.

The size of the flooding disaster was enormous. The amount of damages was several million dollars, and at the peak of the emergency over 3000 people from about 1000 homes were evacuated and housed in welfare centers or with friends and/or relatives. It was to be some time before all those evacuated were able to return to their homes and return to a normal life again. Invercargill is a city of about 56,000 people, and from the statistics, about 5% of the population had to be evacuated from houses inundated by more than four feet of water during the height of the flooding. Other areas in the Southland district were also affected, and also most of the city of Invercargill.

The summary of the radio communications system indicated that it would be advantageous for all Civil Defense headquarters communications centers to have equipment available to operate on the amateur frequencies, so as to allow the large pool of hand-held amateur transceivers and portable equipment to be available for CD communications, since no local CD organization will ever have sufficient equipment of their own to cope with a similar extensive situation. The communications system must be portable and flexible to allow sets to be installed where you least expect it, and a total commitment to type-approved equipment on 148 to 150 MHz will not allow this to happen.

Once again, the Amateur Service has been able to put its expertise to good use in an emergency situation, and although Civil Defense has its own special frequencies, most of the operators in the CD communications system are ZL amateurs. But in this instance, also, because of the extensive nature of the disaster, additional radio assistance was made available through the Amateur Radio Emergency Corps, with additional operators, portable equipment, and the amateur-radio repeater systems within the area of the disaster.

ZL9—AUCKLAND AND CAMPBELL ISLANDS

Last month I told you a bit about the Kermadecs, ZL8. This month I shall try to provide you with a picture of the Campbell Islands.

The Auckland Islands are about 500 km south of the southernmost part of ZL and are uninhabited, except maybe for lots of penguins and seals. So there is not very much chance of a contact with the Auckland Islands unless some amateur visits the islands for some obscure reason. However, the Campbell Islands are a different kettle of fish. Campbell Island, situated 52° 33' S, 169° 8' E in the South Pacific Ocean, covers an area of 114 square km and is about 48 km in circumference. The island is semicircular, has good harbors, and is now a manned weather station, playing an important part in the forecasting of New Zealand weather.

Prior to this, it was used as a coastwatching station during World War II, and the history books tell us Campbell Island's first settlers arrived in the early 1800s. Activities on the island included sealing and whaling, and in later years a sheep station was established.

As a weather station, there normally are about 10 people there at any one time, and the normal stay is 12 months (from November to November). A typical island crew is an officer in charge, a cook, a mechanic, four Met personnel, and three technicians.

Besides three hourly weather observations and two radiosonde balloon flights each day, Department of Scientific and Industrial Research observations of a more technical nature are made. These consist of a close examination, at 15-minute intervals, of the ionosphere's layers, riometer recordings (relative ionospheric opacity receivers) observing ionospheric noise at 30 MHz, variations in the magnetic field (which is quite considerable at this latitude), and VLF recordings using a delta loop made for Otago University.

Auroral displays are quite common at Campbell, and a 16mm all-sky camera operates every night taking one exposure every five minutes to record the event, though on many nights an abundance of clouds makes it difficult even for an amateur photographer. Continuous seismological recordings also are made at Campbell.

The technicians process the magnetic and seismo records once each week, and the results are then sent by radiotelephone to Christchurch.

From time to time, amateur-radio operators are amongst the technicians who are down at Campbell Island for their year's term, the last one being John Holtum ZL3HI/A, a Grade II operator, who was active on 80-meter phone and CW as well as 2 meters. John was at Campbell during 1982/83.

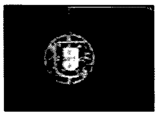
The International Commission of PRAA (Polish Radio Amateurs Association) has its hands full. The congress of the First Region of IARU took place in Sicily this year. Many documents and suggestions have been prepared for the Executive Committee of IARU, the Ministry of Communications, and Headquarters of PRAA. As delegates to the congress of IARU were appointed SP5LVV, SP5HS, SP5BFW, and SP6ARE. The chairman of the EMC team is to be SP9ZD. As a candidate for Executive Committee of the First Region of IARU, Wojciech Nietyksza SP5FM has been proposed. In connection with the World Year of Telecommunication, the State Radio Surveillance gave its consent to have 10 Polish radio stations under the WCY banner.

The following contests are included among "Intercontest KF 1984" in Poland this year:

- SP DX Contest (SSB)—April 7-8.
- WPX Contest (CW)—May 26-27.
- CQ MIR—May 8-9.
- All Asian Contest (SSB)—June 16-17.
- IARU Radiosport—July 14-15.
- WAE DX Contest (CW)—August 11-12.
- All Asian Contest (CW)—August 25-26.
- WAE DX Contest (SSB)—September 8-9.
- CQ WW DX Contest (SSB)—October 27-28.
- CQ WW DX Contest (CW)—November 24-25.

The President of PRAA, Prof. A. Zielinski, sent a telegram of condolence to the ARRL because of the death of the President of the ARRL, Vic Clark W4KFC, a well-known in Poland American sender.

Lately it was announced that District Verification Boards had brought 2,860 individual and 193 club licenses up to date by the end of November, 1983. This is not many in comparison with the about 12,000 Polish radio amateurs.



PORTUGAL

Luiz Miguel de Sousa CT4UE
PO Box 32
S. Joao do Estoril

We shouldn't have any doubts that *73* is a magazine read all over the world, according to the letters kindly sent to me in the past weeks by CT1AGC/Panama, CT1DN/CR9, DL2MCM, G4VUB, PT2ZAI (who came last March), PY4LF, N9DZO (who called me from REP Headquarters), W1BFA, W4DGA, KA1EWT, W1TIV, and others. For all of them, my sincere thanks.

IFACTA 84 PORTUGAL

Last March, on the 25th, for a period of one week, a very important meeting was held in the Estoril Sol Hotel (Estoril). Ernie Bracy W1BFA, who came for the conference, too, left us a report concerning that event, as follows.

Rede dos Emissores Portugueses (REP) was host amateur-radio station for the annual conference of the International Federation of Air Traffic Control Associations and took its place among others in welcoming the air-traffic-control people to Portugal. Other participants included the President of Portugal, the Minister of Social Equipment, the Mayor of Cascais, the General Tourist Office, and the public corporation, Aeroportos e Navagacao Aeria (ANA).

Each year W1BFA operates an amateur-radio station in conjunction with the conference. (Last year's operation was in Yugoslavia and the callsign was 4N0ATC-W1BFA/YU2).

Ernie arrived in Portugal on March 24th. It was a windy, showery day. However, amid high gusts of wind and downpours of rain, he and I installed a minibeam (HQ1) on a superstructure on the top of the Hotel Sol Estoril, the equivalent of 20 stories in the air. A top-floor room had been reserved, but at the last minute it became unavailable. On Sunday, the 25th, Ernie ran the cables down to the 12th floor and put the FT-902DM T/R loaned by REP on the air. It was just in time to make a few WPX Contest QSOs and check out the coverage.

Daily, during the conference, station CT1REP/W1BFA was utilized as the Net Control Station for the International Air-Traffic-Control Net which operates on 14.277 kHz 10:30-12:30 UTC. (Last year the net had 900 stations check in; it supports a regular membership of over 100 stations.) The net is made up of air-traffic controllers, pilots, aviation technicians of various categories, and aviation-interested people. Additional information can be obtained from W1BFA, net controller.

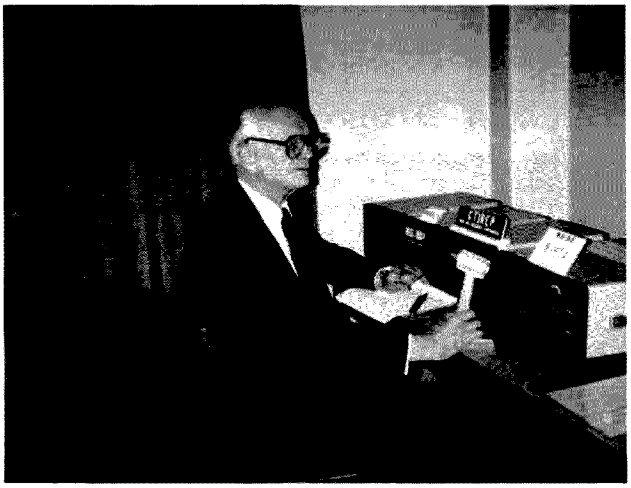
Contacts during the week were maintained with some 30 countries in spite of the poor propagation. The IFATCA Conference was attended by people from nearly 50 countries. In addition to W1BFA, EI4BK, a G operator, and TF3MXN were in attendance.

Ernie W1BFA expressed his warm, heartfelt appreciation to REP for the loan of the equipment and for giving permission for the operation in Portugal.

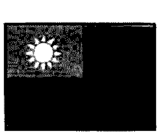
ELECTIONS IN REP

On the 31st of March, the annual General Assembly was held in Lisbon to approve the accounts and to elect a new board of directors for 1984/85. Due to the absence of candidate lists, the Assembly elected an administrative commission of 5 members who should prepare for new elections in a year's time. We are sure that the new members will continue the hard and exhaustive work that is involved in an association such as REP and all the important affairs, like reciprocal foreign licenses, info for new hams, QSL bureau, periodical information sheets, etc.

That's all from this sunny and warm country. *73* until next time.



W1BFA operating CT1REP from his Estoril hotel. (Photo by CT4UE)



TAIWAN

Tim Chen BV2A/BV2B
PO Box 30-547
Taipei, Taiwan
Republic of China

A group of European hams consisting of PA/OH/SM was scheduled to arrive in Taipei for 7 days of operating from April 16 through 23, 1984. The group was granted the special callsign BV0AA instead of BV0DX as previously reported.

Gerben PA0GAM, who initiated the DXpedition application, arrived in Taipei on April 16 with his IC-740, amplifier (GLA1000), and a tribander vertical. Gerben advised us that SM0GMG had not embarked on the airplane because of his father's illness. Poor Lars! He missed the trip and so did not come up in the BV0AA's logs; we are greatly distressed that this

OH2BH (left) and PA0GAM at BV0AA.

Left to right: L. C. Huang (CRA Deputy Secretary), Matti OH2BH, Gerben PA0GAM, Michio JA1MIN, and me (Tim BV2A/BV2B).

happened to him. Matti OH2BH arrived two days later, bringing along with him two transceivers (FT-757GX), amplifier (FL2001), and a Hy-Gain 2-element beam. Matti picked up Michio JA1MIN to replace SM0GMG in the group.

Under the bright moon, the group started promptly to erect the beam antenna tor the betterment of DX QSOs. The job was completed very quickly as the mast pipes and guy wires had been ready for use. Everyone showed enthusiasm and close cooperation to commemorate the special day—World Amateur Day—in addition to their DXpedition activity. Incidentally, OM Barry Goldwater K7UGA, visiting here, had been informed of the DXpedition so he could enjoy some relaxing along with his busy official duties.

Last year, I reported in detail the DXpedition of the Italian Blue Team, and following that many are still questioning me about the possibility of visitors operating in this country and how to get the permission. Yes, it was a problem with us, but now Chinese authorities in Taiwan have granted three permits to three different groups. Individual visitors can be permitted to work as "second operator" at BV2A/BV2B. It indicates that we are agreeing to the ham's activities.

What will be next? The Chinese authorities have gradually granted more privileges to group visitors; they are allowed to use 7 MHz besides the 10-, 15-, and 20-meter bands. 144 and 430 MHz will be allowed for the next DXpedition group, then scheduled to arrive in Taipei on June 8th. The PA/OH/JA operators of BV0AA had a nice score of approximately 12,100 QSOs covering 77 countries during the week of operation on the frequencies mentioned above. The outcome was considered good as propagation was FB.

As before, all visitors relaxed after their task was over and were entertained with sightseeing and a dinner party given by the China Radio Association (CRA), where they were met by many VIPs and old oldtimers.

Representing NCDXF, OH2BH presented to CRA a 2-element beam antenna to foster goodwill and to promote more ham activities in this country. We thank the NCDXF for its thoughtful plan! Also, we are happy to own an FT-757GX and FL2001 amplifier left behind by the expedition group at our request. Together with the beam antenna, we have pledged to establish a third BV station in this city. I am happily accepting a membership in NCDXF, by the recommendations of PA0GAM and OH2BH.

The last two expedition groups have shown us something different in radio-operating technique; all visitors are very skillful and well-disciplined. Also they brought in new amateur-radio equipment, synthesized, compact, and efficient, and often gave surprises to other users who also are quite interested in electronic technology.

A local newspaper reported on this friendliness, saying that it made the public more informed of the unique quality of world amateurs. China Radio had a 15-minute program introducing amateur radio through its nationwide net. One of the local TV stations approached us for an interview, but a little too late.

Another DXpedition, from Japan, is (as I write) arriving soon; the callsign will be BV0AB or BV0JA.

FLASH! The Chinese authorities have decided to grant 10-12 ham-station licenses in the near future! I will report the details later.

THE 9Y-8P-LINK REPEATER PROJECT

This month we will look at an experimental project in which the TTARS and the Amateur Radio Society of Barbados (ARSB) have been jointly participating—the 9Y-8P-Link Repeater Project.

During the first half of 1983, this project, which had been in the planning stage for several years, finally became a reality, and the islands of Barbados and Trinidad were linked via the two-meter band.

This VHF repeater system is the first stage in a plan to link all of the Caribbean islands on 2m and is being used as the proving ground for the plan. Such a VHF link is desirable between the islands especially in times of emergency and disaster. Many of the Caribbean islands are vulnerable to the hurricanes that can, and often do, appear in this area during the period June to October. During these times, the islanders often have to rely on amateur radio as their only means of reliable communications.

The importance of having well-equipped and organized amateur-radio operators may easily be seen if you were to review the disaster that engulfed the island of Dominica when hurricane David wreaked havoc there for 8 hours on August 30, 1979. The following year it was St. Lucia's turn to suffer a similar fate with the passage of hurricane Allen. In both cases, amateur radio played leading roles in bringing relief to the affected communities, and they have been reported in the pages of *73*—the Dominica disaster in the May, 1980, issue by myself, under the title "Hurricane." The planned link repeater system is part of the ongoing effort to improve emergency communications throughout the region while at the same time enhancing our day-to-day contact with our neighbors. In the following paragraphs, I shall give a description of the system as it currently is (May, 1984) and comment on its success to date.

On the Barbados end of the link, the repeater site is located at Mount Misery; at 329 meters above sea level (ASL), it is the second highest point on the island. Mount Misery is actually the location for one of the communication centers of Barbados External Telecommunications, Ltd., (BETL)—formerly Cable & Wireless—the company that handles international communications for the island. BETL kindly allowed the ARSB the use of the site and space on one of their 62m towers.

The repeater is a Yaesu FTR-2410 with an input on 144.710 MHz and output on 145.310 MHz. The antennas used are a pair of Ringo Rangers with a vertical separation of 22 meters. The receive antenna is located at 54 meters above ground level (AGL) and the transmit antenna at 32 meters AGL. In addition to being the link repeater, it also serves as a secondary (or backup) repeater for the island, should the primary system on 146.310/.910 MHz fail.

The link to the Trinidad repeater is effected with an Icom IC-290. This transceiver drives an 80-Watt amplifier into a 15-element vertically-polarized yagi 20 meters AGL, pointed at Trinidad. The IC-290 transmits on 147.330 MHz and receives on 147.930 MHz—the frequencies used by the 9Y repeater. The IC-290 is interfaced to the 8P repeater via a homebrew interface designed and constructed by Ron Armstrong 8P6BN.

On the Trinidad end of the link, a Yaesu FTR-2410 repeater also is in use, driving a 100-Watt amplifier into a 4 × 4 element yagi array. The site is on Cumberland Hill in the northwestern part of the island. The location is 548 meters ASL and we have been provided space on a 62-meter tower through the kind courtesy of the local TV station. The antennas are located at the 46-meter level.

The system operates as follows. When a signal is received by the Barbados repeater on 144.710 MHz, it keys up that repeater and the signal is broadcast locally on 145.310 MHz. The interface interconnecting the BP repeater and the IC-290 also senses this signal and puts the IC-290 into the transmit mode, sending this signal across the Caribbean Sea to Trinidad on 147.330 MHz. The transmission is received by the 9Y repeater and simultaneously rebroadcast on 147.930 MHz for the reception of Trinidadian hams. When the signal being received by the 8P repeater on 144.710 MHz ceases, the interface unit returns the IC-290 to receive mode, and the 9Y repeater also returns to the standby mode.

When a signal from the 9Y end keys up the 9Y machine, the 147.930-MHz output signal is received by the IC-290 in Barbados. This triggers the interface unit which switches on the 8P machine, and the original transmission is then simultaneously rebroadcast in Barbados on 145.310 MHz.

The distance between the two repeater sites is about 338 km, and with the antennas at each end being less than 600 meters ASL, it can be seen that this is a very long path for reliable VHF communications. This fact has made itself evident over the past 10 months or so, and the reliability of communication via the system has often left much to be desired. There is much multi-path fading which, after the original novelty had worn off, has rendered operation through the system a frustrating experience. Many QSOs were had on the "ups" in the pathway, but only the patient operator waited through the "downs" to continue the QSO on the next "up"!

The system as originally set up has proven unsuitable in its original objective and an alternative plan has been pressed into operation. On March 10, 1984, the technical officers of the ARSB (8P6BN and 8P6FV) changed the link transceiver over to the J3 repeater on the island of Grenada. This repeater operates on 146.160/.760 MHz. Grenada, due to its geographical location, forms a most suitable stepping stone to break the lengthy path between Barbados and Trinidad.

As I write this, the new system has been in use for about six weeks and has met with very good success. It has allowed reliable communications between hams located on the islands of Barbados, Grenada, St. Vincent and the Grenadines, Trinidad, St. Lucia, and even some of the islands further north. In order to access this new system then, which is now a J3-8P link, stations must access either the J3 or the 8P repeater as the 9Y repeater is no longer a part of the system. On the Trinidad end, therefore, this has resulted in very restricted access to the system, mainly on account of the Northern Range, a mountain range with highest peaks of just over 1000 meters, that is along the entire northern coast of the island. As a result, only a few stations in ideal locations on Trinidad, running higher power (100 W and up) into multi-element directional antenna systems, are able to access the J3 repeater and get into the new link. Later this year it is hoped to install an interface unit similar to the one used in Barbados to link the J3 and 9Y repeaters. It is expected that when this is completed, all 9Y stations will have access to the link.

The ARSB has plans to improve the installation by the acquisition of a set of duplexers to relieve some desensing and intermodulation problems that have plagued their end from time to time. It is interesting to note that since the change has been made linking the J3 and 8P repeaters, the amplifier on the Barbados end has been cut off and the repeater run barefoot—just 10 W or approximately 500 W erp—and reliable two-way communications have been maintained.

PUBLIC SERVICE ASSISTANCE

On March 25, 1984, the TTARS provided the communications necessary for an International Go-Kart Race Meeting. The meeting was sponsored by the local Karting Club at the Go-Kart track at Chaguaramas on the northwestern peninsula of the island. This sport has recently been revived in Trinidad, and the organizers, seeking a reliable communication network, approached the TTARS for assistance. The TTARS members who volunteered their services were treated to a day of thrills but few spills, while at the same time assisting with the smooth running of the event. The 9Y participants included -4M, -HM, -WG, -VAN, and -GR.

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003, Trades 463-1886 San Diego, 827-5732 (Reno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Jose CA

Bay area's newest amateur radio store. New & used amateur radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1775A S. Winchester Blvd., Campbell CA 95008, 370-6665.**

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Azden, AEA, Kantronics, Santec. Full line of accessories. No sales tax in Delaware. One mile off I-95. **Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.**

Boise ID

Rocky Mountain area's newest ham dealer. Call RJM first for AEA, Azden, KDK, Ten-Tec, Butternut, Cushcraft, and more! **RJM Electronics, 4204 Overland, Boise ID 83705, 343-4018.**

Preston ID

Ross WB7BYZ has the largest stock of amateur gear in the Intermountain West and the best prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

Littleton MA

The reliable ham store serving NE. Full line of ICOM & Kenwood. Yaesu HTs, Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delta protectors, ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. **TEL—COM Electronic Communications, 675 Great Rd. (Rt. 119), Littleton MA 01460, 486-3400/3040.**

Livonia MI

Complete photovoltaic systems. Amateur radio, repeater, satellite, and computer applications! Call Paul WD8AHO. **Encon Photovoltaics, 27600 Schoolcraft Road, Livonia MI 48150, 523-1850.**

Hudson NH

Look!—hams, SWLs, and experimenters: parts, books, gear, antennas, towers. Call for quotes. **Polcari's ELECTRONICS CENTER, 61 Lowell Road (Route 3A), Hudson NH 03051, 883-5005.**

Albany, New York
UPSTATE NEW YORK

Kenwood, ICOM, Ten-Tec, Belden, Cushcraft, Larsen, Hustler, ARRL, Hy-Gain, B&W, MFJ, Mirage. New and used equipment. Serving the amateur community since 1942. **Adirondack Electronics, Inc., 1991 Central Avenue, Albany NY 12205, 456-0203** (one mile west of Northway exit 2W).

Columbus OH

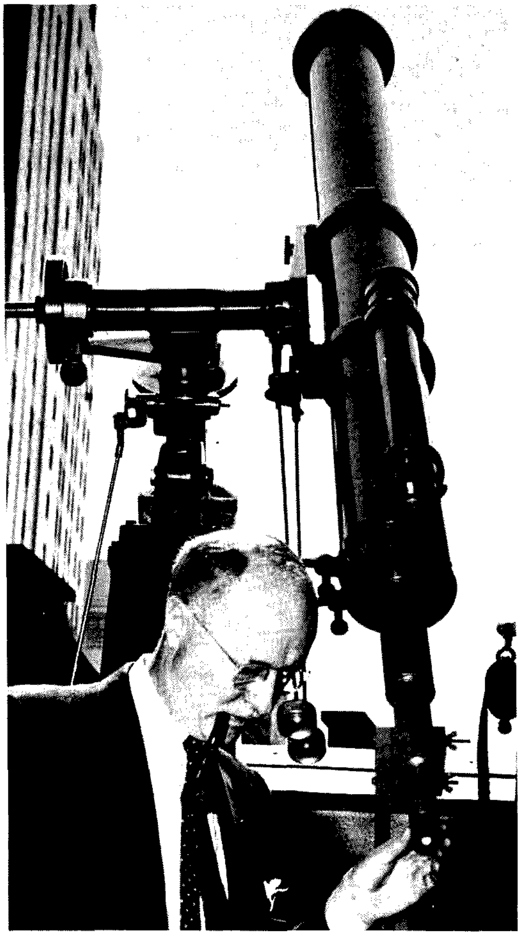
The biggest and best ham store in the Midwest featuring Kenwood and other quality products with working displays. We sell only the best. Authorized Kenwood service. **Universal Amateur Radio, Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

Dallas TX

IBM PC/XT kits, supplies, expansion products; video restorer kits for pay TV, CATV, satellite hobbyists' electronic project kits/appnotes. More than 9000 parts in stock: semiconductors, ICs, discretes, video accessories, tools, audio, automotive, cabinets, computer peripherals. Please write for your free 60-page catalog: **Sahet Electronics, 13650 Floyd Rd., Ste. 104, Dallas TX 75243; 783-4950 (formerly I.E.).**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the November '84 issue must be in our hands by September 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.



PROPAGATION

It is with deep sorrow that we note the passing of our good friend John H. Nelson on May 23, 1984.

For 15 years, John had the final word in 73, his propagation forecasts guiding the dreams of DXers throughout the world. He will be missed.

STAR WARS

Zaaap, goes the laser beam! But if that was my ship doing the fighting, you can bet I'd spend the extra money for a radar system to aim the lasers and not send a Wookie to do a radar's job.

Lasers and fiber optics are the way things are going for communications. It's the only system which provides the bandwidth needed to get enough information through in a short time. Just look at the way we've had to screw up television, which is lousy enough, in order to send even a fuzzy slow-scan picture over amateur-radio channels!

It's information and bandwidth. If you want to send more information per unit time, it takes more bandwidth. A normal television picture takes about four MHz of bandwidth. With slow scan, we cut the lines to one-third and the pictures per minute from 3,600 to seven... and presto! We can get the information through a 2,500-Hz bandwidth window. It's fuzzy and there are eight seconds for the voices from the adjacent channels to tear up the picture, but those hardy SSTV folk keep at it, getting very nice pictures occasionally.

The information for TV pictures is analog, so it suffers from noise. If you record a TV program with your VTR and then re-record it on a second VTR, you'll see the degradation of the analog signal. Each copy is called a generation, and it doesn't take many to lose most of the information. It's the same with audio tape recorders. With digital communications, the hundredth generation is identical to the first—quite a benefit. There's no gradual signal loss to noise.

It was this aspect of digital communications which got me involved with RTTY 35 years ago. We had a ball in those days. Under the guidance of John Williams W2BFD, we had a wonderful two-meter network running, complete with a RTTY repeater atop the New York City Municipal Building. RTTY wasn't permitted on the other bands then. Oh, I experimented with it on 80m and made contacts as far as California (W6NRM), but I had to use on-off keying instead of frequency shift, so it wasn't nearly as effective.

On two meters we had autocall and auto-answer going fine. We could set our systems to print everything sent on the channel or to be selective and only look for messages addressed to our station. Paper was cheap, so I let my machine copy it all, wading through a floor full of copy when I'd get back from a weekend away.

Now, of course, you don't need paper unless you want a permanent copy for some reason. And instead of those big, noisy clunker Model 12 Teletype® machines, we use an inexpensive computer such as the Commodore 64. Even an old used $50 TI-99/4A will do it just fine. And you use a disk to save the weekend of information instead of a hundred yards of paper. You really should try RTTY now.

It's getting time to get the paper out of communications—even with magazines. I've been thinking about that. The old bandwidth problem again. If you are going to get *73* electronically, it is going to take either a whole lot of bandwidth or a lot of time. The halftone pictures we use in printing are darned near digital. Look at 'em with a good magnifying glass. By making a few more lines per inch, we could go digital. Or we can send four bits for each halftone dot and have 16 levels of dot. We

Counter-Productive Basics: Part II

How hard can counting be? K4IPV tells us where the errors occur and how to fix them.

Joseph J. Carr K4IPV
5440 So. 8th Road
Arlington VA 22204

In the first installment of this series, we discussed the basics of digital frequency counters (DFC). We started with a discussion of the basic J-K flip-flop and then proceeded to develop its role in binary- and decade-counter circuits. In this installment, we will discuss applications of the DFC and some user problems.

DFC Input Circuits

The input stages of the DFC amplify and waveshape the input signal to make it compatible with the digital logic circuits of the counter. Most of the time, the input signal will not be a square wave or fast-risetime pulse as required by the digital circuits, but rather it will be an ac signal.

Fig. 1 shows a counter-input stage. The input amplifier builds up the signal and feeds it to the trigger circuit (often a Schmitt trigger). At frequencies below UHF, most counter-input amplifiers have an input impedance of 1 megohm shunted by some capacitance (often 20 pF). At VHF frequencies, however, this can lead to false counts or lowered sensitivity because of standing waves on the line. At those frequencies, the input cable acts like a transmission line. If this problem is experienced, it is possible to overcome the limitation by placing a 50- or 75-Ohm barrel attenuator in the line at the counter input. Provided that only 1 to 6 dB of attennuation is used, the loss of signal is balanced by achieving a matched input impedance.

The input signal very rarely will be the nice, clean square waves required for proper operation of the digital logic-circuit elements used to make a counter. The signals also may be too low in amplitude to operate the digital logic circuits or may be too noisy. Remember, a TTL flip-flop needs to see fast rise and fall times (i.e., good square waves) and amplitudes greater than 2.4 volts or they will not operate properly.

The input signal, then, is passed through two processing stages: an amplifier and a trigger. The amplifier is a wideband voltage amplifier with enough gain to build up the minimum allowable signal (usually 25 to 100 mV) to a level great enough to drive the trigger stage (i.e., 500–1000 mV).

The trigger stage is a

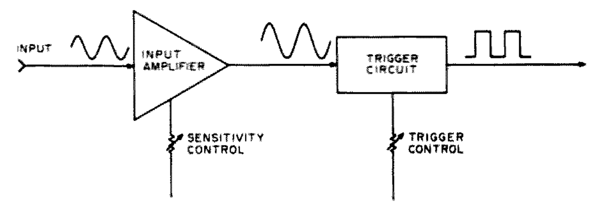

Fig. 1. Counter-input stage.

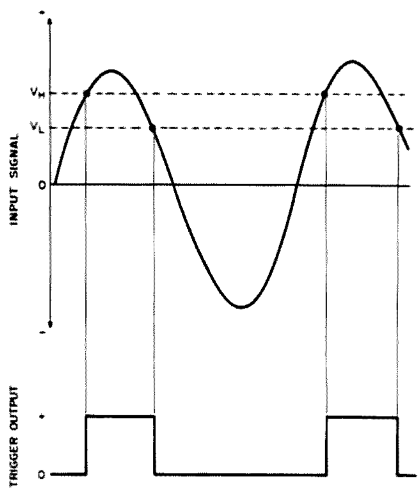

Fig. 2. Normal operation of a trigger circuit.

Schmitt-trigger circuit with a built-in hysteresis. This type of circuit is used to clean up irregularly shaped signals by making them into square waves. Fig. 2 shows the normal operation of a trigger circuit. The output snaps high when the input signal crosses the lower hysteresis limit and remains high until the signal crosses the upper limit in a negative-going direction. The hysteresis window is the quantity $(V_u - V_L)$. Note that the trigger output possesses the shape and amplitude required by the digital circuits that it drives.

It is a fundamental rule that input signals must cross *both* hysteresis limits or no count will be entered by the DCA. In Fig. 3, (a) shows the required situation: the input sine wave crosses both limits, but in (b) the sine wave crosses only one of the window limits, so no count is registered on the DCA.

Some counters have a *trigger-level* control that allows the user to adjust the position of the window over a wide range. Other models use a three-position switch labeled +, preset, and −. The switch allows the window to be placed in any of three locations (see Fig. 4). A continuously-variable trigger-level control allows positioning of the window *anywhere* within the range. Note that neither the continuously-variable nor the three-position-switch type of controls varies the *width* of the window $(V_u - V_L)$, but only the position. However, some counters are equipped with a trigger-amplitude control which *does* allow the operator to vary the width of the hysteresis window.

There are several factors that tend to reduce the accuracy of an electronic counter, and these can be grouped as *inherent errors* or *signal-related errors*. The inherent errors are a function of the quality, age, and history of the individual counter. Little can be done about these unless their source is a serious need for recalibration of the timebase. Signal-related errors, on the other hand, often are correctable by proper manipulation of sensitivity, trigger-level, and trigger-amplitude controls.

Inherent Errors

There are two sources of inherent error in all frequency and period counters: timebase error and a ±1 count ambiguity.

The timebase error is expressed in terms of a percentage or in parts per million. The error from timebase inaccuracies is directly reflected in all measurements of frequency or period. For example, suppose a 1-Hz timebase is off by 30 Hz (e.g., it is actually 1,000,030 Hz instead of 1,000,000 Hz). This is an error of 30 parts per million (30 ppm), which is [(1,000,030 − 1,000,000)/1,000,000] × 100, or 0.003%.

The measurement error due to timebase inaccuracy is constant regardless of the frequency being measured. That is to say, there will be a 0.003% error at 1 kHz and the same 0.003% error at the maximum frequency that the device will measure. For example, a 27-MHz signal would be measured with an error of (27 MHz × 30 Hz)/MHz = 810 Hz. This means that a counter reading 27,000,000 indicated that the actual frequency is 27 MHz ±810 Hz. In other words, the actual frequency lies between 26,999,190 Hz and 27,000,810 Hz.

If the timebase frequency is low, then the counter reading will be high.

Total timebase inaccuracy is the sum of several individual errors: *initial error, short-term stability, long-term stability, temperature change,* and *line-voltage change*.

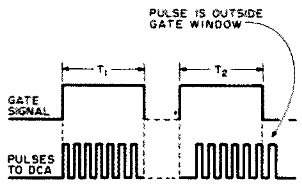

Fig 5. Lack of synch between input signal and timebase.

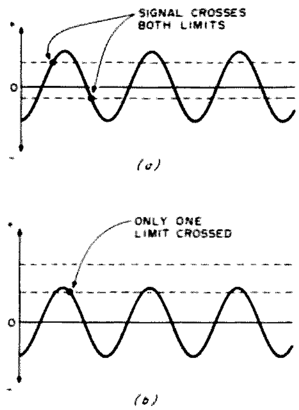

Fig. 3. The sine wave crosses both hysteresis limits in (a) but not in (b).

The *initial error* is the calibration error at the time the timebase is intially adjusted at the factory, or at recalibration in a metrology laboratory. Different methods are used to measure the timebase frequency, but in most cases the timebase-oscillator frequency is compared with standard-frequency broadcasts of the National Bureau of Standards radio stations WWV, WWVB, or WWVH. Alternatively, it might be compared with the output of a cesium- or rubidium-beam atomic clock.

The *short-term stability* is the timebase-oscillator frequency drift per day. *Long-term stability* is the frequency drift per month, and is often designated the *aging rate*.

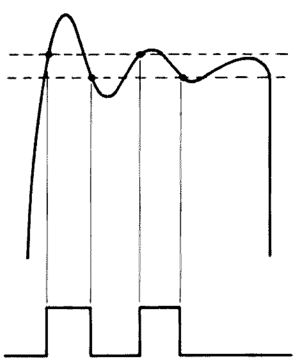

Fig. 6(a). Spurious counts created by extra crossings.

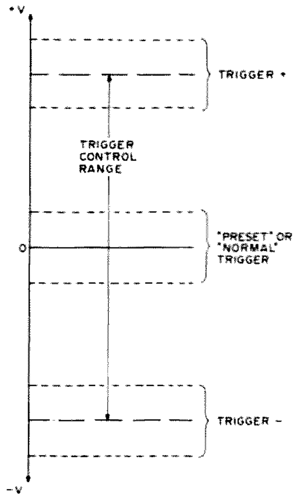

Fig 4. Three-position trigger-level control.

The *temperature-* and *line-voltage-stability* specifications refer to the frequency change over the 0–50° C temperature range, and ±10 percent line-voltage change, respectively.

There are four different classes of counter timebase: ac *line, room-temperature crystal oscillator, temperature-compensated crystal oscillator* (TCXO), and *oven-controlled crystal oscillator*.

The use of the 60-Hertz-ac line as a counter timebase is limited to the very cheapest models and a few low-grade older units. Even low-cost units today have a crystal

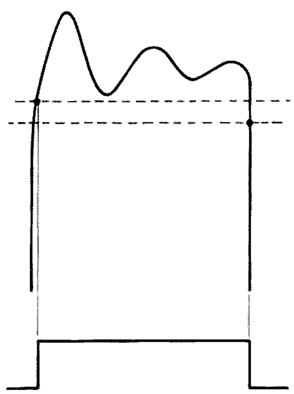

Fig. 6(b). Trigger-level control avoids spurious counts.

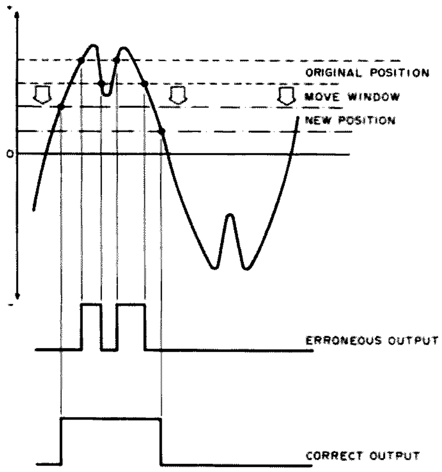

Fig. 7. Harmonic distortion of sine-wave-input waveforms.

	XTAL	TCXO	OVEN
Long term aging (per mo.)—	5×10^{-7}	2×10^{-7}	5×10^{-10}*
Short term aging (per day)—	—	—	10^{-10}
± 10% line voltage—	10^{-7}	10^{-8}	10^{-9}
Temp. 0-50°C (ambient)—	10^{-8}	10^{-7}	10^{-9}

*After 24-hour warmup.

Table 1. Typical stability specifications.

oscillator for the timebase, and even though the crystal is operated at room temperature, it provides better accuracy than the 60-Hz power mains. Note that power companies typically will quote very high accuracy figures for their power plant's operating frequency, but these are frequency averages over a very long time. The short-term accuracy, which is what concerns counter users, is terrible.

The TCXO is an encapsulated oscillator that is specifically compensated against temperature changes. The TCXO provides at least an order of magnitude better stability than room-temperature oscillators. The TCXO is less expensive now than in the past, so even moderately-priced counters now offer TCXO stability.

The oven-controlled crystal oscillator places the crystal (and in some cases the rest of the oscillator circuitry) inside an oven, or thermal chamber. Thermostat ovens are considered an order of magnitude better than TCXO designs, while the proportional-control type of oven is from one to two orders of magnitude better than TCXO.

Table 1 lists typical stability specifications for several models of counters by several different manufacturers. Note that the short-term stability is given only for the oven type of timebase. The TCXO and crystal oscillator must be operated for a full 24 hours before the stability reaches the specified level. At operating times less than 24 hours, the stability is poorer. Some models use a separate regulated power supply for the TCXO that is not turned off by the main power switch. Rechargeable batteries are used in portable models for the same purpose, so the TCXO is not turned off while the counter is being transported between job sites.

The ± count ambiguity is caused by the lack of synchronization between the input signal and timebase. This is illustrated in Fig. 5: During period T_1 seven pulses are gated into the DCA while during T_2 only six pulses reach the DCA. On some subsequent count, it may be that eight pulses are gated into the DCA. One fundamental rule for all digital-counter instruments is that there is an error of ± count of the least significant digit. In other words, a counter that reads, say, 10,000 Hz is measuring a frequency that lies between 9999 Hz and 10,001 Hz, i.e., 10 kHz ±1 Hz.

The ± count ambiguity produces an error that is inversely proportional to the frequency being measured and the gate time:

$$\text{Error (\%)} = \pm 100/fT$$

where f = the frequency being measured, in Hertz, and T = the time the gate is open, in seconds.

For example, let's find the percentage error due to ±1 count ambiguity at (a) 2 MHz, and (b) 27 MHz, for a gate time of 1 second.

Solution:

(a)

Error = $\pm 100/fT$

Error = $\pm 100/(2 \times 10^6 \text{ Hz})$ (1 sec)

Error = ± 0.00005 percent

(b)

Error = $\pm 100/fT$

Error = $=100/(2.7 \times 10^7 \text{ Hz})$ (1 sec)

Error = ± 0.000004 percent

The error is ±1 count regardless of the frequency being measured, so the *percentage* of error decreases for higher frequencies: Compare (a) and (b) above.

Signal-Related Errors

Poor signal quality can introduce errors that add to or subtract from the true count. Most of these errors

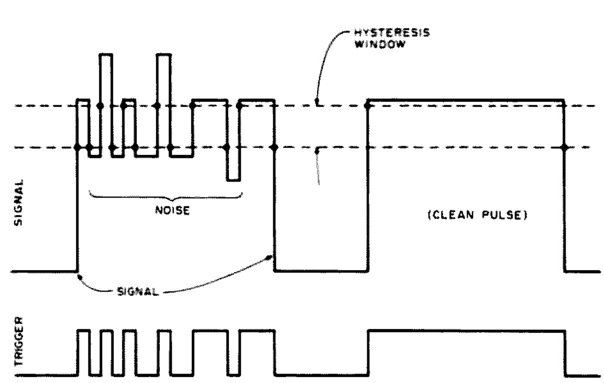

Fig 8. Impulse noises cross the hysteresis window.

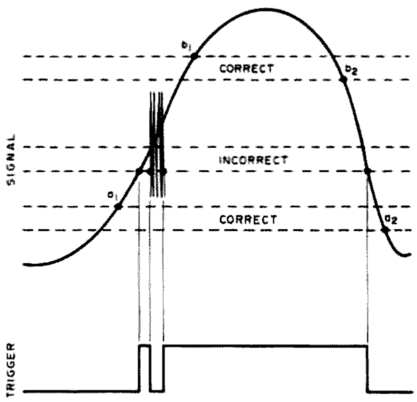

Fig 9. Correct and incorrect window positioning.

result from hysteresis-crossing or noise on the signal.

Trigger errors occur because the input signal crosses the hysteresis window limits too many or too few times. We saw in Fig. 3(b) that a signal will fail to increment the DCA if it does not cross *both* limits of the hysteresis window, causing too low a count.

Fig. 6(a) shows how severe ringing on a signal can create extra, spurious counts of the DCA if the trigger-level control is adjusted so that the ringing portions of the signal cross the limits, creating additional "input" pulses, a two-count error. The cure is to adjust the trigger-level control so that the ringing portions of the waveform fall outside the window limits—see Fig. 6(b).

The same problem exists on sine-wave-input waveforms (Fig. 7) that have a large amount of *harmonic distortion*. The cure is the same, however. Readjust the trigger-level control so that it is operating over a lower portion of the waveform.

Similarly, impulse noise riding on the signal can have an amplitude sufficient to cross both limits of the hysteresis window. An example of this phenomenon is shown in Fig. 8, in which a pulse in a symmetrical wave train is carrying impulse-noise artifacts. In the case shown, the noise bursts cross the window limits and thereby force the trigger output to create extra pulses instead of just one.

Once again, the correction requires readjustment of the trigger-level control to a point further down the waveform. In the case of a non-square wave, the noise may appear on the leading or trailing edges and still cause the problem. Fig. 9 shows the proper and improper positions for the hysteresis window on such a waveform.

Note that filtering of the noise is not usually feasible because of the bandwidth requirements of the input amplifier.

Fig. 10 shows a type of noise error that is particularly troublesome on period measurements. In this example, noise rides on a signal that has a shallow slope, and so creates a band of uncertainty around the signal. The trigger circuit should produce a high output when the signal crosses the upper limit and drop low again when the signal crosses the lower limit, but noise impulses adding to or subtracting from the signal amplitude could provide premature or delayed trigger transitions. The correct duration of the trigger output pulse in Fig. 10 is ($t_5 - t_2$), but under worst-case conditions the actual duration may be as much as ($t_6 - t_1$), and that amount represents a considerable error.

The solution for this problem is to cause the signal to slew through the hysteresis band as *rapidly* as possible. Two methods can be used to implement this solution. One is to narrow the window by adjusting the trigger-amplitude control, and the other is to increase the waveform's slope by preamplification.

On some types of signal waveform it is sufficient to adjust the trigger-level control so that the counter triggers on the *steepest* portion of the waveform. On sine waves, for example, this point occurs at zero crossings, but on other waveforms it may occur elsewhere on the signal.

One final type of signal-related problem involves the case where successive cycles have varying amplitudes. You can position the trigger so that it satisfies some of the cycles—see Figs. 11(a) and 11(b)—but others fall outside of the hysteresis window. Again, the solution may be resetting the trigger control.

How Much Sensitivity?

It is possible that a system can have too much sensitivity. While that statement may seem heretical, there comes a point where the sensitivity is too great because it permits noise or distortion artifacts to cross the window limits. In some cases, therefore, our "fix" for certain problems is to reduce the sensitivity or insert an attenuator into the line. ■

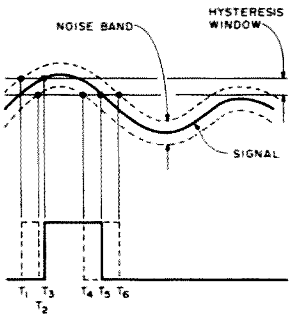

Fig. 10. Noise band along a shallow-slope waveform.

Elementary, My Dear: Watts 'n' Swr

Stop guessing. Build this no-nonsense VHF/UHF wattmeter and save your hard-earned cash.

Here's a project everybody can use—a cheap, reliable wattmeter that can be used anywhere from 50 to 500 MHz. It uses an etched-line circuit for coupling and has two power ranges. Additionally, it can be calibrated to measure swr as well!

The idea for this project grew out of discussions the Split Rock ARA had back in 1980 concerning a possible club project. Among the many ideas kicked around was one for such a wattmeter, although at the time an unrealistic figure of $15.00 for the total cost was anticipated. As expected, the project never got off the ground.

I stuck with the concept and over the years tinkered with various designs. Somewhere in the past I had stumbled upon a circuit that used an etched transmission line and coupler, so a trip to the technical archives in the attic revealed what I needed. The big problem was that the etched line was nowhere near 50 Ohms! This wouldn't do at all. After all, what good is a 500-Ohm wattmeter?

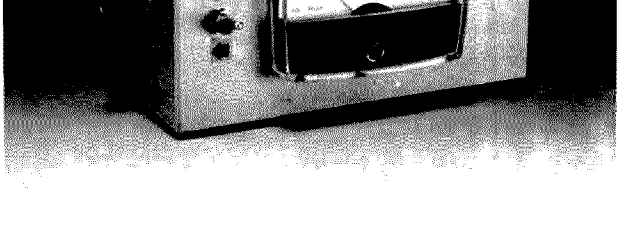
Additional research revealed that the dimensions of a 50-Ohm stripline etched on G-10 epoxy board were close to 1/10 inch in width, with any length usable. After confirming this with Steve Katz WB2WIK, I began carefully etching test boards in the darkroom using precision rulers and masking material cut with an X-acto® knife.

After about four prototypes, a board was produced which, when connected between two type BNC connectors (using the unetched side of the board as a ground plane), exhibited no reflected power on a Bird Model 43 wattmeter connected in series and terminated at 50 Ohms. Voila! I had done it. Now to the nuts and bolts of the circuit!

I should clarify any additional comments by saying that this unit is really a bi-directional coupler. As such, it can be used to measure swr or power—whichever you prefer. It samples a small amount of rf on the transmission line through a coupling line which is terminated in the middle. At either end, type 1N60 diodes are used to rectify this small sampled voltage. Add a few switches, pots, and a meter and that's it! Period.

As I just mentioned, rf energy traveling on the 50-Ohm section from input to output is sampled by the −30-dB coupler—sort of like winding a link coupling at HF frequencies. D1 and D2 can be almost any kind of point-contact diode, but the best choice would be a 1N60 due to the better performance characteristics at VHF/UHF.

The sampled, rectified dc voltage is then routed to R2 or R3 via SPDT switch S1. These two potentiometers set power ranges or can be used to set frequency ranges. Note that as with most wattmeters that use coupling lines, the degree of coupling



Front view of wattmeter.

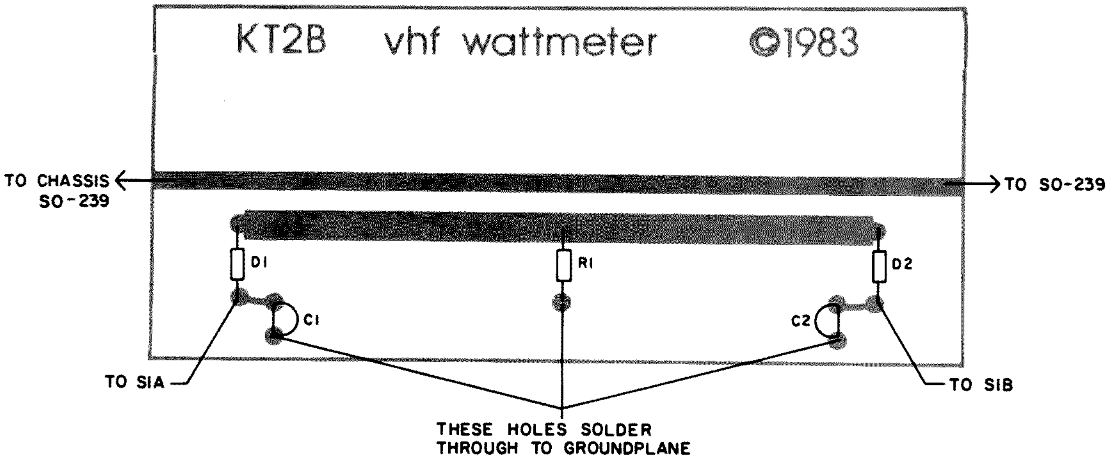


Fig. 1. PC-board overlay for parts.

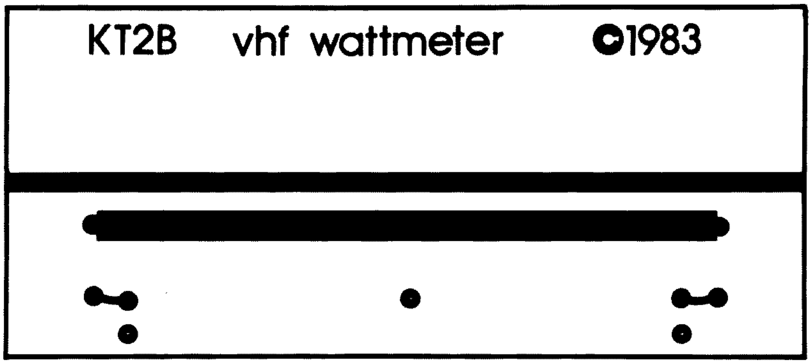

Fig. 2. Master art for PC board.

rises with the frequency chosen and decreases with a lower frequency, so that different readings will be evident on different bands for the same power level measured.

Also note that while the actual power measurement and its relation to the meter scale is a function of a logarithm, the relation between decades of measurement is a linear function. This allows the use of one meter scale on any band. Power levels up to 500 Watts can be measured accurately with this unit—typically within 10% of a Bird 43—but I haven't tried anything higher. Teflon™ board would be a better choice for higher power levels.

R1 on the sampling line functions as a termination, and you may have to tinker with it a bit to determine coupling characteristics. I found a value of 27–33 Ohms to be fine. C1 and C2 function as rf bypass capacitors. The best way to mount the PC board is to suspend it between two connectors—either type SO-239 or BNC female. Use finger stock or braid to make a good connection from the ground lug to the backside of the PC board.

I would suggest installing the meter in the case *first* before doing anything else. A recommended unit would be the Radio Shack #270-1751, 50-μA movement. It's inexpensive and has a big scale that is easy to modify. Next, mount the two switches, S1 and S2, on either side of the meter face. Prepare the PC board with all components as shown in Fig. 1, along with appropriate lengths of wire to connect to each switch. Install the side connectors of your choice along with about 1" of braid or finger stock for the ground connection. Finally, install the completed PC board by suspending it between the center pins on the connectors and then soldering the center pins to the 50-Ohm etched line. Solder the braid to the back of the double-sided board.

Calibration can be achieved with use of a known, accurate bridge or wattmeter, such as a Bird Model 43 or similar unit. Set the unit up to the ranges you desire by adjusting the ten-turn pots, R2 and R3. For example, you may wish to measure the output of two

D1, D2	1N60-type diode or similar	Radio Shack	10 @ .99
R1	33-Ohm, 1/4-Watt resistor	Radio Shack	5 @ .39
R2, R3	15-turn, 3/4-Watt, 500k pot	Jameco #43P	$1.19
S1, S2	SPDT Minlswitch	Jameco #JMT121	$1.49
C1, C2	.001 disc, 50 volts	Radio Shack	2 @ .39
J1, J2	SO-239 connectors	Nemal Elect.	$ .79
M1	50-μA movement	Radio Shack	$8.95
Case	LMB TF-780 case	(distributor)	$3.80
			$21.46

mobile rigs; one with 25 Watts at 146 MHz and one with 10 Watts at 440 MHz. Or, if you wish, you can add additional trimpots for additional ranges.

I have included in Fig. 3 a template for a wattmeter scale that can be used instead of the 50-μA scale on the meter. Remove the meter face carefully, using a screwdriver to pry it off. Next, using extreme care not to bend the meter movement, work a small knife or screwdriver under the metal scale on the unit. Pry gently around the corners until it pops free, then slide it out. Use this metal scale as a template to cut the supplied scale to size. Reinstalling the new scale is easy since Radio Shack uses double-sided tape on the face to hold the factory-supplied scales. Snap the cover back on and you're in business.

As was stated before, accuracy has been measured to within 10% or better of a Bird 43 on the desired frequency. If you want, you can remove the meter and remote it, leaving the coupling unit in its own box. This could be handy for mobile installations! If there is interest, I can supply etched, drilled, and plated PC boards for $10.00 each. ■

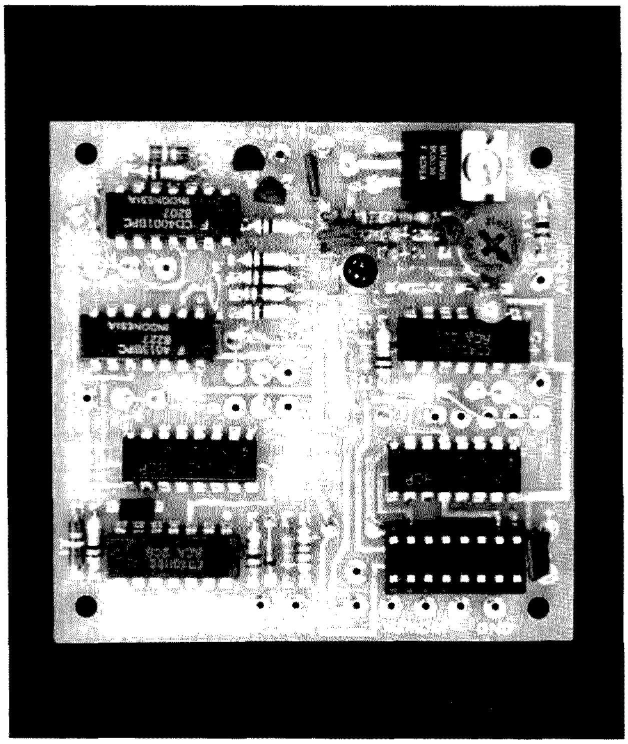
Perfect Timing

Proud of your repeater? Construct this multi-talented identifier and tell the world your who, what, and where.

Does the world really need a new repeater-identifier circuit or, for that matter, a new timer circuit? Why a new one when so many good designs abound?

Well, it was a combination of circumstances and specific needs which don't seem to be satisfied with the existing designs.

Bob's 2-meter repeater, VE2BG, shares a site with a commercial machine, one of several run by the operator. Said gentleman was advised by the DOC (Canada's version of the FCC) that all his transmitters (20 plus) must henceforth incorporate identifiers. Knowing that the commercial models would cost him a minimum of $500 each, he appealed to Bob for an amateur (read "low-cost") solution to his problem.



Identifier-timer board.

At about this point in time, VE2DWG developed a need for an identifier-timer for a proposed 10-GHz beacon. This would, every few minutes, send the beacon callsign plus a message giving the location and a QSL address for reception reports. This message would require about 200 diodes to program a conventional scanning identifier, requiring enough board acreage to grow corn as a sideline. This, plus the thought of installing a smaller number of diodes in 20 or more boards, was enough to convince us that programmable read-only memory (PROM) was the answer to both requirements.

The complication of building a PROM programmer seemed justified by the benefits to be gained. VE2DWG rashly volunteered to undertake this part of the project while VE2AO did the identifier-timer design. Enough said about this aspect of the project, except to note that as a consequence of this we are now able and willing to burn PROMs for those who like the design but don't want to go to the bother of haywiring together their own programmer.

The finished identifier-timer (the term seems to cry for shortening to something like *Identi-Timer*) uses six CMOS chips, a 256×4 (1K) bipolar PROM, a monolithic voltage regulator, and four transistors on a board three inches square to generate CW messages up to 256 bits in length. The addition of one more chip can increase this to 512 bits. Strapping options allow a choice of various timing options or

use as an identifier only. If your junk box is as bare as ours (at least when it comes to the particular parts that are necessary) and you end up having to buy all the components, the total cost should not exceed 25 dollars.

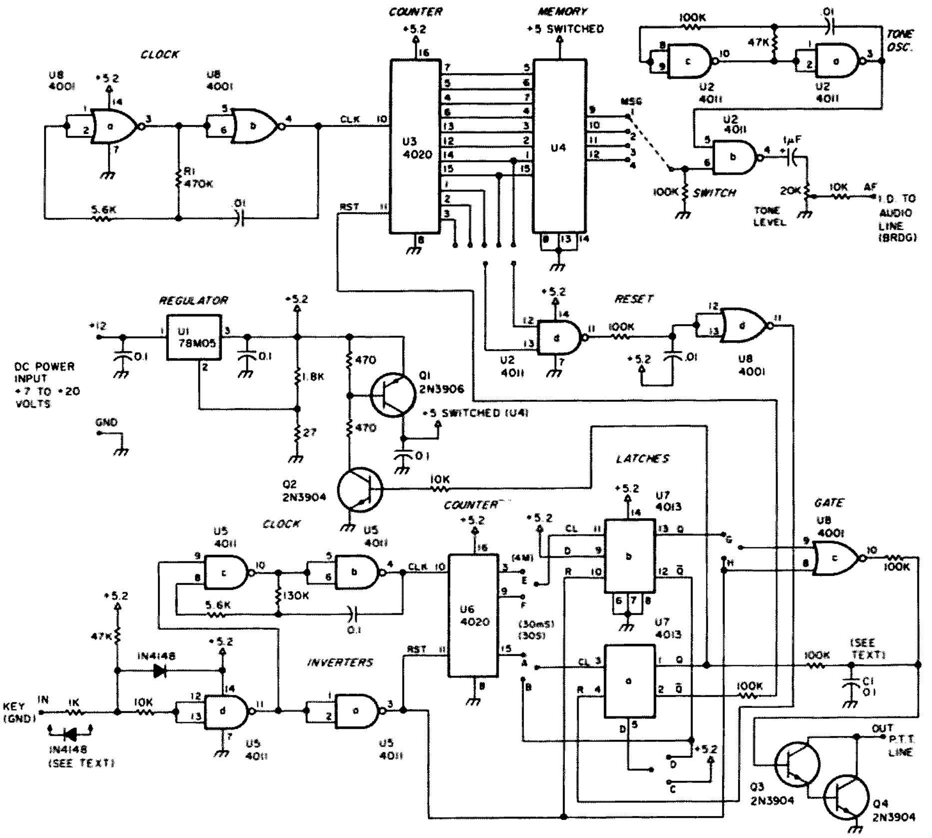


Fig. 1. Identifier-timer schematic diagram.

Construction

Parts placement is shown in Fig. 4. All resistors are ¼ Watt and are mounted flat to the board except for the two 470-Ohm resistors on the base of Q1; these are mounted on end, transistor-radio style. The 20k tone-level potentiometer is a Helitrim Model 91; anything of the same approximate size and lead placement will work. The lead on the voltage regulator should be bent at right angles before mounting, allowing you to secure it with a #4 screw and nut through a hole in the board for this purpose.

All ICs except the PROM were soldered in place on the 20 or so boards manufactured; no failure occurred which would have made the messy job of removal necessary. It hardly seems right to have to use IC sockets costing more than the chips that go in them, but this does necessitate buying good quality chips with minimal failure rates; the choice is up to the builder. A 16-pin DIP socket was provided for the PROM since callsigns do change.

Circuit Description

The unit is divided into two functional blocks: the identifier and the timer circuit. The identifier will be described first, since it is the less complicated of the two. All integrated circuits (except the PROM itself and the on-board voltage regulator) are CD4XXXB series CMOS.

The Identifier Circuit

The basic idea of the identifier is centered around a 256 × 4-bit programmable read-only memory containing the previously-entered bit sequence, in 1s and 0s, that represents the message to be sent in Morse. The address lines of the PROM are scanned in sequence by a binary counter at the desired rate, outputting the stored bits which are used to key an audio oscillator which is fed to the repeater audio line.

The counter is driven by an astable multivibrator clock which runs at a rate which is 16 times faster than the shortest element bit length, equivalent to a dot. For a speed of 10 words per minute, the element length is about 120 milliseconds; this means that the clock bits are about 75 milliseconds, an operating frequency of 133 Hz. The value of R1 can be varied to produce the desired speed; halving the value will double the speed.

A word about the feedback resistor used on this clock and the timer clock: Normally it should have a value of at least two times the R1 value. However, the very fast rise time of the B series CMOS (on the order of nanoseconds) caused erratic clocking of the CD4020 counters, with strange-sounding results in the CW output or inexact time intervals. Reducing the value of this resistor to 5600 Ohms cured the problem when nothing else availed. The problem was not encountered on the U2A/U2C tone oscillator, so the conventional value was used here.

The clock drives U3, a 14-stage CD4020 binary ripple counter. The Q4 to Q11 outputs of the counter (divide by 16 to divide by 2048) are connected to the address lines of the PROM, addressing memory locations 000 to 255 (00 to FF

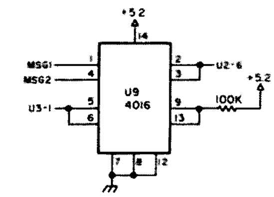

Fig. 2. Optional-message switch.

hex) in sequence. At each step, the PROM outputs four bits on its 9/10/11/12 pins. Only one of these bits is used in a memory cycle, normally bit 1, but any one of the four can be selected by strapping on the board. Alternative messages can be programmed in bits 2 to 4 locations, or a continuation of the message in the 256 bit 1 locations, using the optional memory switch.

A tone oscillator, U2A/U2C, identical to the counter clock except for the operating frequency (and the use of NANDs in place of

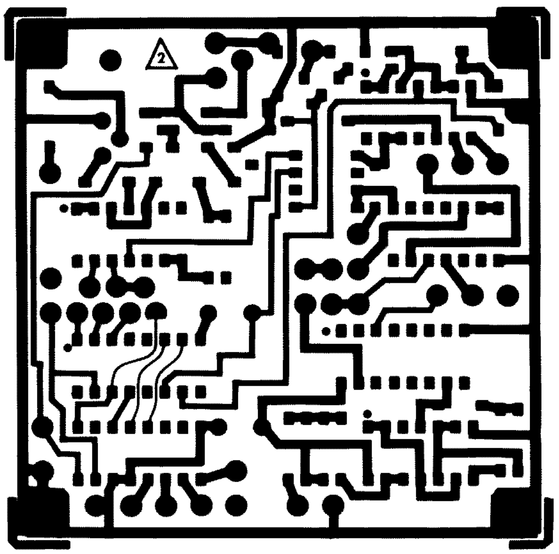

Fig. 3. Circuit board, foil side.

NORs), feeds one input of the U2B two-input NAND gate. The bit output of the PROM feeds the other input, keying the tone on and off at the output of U2B. The tone level control is used to adjust the level of the signal into the 10k series resistor which is bridged on the repeater audio line. Sufficient level is available to cover the majority of setups likely to be encountered.

A number of the counter outputs are made available for connection to a reset circuit consisting of U2D and U8D, used to stop the operation of the identifier after the programmed message has been sent. One or two of these outputs are strapped to the inputs of U2D as required, the two inputs being bridged together if only one output is used. The selectable message lengths are:

- maximum 64 bits: strap to output pin 14.
- maximum 128 bits: strap to pin 15.
- maximum 192 bits: strap to pins 14 and 15.
- maximum 256 bits: strap to pin 1.

The RC network between U2D and U8D delays and stretches the reset pulse applied to U7A, avoiding a possible race condition which could occur because of the slow reset time of the U3 counter.

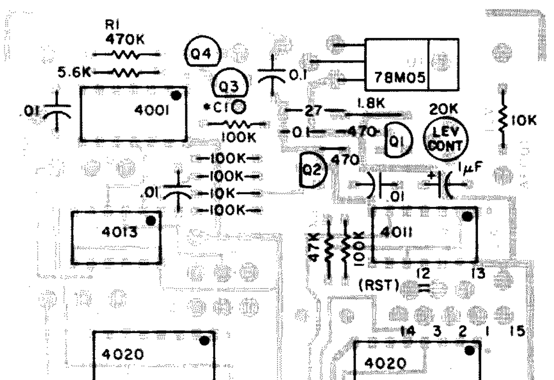

*Fig. 4. Circuit board, component side. *C1, 0.1 uF if required. **Tack-solder 100K resistor from "memory" common to ground, on front or rear of board.*

The Timer Circuit

The external keying input to the timer uses a 1k series resistor when keyed from a dry circuit (such as relay contacts). When keying from the collector circuit of a transistor, replace this resistor with a 1N4148 small signal diode to provide isolation from the collector voltage.

A low on the input to U5D inverter from the keying line produces a high on its output, starting the timer-clock, U5B/U5C, a third astable multivibrator circuit. The following U5A inverter puts a low on the U6 4020 counter reset line and one input of U8C NOR gate. This low enables the counter and is inverted by U8C to turn on the Q3/Q4 Darlington pair, keying the PTT line to ground. Q3/Q4 are capable of driving external loads up to 12 volts, 50 mA. Relay coils should have a parallel reverse protection diode to prevent voltage spikes from damaging the transistors.

The counter clock has a normal pulse width of 15 milliseconds. The three counter outputs provide timed periods of 30 milliseconds, 30 seconds, and 4 minutes, which are the intervals required for the following modes of operation:

- Mode 1 (Straps A, C, E, G): Provides COR timeout of 4 minutes, ID after 30 seconds; will continue to identify every 60 seconds even after timeout, as an indication that the keying input is still seized.
- Mode 2 (Straps A, C, E, H): Will ID after 30 seconds and every 60 seconds thereafter; no timeout function.
- Mode 3 (Straps A, D, E, G): Same as mode 1 except that ID does not continue after timeout.
- Mode 4 (Straps B, C, F, H): Identifies after each transmission, no timeout function.
- Mode 5 (Straps B, C, E, H): Identifies after a transmission, but only if the keying input has been seized for a minimum of 4 minutes; no timeout function.

U7A and U7B D-type flip-flops act as latches, storing the state of the counter outputs for control of the identifier and the PTT line. When strap G is inserted, U7B Q output provides the timeout function via the U8C two-input NOR gate. Strap H is used when timeout is not required, relegating U8C to the function of an inverter for the keyed output of U5A.

The U7B $\overline{Q}$ output is used (1) to disable the ID cycle on timeout (option 3), (2) to provide an ID after each transmission (option 4), or (3) to provide an ID after 4 minutes (option 5), by clocking the D (data) input of U7A.

U7A's Q output is tied to the base of Q2, turning on +5 volts to power the PROM during ID, and to the base of Q3, keying the PTT line while the ID is being sent. The $\overline{Q}$ output controls the ID counter, starting the address count, and stopping it when reset occurs via U2D/U8D. Time-delay capacitor C1, 0.1 uF, should be equipped when options 4 or 5 are used.

When the U5A input is unkeyed, the input(s) of U8C go from low to high, removing the Q3/Q4 ground from the PTT output. The same change of state resets the U6 timer counter and the U7B timeout latch and stops the U5 timer clock.

Voltage Regulator Circuit

U1 is a ½-Ampere, 5-volt regulator chip. Heat-sinking of the package is not neces-

sary since the standing drain of the CMOS circuitry is very low, about 8 mA, and the heavier load of the PROM is short term since it is turned off when not required. This feature allows use of the timer/identifier even with low-power-drain repeaters operating from solar cells, batteries, etc. The output of the regulator is set at 5.2 volts by bringing the common lead slightly above ground with a 27-Ohm resistor. This offsets the voltage drop of about 0.2 volts through the PROM switch and, although not strictly necessary, was added because of the simplicity of doing so. The remainder of the circuit runs on the full 5.2-volt output. The input to the board can be anything in the range of 7 to 20 volts positive.

Optional Message Switch

This feature permits messages up to 512 bits in length to be sent by switching the PROM output to an alternative track after the first 256 bits have been transmitted. The address scan of the counter is recycled for the second track. The switch is mounted on a piggyback board over the main PC board and may be made of perfboard or any other suitable material. A PC board is not really necessary because of the simplicity of the circuit; six connections to the main board are required.

A CD4016 quad analog switch, of which three sections are used, is the base of the message switch. The MSG1 and MSG2 outputs of the PROM (or any two as selected) are routed through switches 1 and 2. Switch 1 is normally closed via a high on U9-13 from the +5-volt line through 100k. Switches 2 and 3 are open because of a low condition on U9-5 and U9-6. MSG1 is routed to the output.

When a count of 256 is reached, U3-1 goes high, turning on switches 2 and 3. MSG2 is now routed to the output. The closure of switch 3 to ground pulls the switch 1 control line low, removing MSG1 from the output. The address lines to the PROM recycle through all the 256 addresses or less, depending on the reset strapping, sending the second portion of the message. The reset-strapping options for messages over 256 bits long are:

- maximum 320 bits: strap to output pins 1 and 14.
- maximum 384 bits: strap to pins 1 and 15.
- maximum 512 bits: strap to pin 2.

The circuit could presumably be extended on the same principle for message lengths up to the full 1024-bit capacity of the PROM; however, few applications would require messages of this length. The average repeater ID requires considerably less than 256 bits.

Programming Considerations

The circuit as designed uses tri-state 256×4 PROMs such as the TI 24S10, Signectics 82S129, National 74S287, or their equivalents. This avoids the use of external pull-up resistors required with open-collector-output versions. The TI 24S10, which we used, requires that you burn those bits which are zeros in the message; that is, you burn the spaces and skip the dots and dashes. Other chips may require the opposite condition to this and it is best that you check the data sheet for the one you are using before proceeding to program it.

A delay of three or four bits should be programmed as spaces at the beginning of the message to allow the PROM voltage and the counter to stabilize, avoiding missing bits in the output. You will have to bum spaces from the last bit of the message to 1 bit beyond the reset point selected (at least with the TI chip).

To ease the construction work and programming, the authors are offering as a package a double-sided, plated-through circuit board plus a PROM programmed with the message of your choice, for $10.00. If you have any queries on the circuit, we would be glad to try to answer them as best we can. An SASE (US postage OK) would, as always, be appreciated. ■

Quick Qwip Conversion Fax

Seeing is believing. A few dollars and a weekend will turn this surplus unit into a reasonable facsimile.

A relatively new piece of fax gear has reached the surplus market in large numbers. The Qwip® 1000 is a solid-state send/receive unit manufactured in the mid to late 1970s. Circuitry is virtually all IC chips, and common ones at that. These model 1000 machines are available currently because they were recently replaced with the newer and more sophisticated model 1200. The units look similar, but the electrical circuitry is vastly different.

The scope of this article is introductory. These units are certainly worthy of conversion for fax work, and since it is likely that the newer models will also show up as surplus in the near future, I'll try to cover the differences as well as the operational characteristics.

The Qwip units were designed originally for business office use and are easy to operate. The basic design includes a telephone handset cradle, called a coupler, for sending or receiving over long-distance telephone lines. In this way, contracts, manuals, and other documents may be transmitted immediately from one business office to another. At the sending unit, a document is placed on the drum and the selector switch over the drum is placed in the send mode. Each machine has a two-position send switch. In normal use, compatible with most other fax machines, the 6-minute send position is used. The alternate position is for a 4-minute send duration and should be used only with other Qwip machines set for that duration. As soon as the send button is pressed, the unit begins transmitting its image to another unit. That's all there is to sending.

On the receive end, the operator places an 8″×10″ piece of fax paper on the drum and sets the selector switch to receive. A one-way clutch knob located on the right side of the roller drum opens a lock rail on the drum. After the paper edge is placed in the roller clamp rail, the clamp is closed and the paper is secured to the drum. The other edge of the paper remains free, but may be taped down if desired. By prearrangement, a 6-minute or 4-minute speed is then selected to match that of the sending unit. Then the telephone handset is placed on the cradle.

In the receive mode, the drum and stylus do not operate until the unit senses the send signal of 2400 Hz. A 566 tone decoder then activates the drum circuit. The receive unit, once started, will continue to print until the read/write assembly traverses the drum, the phone line is cut off, or the unit is switched off.

Qwip units will not send or receive if the drum com-

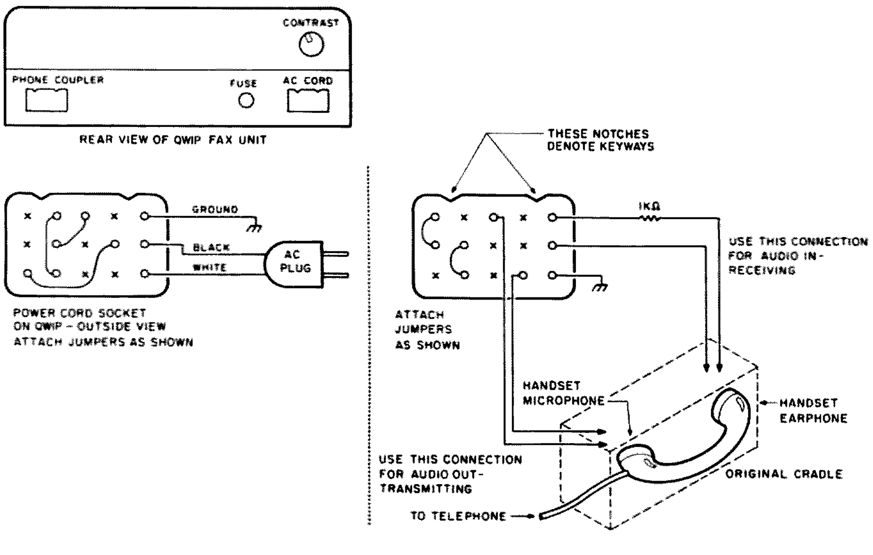

Fig. 1. Wiring connections for Qwip 1000/1200.

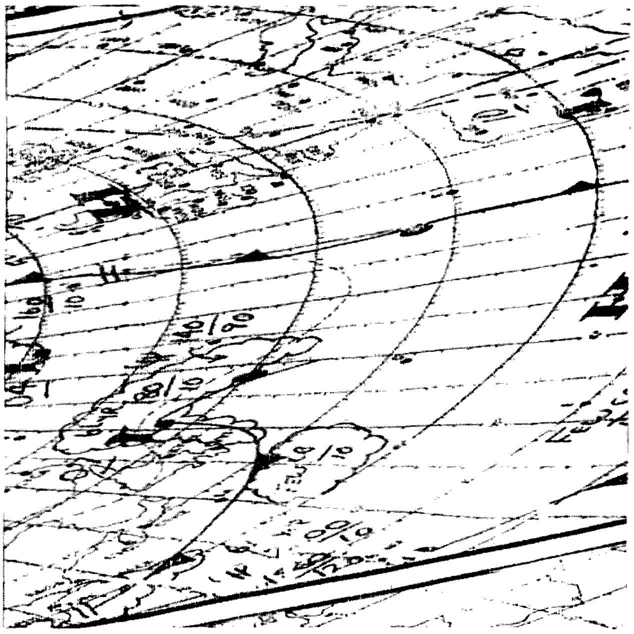
partment lid is left open. A reed switch activated by a magnet in the lid handle will idle the drum and circuits. At the end of normal operation, or in case of failure of some sort, a 555 timer chip buzzer will sound.

So much for normal operation. There are a couple of other minor controls and they are self-explanatory. As with any other piece of surplus, the Qwip units do not come complete with peripherals, namely, the ac patch cord and phone cradle, but for amateur radio or weather fax use this is no disadvantage.

The best way to ensure you'll get a working Qwip from surplus is to buy several and use 2 or 3 bad ones to make one good one. Reasons: For one thing, manuals and schematics are almost nonexistent. Also, many units have had holes drilled through crucial parts, wrecking each unit from a repair standpoint. Fortunately, the folks who drilled these never hit the same spot twice from unit to unit. In my case, I bought 2 units; one had holes in the circuit board, but the other only had a wrecked wiring harness. With one intact board and one good harness I soon had a like-new unit. I should mention that these units will require a good cleaning before they are fit to use.

The Qwip 1000s now available were brought in for repair but the dealers just gave out new 1200s in exchange. Any Qwip 1000 is bound to need repair. Most Qwips are sold with complaint cards still attached. One of mine read "noisy motor." The problem turned out to be a bent fan blade, remedied with an appropriate twist. A damaged wiring harness was the only other problem I uncovered. I recommend buying several units though, for another reason: The plug and socket connectors for the ac patch cord and phone cradle are interchangeable, and by robbing several Qwip units you can get a complete set of male/female connectors. As small as the Qwip units are, there is room to mount other plugs, if needed.

Fig. 1 shows the necessary plug/socket wiring. To make a Qwip unit workable, the jumpers must be added for normal use. (The view is of the outside of the Qwip.) This connection diagram will work for any model 1000 or 1200. The contacts identified as circles are used. The X contacts are unused. In tracing out the wiring harness to these sockets, you may find wires that go to these X pins, but do nothing. They may be removed or ignored.



A fax copy on HF (8.08 MHz) with bfo tuned to 2400 Hz. 120 rpm; a Qwip 1000 conversion.

Mechanical operation of the Qwip units is limited and there's not much to go wrong. The end bearings of the drum shaft should be inspected, lubricated, and if necessary, replaced. The stylus relay on top of the drum operates a copper stylus arm which holds a steel wire. Should the wire get broken or used up, it is very easy to repair. Just

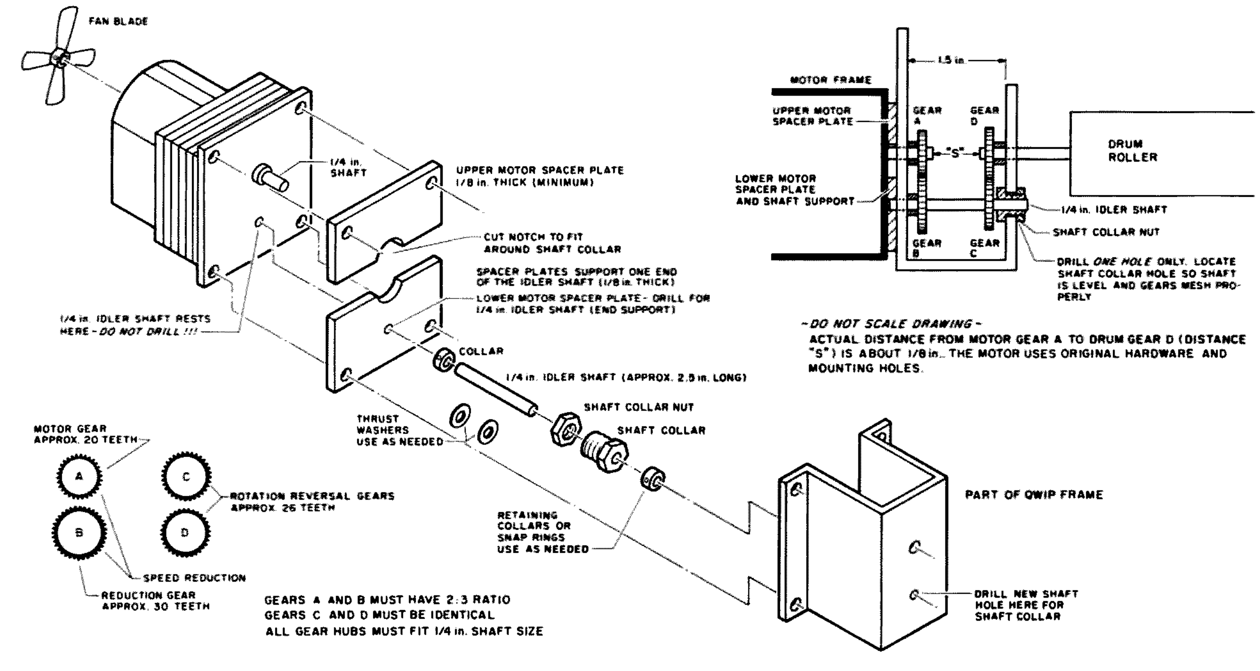


Fig. 2. Details for the 120-rpm speed conversion for the Qwip 1000.

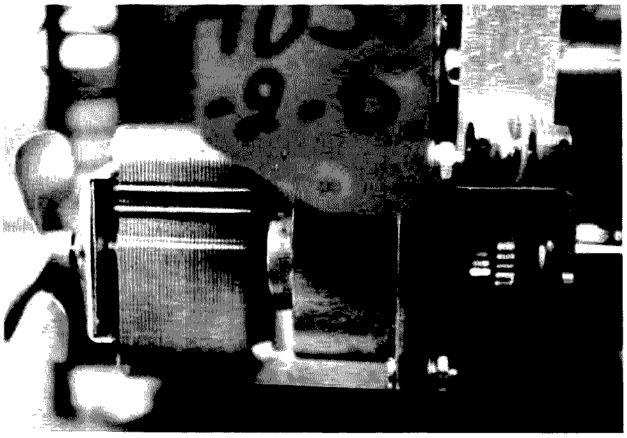


Top view of the unconverted Qwip 1000 showing the original shaft coupler in place. Note the bent fan blade.

Top view of the converted Qwip 1000 and the original coupler that was removed. The motor will mount either right side up or, as here, inverted.

remove the copper contact arm and solder a bristle from a wire brush to it. Replace the copper arm and manually operate the relay to check for good contact with the drum. The steel wire should not contact the drum when the relay is deenergized.

The drum speed of the standard Qwip unit is 180 rpm, which is compatible with many other office-style fax machines. This speed is common on amateur radio frequencies, and once a Qwip unit is working properly it should be easy to interface it with radio gear for sending or receiving. Qwip paper is good for letters, callsigns, etc., but I recommend photocopy paper (Xerox®, etc.) for photographs.

An actual weather satellite image taken from a converted Qwip. Lake Winnipeg is in the upper left-hand corner.

The Qwip 1000 is mechanically similar to the 1200, but electrically they have little in common. The Qwip 1000 motor, for example, is a basic ac-synchronous mechanical motor, bulky and heavier than its 1200 counterpart, and it lends itself easily to speed conversion for weather work. By contrast, the motor in the 1200 series is a dc-driven servo-motor no larger than a C-size battery cell. Its speed is crystal-controlled and would be difficult to adjust without a technical manual. The Qwip crystal frequency for this motor is 20 kHz. The 1200 chassis sports a separate circuit board to drive the motor, consisting mostly of 7400-series circuit chips. The 1200 power transformer is bigger, no doubt to accommodate the added circuit board. In general, the wiring layout is cleaner on the 1200, and the pots contain more glue to secure their positions.

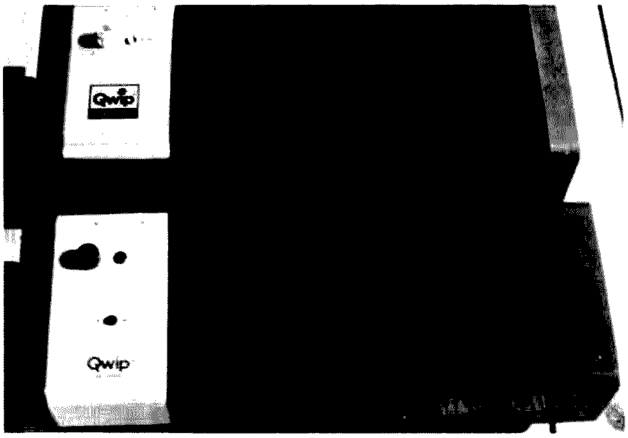
The main circuit boards look similar in both the 1000 and 1200, but the parts layouts change once you get past the power-supply diodes. None of the adjustment pots is captioned or identified. The few pots I could decipher were not located near the chip they control. The 1200 also has a switch labeled Compatibility Selector. For this, the circuit board contains an extra relay. In operation, the switch makes an LED flash for compatibility with a Qwip 1000 or burn steadily when it is to be used with another 1200.

For power, the Qwips produce two voltage levels. One is plus and minus 15 volts to drive the op amps, TTL chips (5 volts), and relays (12 volts). The other level is approximately 200–300 V dc for the stylus to burn the paper.

The one factor responsible for the Qwip 1000's early introduction to the surplus market had to be its mechanical design and the flaws therein. The Qwip 1000 used the same low-cost plastic material throughout its mainframe. This plastic held up poorly and suffered mechanical stress resulting in many cracks throughout the main subassembly—right where the drum roller functions, to be exact. Thus, the model 1000 series prob-

ably has flaws in the worst possible places for amateur fax work. Nor does the plastic material mend easily with glue—another reason for purchasing more than one.

The 1200 overcame this problem by changing the subframe material to a much stouter fiberglass. Along with an improved electrical design, the 1200 hosts a lighter-weight roller. Its bearings have less drag. The Qwip 1000 used a slotted roller with a cutting blade mounted in the read/write head. The 1200 model uses a smoother roller and no cutter, indicating that an improved phasing circuit has been added. Neither type of roller is made of electrically-conductive material. Grounding is achieved through a set of mechanical fingers which rest against the roller and are located at the very bottom of the machine. Partial conductivity can be made through the retaining clamp built into the drum roller, but this is not a good conductive path for the stylus. The 1200 is not a copper/steel assembly as used in the 1000 series; the 1200 stylus is a wire-filled fiber.



The Qwip 1000 (top) and the nearly-identical Qwip 1200.

Considering that the Qwip units cost several hundred dollars new and are going for fifteen to thirty now, the mechanical drive system alone is worth the asking price. The circuit boards are a bonanza for ICs and tantalum capacitors. Parts and component values are completely standard.

Like most fax machines made commercially, the Qwip machines easily lend themselves to modification. Fig. 2 shows a mechanical gear-reduction assembly that can be used for changing the drum speed to 120 rpm for weather fax operation. Although the gears are shown spread out, the actual assembly fits into an area narrower than a Band-Aid™ box. The drawing gives location details of the parts needed. Using the arrangement pictured there, the conversion requires only one *very carefully* placed hole to be drilled in the Qwip sub-chassis just under the drum-roller shaft hole. (This is another good reason to own more than one Qwip—practice.) Originally, the motor shaft was directly coupled to the drum shaft and this coupling can be restored if 180-rpm operation is ever desired again. The original motor mounting holes are preserved; the motor is just moved back a wee bit. This conversion requires some degree of care and patience, but is not difficult. The four gears necessary are all that need to be purchased. The other parts are fashioned from scrap.

About the gears: I have labeled them gears A, B, C, and D. A and B do the speed reduction but leave the quarter-inch shaft turning the wrong direction. Gears C and D are for direction reversal. They wouldn't be necessary except that the drum-roller shaft rides on a one-way bearing located at the right side of the Qwip subframe. As it turns out, the gears needed fit just fine with little effort.

Gear A is a Boston gear #H3220 and is the only gear that comes with a ¼-inch hub diameter. All others require hub bushings and they are reasonably priced. Gear B is a Boston gear #H3230. Gears C and D are identical. You might try Boston #3226, although you may need to go up or down one size in order to reach a proper fit. I did the whole conversion in one day, making it up as I went along. Once finished, conversion to or from 180 rpm takes just a few minutes.

In HF work where the transmit tone is 400 Hz, try using a bfo pitch tuned to 2400 Hz to activate the drum-rotation circuit. The bfo tone has almost no effect on picture quality. Signals are generally available on 8,080 and 10,865 MHz and produce good results on a Qwip.

The Qwip units will print from a whisper. It is all too easy to overdrive the input to the point where the drum will stop turning because the tone decoder is overloaded. A 100k trimpot is recommended for the input line. It should cure most troubles, although internal adjustments may also be required.

Judging by the many applications for which the Qwip components may be used and the very low price tag, the Qwip 1000 or 1200 could easily rank with the ARC-5 units as the surplus buys of the century. ■

No-Etch Circuit Boards

Produce quality PCs with N6JH's cut-and-pry technique.

One of the more persistently recurring problems with home-brew projects is making printed circuit boards. Amateurs have used many approaches to this dilemma, and numerous articles describe schemes ranging from the most sophisticated photographic and etching techniques to the crudest methods of drawing the traces directly on a board. But one of the more overlooked ways to make prototype boards is to bypass entirely the printing and etching and directly cut the conductive traces by hand.

Many of the boards used by amateurs, especially for high-frequency work, are simple. They have few traces, the trace widths are relatively large, the traces are mainly or entirely on one side of the board, and the required tolerances are not especially critical. Such designs are easily and quickly produced by a direct method which requires only a sharp knife and a soldering iron. This article describes how to make such boards and illustrates the process with a hand-cut rf board.

This process involves four basic steps: preparing the artwork used to guide the cutting, scoring the traces, peeling away undesired copper, and building the final circuit. Each of these steps will be described in detail.

Preparing the Artwork

The first step in hand-cutting a board is to decide where to cut. The best approach is to prepare a drawing of the desired circuit traces which can be used to guide the knife. This can be done a number of ways. If, for example, the circuit to be built is described in a magazine article which includes a printed-circuit-board pattern, this pattern itself, or a photocopy, can be used. Alternatively, a design can be drawn on paper and used as the guide.

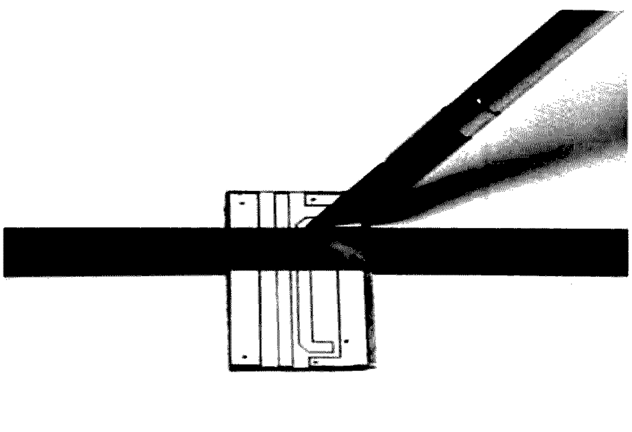

Photo A. The paper artwork has been cemented to the copper-clad circuit-board stock, and a steel ruler is used to guide the razor knife along straight lines to score the copper.

If the design is to be transferred from a magazine page, it is best to make a photocopy. This not only preserves the original in case more than one board is needed, but also it gives better results because the paper used in magazines is usually too thin and slick, while a sheet of photocopier paper will be less likely to wrinkle during cutting.

If you are making your own drawing, it is best to make it larger than final size to reduce drafting tolerance errors. This, of course, is the technique used in the normal photographic production of printed circuit boards, where the artwork is typically two or four times as large as the final board. In photographic work, a large studio camera is used to make the reduction, which produces a very accurate reduced image. This accuracy is not needed for hand-cut boards, so we can use a simpler and less expensive technique.

The key to a simpler and cheaper reduction lies in the widespread availability of photocopiers which can reduce the size of an original document. This feature is designed to make it possible to print large documents on small paper and was never intended for the production of accurate artwork, but it serves well enough for our purposes.

Photocopiers with reduction capability typically reduce by at least two different factors. The two most common appear to be 77% and 64%. If original artwork is reduced by 77% and the resultant copy is itself further reduced by 64%, the final copy is smaller by a factor of .77 × .64 = .493. Thus, if the original was twice the desired final size, the second copy will be the desired size with a deviation of only a few percent.

No matter which approach is used to produce the artwork, the next step is to cut it out and paste it directly onto the circuit board's copper surface. One of the better glues for this seems to be regular rubber cement. This glue quickly sticks the paper to the copper, the artwork can be smoothed to remove air bubbles, and the paper is firmly held during cutting. After cutting, the paper is easily peeled away; the rubber cement leaves no residue to interfere with soldering.

Up until now the assump-

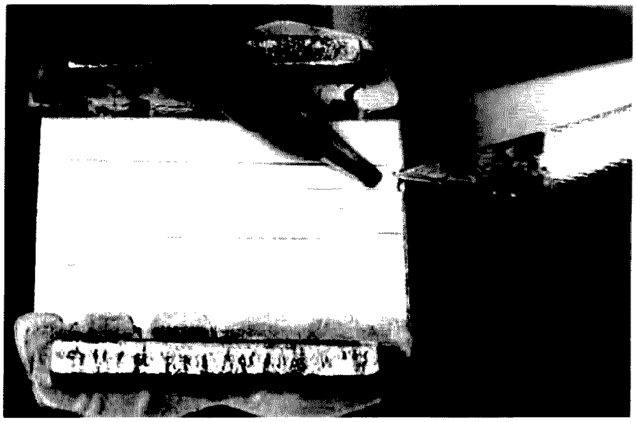

Photo B. The copper to be removed is first lifted at one end by simultaneously heating the area and sliding a knife point under the piece.

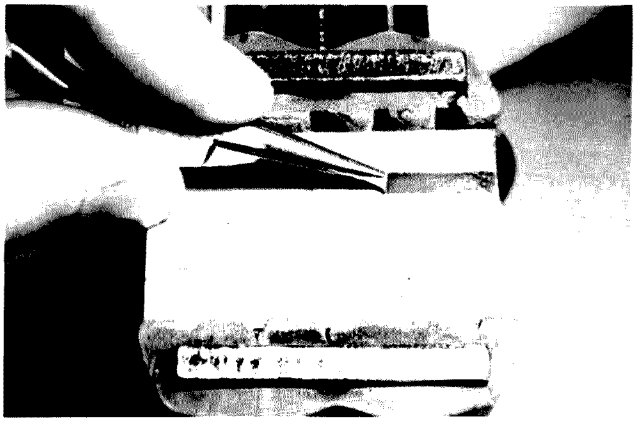

Photo C. After the edge of the copper strip is lifted a bit, grasp it with a pair of needle-nose pliers and smoothly peel away the strip.

tion has been that the circuit traces are found on only one side of the board, and that the other side is either blank (a single-sided board) or is covered with an unbroken ground plane (as is common in rf microstrip circuits). If traces must be cut on both sides, some way to align the two sides is needed. One way to do this is to drill a few alignment holes as aids in lining up the two sides. Other than this, production of a two-sided circuit is the same as a single-sided board.

Cutting the Traces

Once the paper pattern has been glued to the surface of the board, the next step is to score the edges of the traces. This step requires a sharp knife, a steel ruler, and a bit of care.

The best knife to use for cutting the traces is a hobbyist's razor-edge knife. This knife should have a razor-sharp blade stiff enough so that moderate pressure can be applied to score the copper. It should also have a handle—don't try to cut with a bare razor blade or the results could be gory.

It is at this point that you realize the advantages of circuit traces which are straight lines. The steel ruler serves as a guide for the knife blade when cutting straight lines and provides maximum accuracy. Curves can be cut, but they must be cut freehand, or else some type of cutting jig must be found. A drafting "French curve" would probably serve. No matter what type of guide is used, it seems best to apply moderate pressure and to go over the line to be cut several times. If cutting freehand, make the first cut for accuracy and then go over that scored line several times. The object is not necessarily to cut all the way through the copper, but rather to produce a heavy score line along which the undesired copper can be peeled away.

Go over all of the lines to be cut and check to see that none has been missed; once the paper has been peeled away, it is harder to add missed traces. Next, use a center punch or awl to dimple the copper at all the locations where holes are to be drilled.

Photo A shows the first steps of the cutting process. A simple rf board, in this case a microstrip directional coupler for the 1296-MHz band, has its photocopied artwork glued to the copper. The knife is guided along the lines by the ruler to accurately score the traces.

Now strip off the paper artwork and remove any of the rubber cement which remains on the board. A rubber pencil eraser works well to roll any remaining bits of glue off the copper. Inspect the board to see that none of the lines or hole guides has been forgotten.

Peeling Off Unneeded Copper

The next step involves removing the undesired areas of copper. This is easily done with the point of the razor knife and the aid of some heat from a soldering iron.

Printed-circuit-board material has a surface layer of copper glued to a fiberglass base material. If the copper is heated a bit, the glue's grip is greatly reduced, as anyone who has ever "lifted" a printed circuit pad has discovered. This tendency can be used to our advantage, though.

Apply a bit of heat to the edge of one of the copper pieces to be removed, and at the same time gently slide the point of the knife under the edge of the copper. The copper will lift easily in the heated area. Lift a large enough piece of copper so that a pair of needle-nose pliers can get a grip. Photo B shows the edge of a trace being lifted this way.

Then, without using more heat, a strip of copper can be gently pulled away from the board, as shown in Photo C. With some care, a large piece of copper can be stripped away. Usually the stripped piece will break when a scored line is reached. At this point, use the knife and soldering iron to again lift a corner and continue with the pliers.

Sometimes the most difficult part of stripping away the undesired copper is to avoid removing circuit traces. In the effort to carefully remove small areas of copper, it is easy to lose sight of the larger picture and remove desired pieces as well. To avoid this, color in the areas to be saved with a felt-tip marker before peeling.

After all of the excess copper areas have been removed, drill all of the holes in the board using the dimples as drill-centering guides. Clean the board with rosin flux remover, and it is ready for assembly.

Summary

Prototype circuit boards can be produced quickly by using these simple techniques. With practice, nearly any board can be cut by hand, not only simple rf boards, but more intricate analog and digital circuitry as well. The results, while not up to the standards of printed circuit boards, are nevertheless satisfactory for many amateur projects; the low cost and rapidity of the method are unbeatable! ■

Disco Duckie?

Try some dirt-cheap headphones for your HT.

Carl Peterson N6CSI
PO Box 4432
Chico CA 95927

If you are supplying communications for a parade or other event with a noisy background, a set of lightweight headphones is an asset, especially if you are tired of holding the speaker mike (SMC-24) up to your ear on a cold winter day. Borrow the stereo headphones from a Walkman-type radio and make the adapter in Fig. 1. If the headphone plug accidentally disconnects, it will automatically switch back to the speaker mike. Its resistance is 9.4 Ohms, and that of the the headphones used was 16.8 Ohms (in parallel). All parts were obtained from the local Radio Shack.■

Ntty Grtty RTTY

Tomorrow, to Morrow, is too late. Build this easy Timex/Sinclair interface today and be on the air tonight.

Many would-be RTTY enthusiasts no doubt are dismayed when they discover the potential high cost of quality RTTY gear. Although many inexpensive computers are on the market today, the cost of the interface and software usually far exceeds the price of the computer itself.

The Timex/Sinclair (T/S) computer is a very low cost, self-contained system. With an ordinary cassette recorder, a black-and-white television, and the transceiver interface system and software described in this article, you can have a complete RTTY terminal:

1) You will be able to transmit and receive Baudot code at 60, 66, 75, and 100 words per minute with a 170-Hz or 850-Hz shift, and

2) Receive 425-Hz shift commercial Baudot code broadcasts at all speeds listed above.

3) It will have a simple transmit/receive control with an optoisolated T/R switch,

4) LED indicators for high and low received tones, with carrier detect, for simple tuning,

5) 850-Hz and 170-Hz six-pole active bandpass filters to combat QRM, and

6) An audio frequency-shift keying (FSK) monitor during transmit to ensure that the typed character is sent.

7) Everything is powered by the T/S computer power supply.

At today's prices, the computer and interface circuit together will cost about $100.

The software and a full-display screen will fit into the 2K of random-access memory (RAM) provided with the Timex/Sinclair TS-1000 with no modifications required to the com-

Photo A. The Timex/Sinclair computer, along with a TV, cassette recorder, interface unit, and a transceiver, make up the complete RTTY station.

Photo B. The interface unit is versatile enough for the various amateur and commercial RTTY code-reception schemes, as well as 170-Hz and 850-Hz transmission using standard mark and space frequencies. Note the toroid rf chokes on the computer power and video cables.

puter itself. My software went into a Sinclair ZX81 which I converted to 2K of RAM through a simple chip substitution described in this article.

I have learned to touch-type on the Sinclair's membrane keyboard and seem to do about 30 wpm. For heavy use, you will probably want to attach one of the after-market full-stroke keyboards.[1]

If you are unfamiliar with the mechanics of RTTY, you might want to read the introductory article by W9IF[2] for an excellent explanation of the basics.

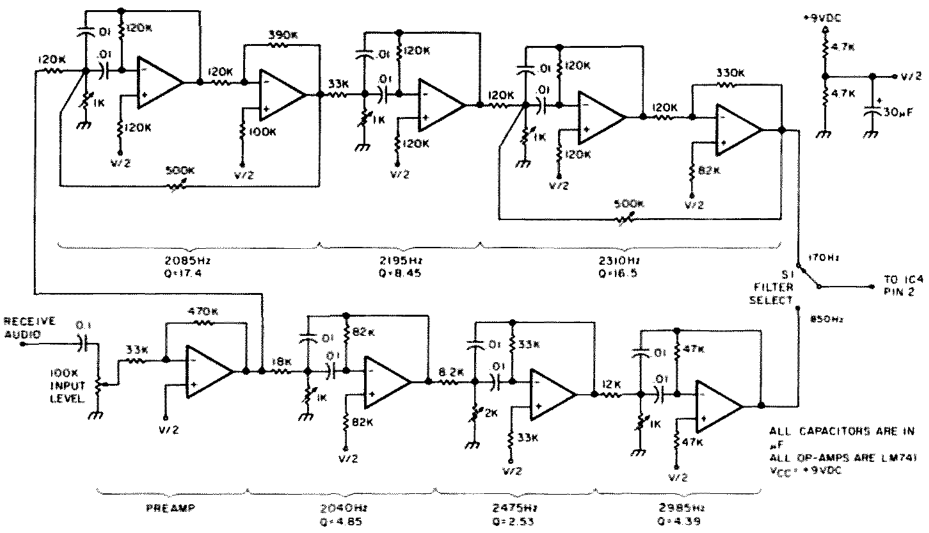

Fig. 1. Schematic of the 170-Hz and 850-Hz active bandpass filters.

FSK Receiver

The receiver section of the RTTY interface is built around a high-quality filter section followed by a phase-locked-loop (PLL) tone-decoder chip. Low-level audio tones are amplified by the 741 preamp (Fig. 1) and then processed by selectable six-pole bandpass filters for either 170-Hz or 850-Hz shifts. The filters are based upon a design by K2OAW[3] and go a long way toward eliminating nearby QRM. Be sure to use polystyrene or mylar™ capacitors on the op amps for temperature stability. K2OAW also recommends the use of single 741 op-amp packages rather than the dual or quad types. The passband of each filter stage is calculated by dividing the center frequency by

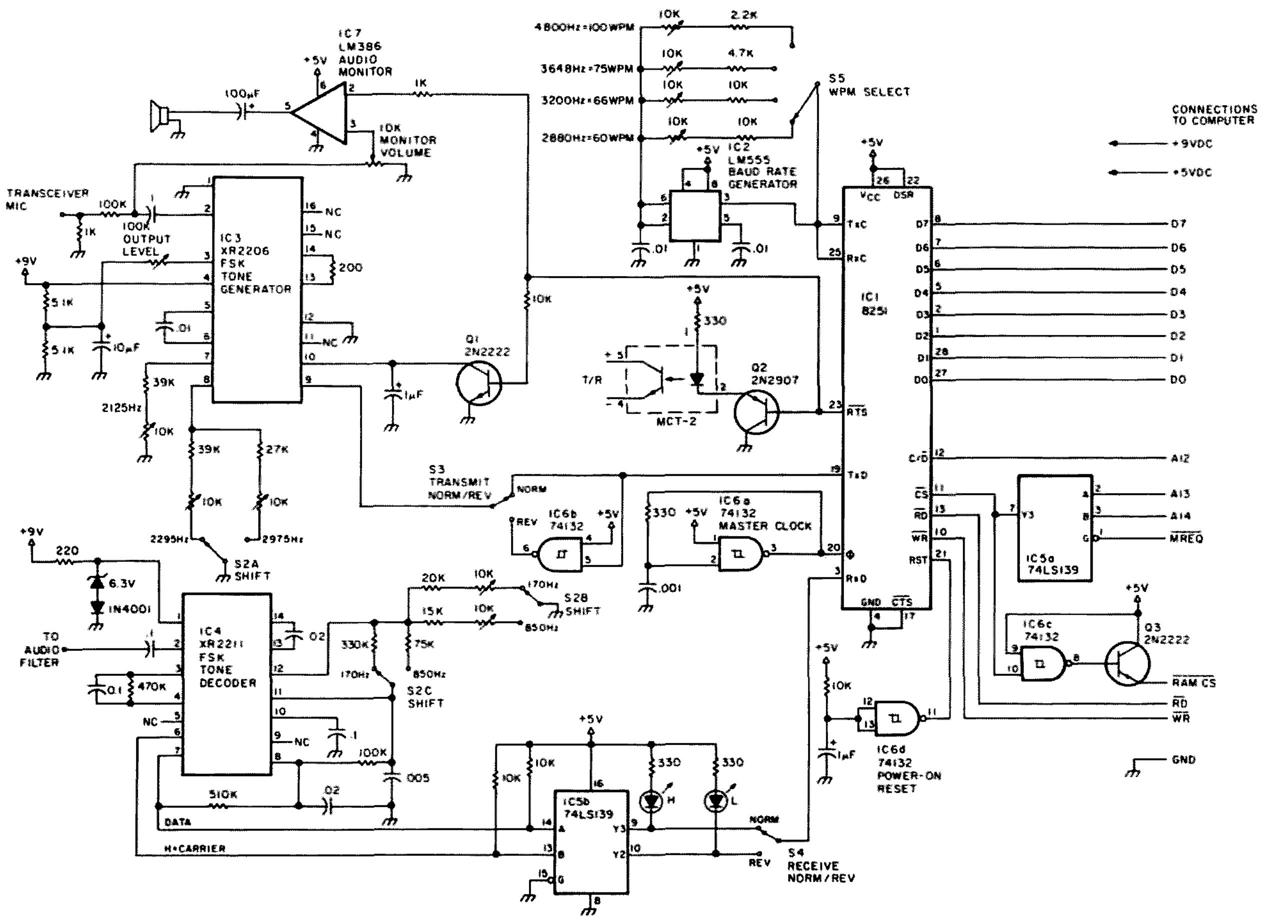

Fig. 2. Schematic of the computer interface circuit, along with the RTTY tone encoders and decoders.

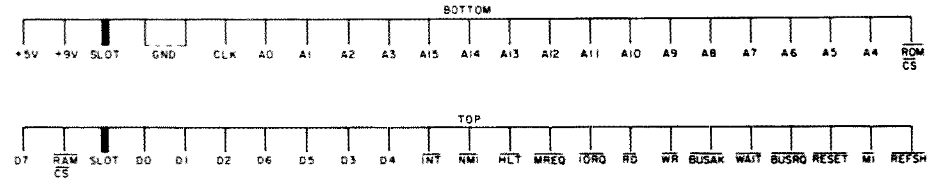

Fig. 3. Timex/Sinclair computer rear-connector pinout diagram. This diagram applies to both the ZX81 and TS-1000.

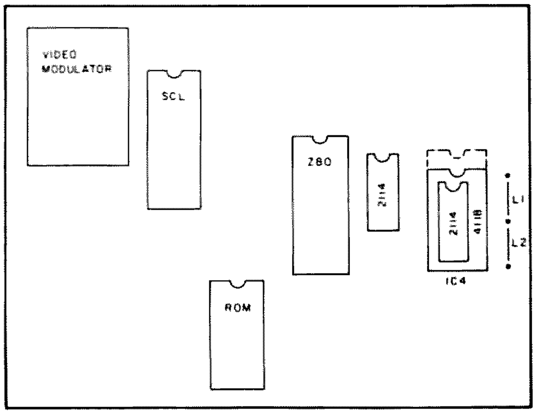

Fig. 4. ZX81 computer circuit-board integrated-circuit layout. To convert the computer RAM to 2K, remove the 2114/4118 chip(s) and replace with a 2016 or 6116 chip at location IC4. Ensure jumper L1 is open, and connect a wire across L2. Parts are available from Jameco Electronics, 1355 Shoreway Road, Belmont CA 94002.

the Q, both of which are given in Fig. 1 for each filter stage. If you have the proper i-f filter in your receiver, you can eliminate the audio bandpass filters, but since these are tailor-made for RTTY, you may want to include them anyway.

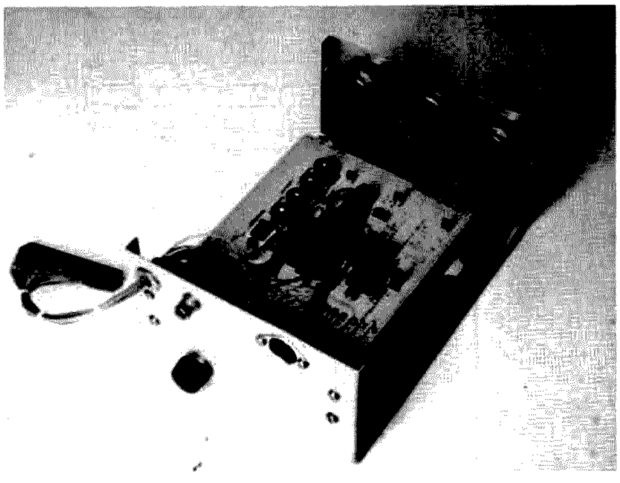

Photo C. The interface circuit was built on proto boards available at Radio Shack. The top board (shown) contains the digital portion of the circuit while the lower board contains the filters and tone generator and decoder chips. No printed circuit board is available. The DIN socket is used for the cable to the mike jack on the transceiver, and a standard phono patch cord connects receiver audio to the phono jack. Both of these cables should also have toroid chokes attached to prevent RFI. The knob on the rear panel controls the audio-monitor volume.

The appropriate filter is selected by S1, which sends the tones to the input of the XR-2211 tone decoder (Fig. 2).[4,6] S2b and S2c select 170-Hz shift tones for HF amateur RTTY or 850-Hz shift tones for both VHF amateur and 425-Hz shift commercial signals. The zener regulator on pin 1 of IC4 eliminates ripple from the T/S computer's 9-V supply for reliable decoding.

The carrier detect and data lines of IC4 are sent to IC5b, which provides normal and reverse logic data through S4. At this point, the frequency-shifted audio has been converted to TTL-compatible logic levels. The two LEDs on the output pins of IC5b indicate high and low tone frequencies present at the input of the decoder. If proper audio tones are not present at the input to IC4, the carrier detect line is pulled low and both LEDs are extinguished. This system takes the guesswork out of tuning the RTTY station properly.

8251 Programmable Communications Interface

The Baudot-encoded serial data is now sent to pin 3 of IC1, an Intel programmable communications interface chip.[7] This device assembles a complete 5-bit character from the serial data at pin 3 and signals the Z80 central-processor unit (CPU) of the T/S computer during the next status read operation. The CPU then performs a data read and accepts a complete character to be decoded and dis-

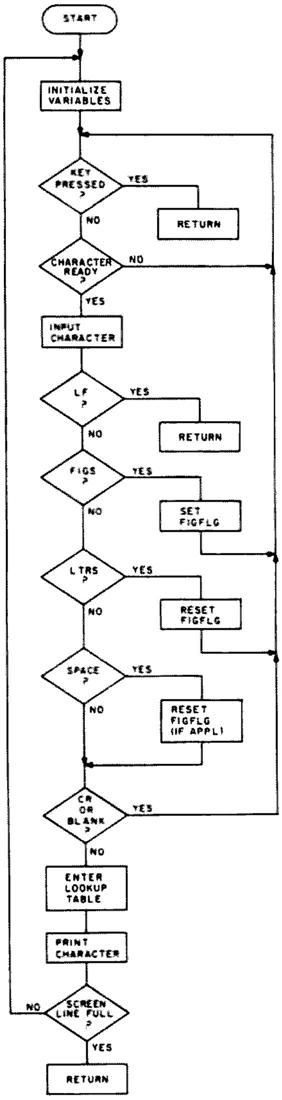

Fig. 5. Flowchart for the receive portion of the assembly code.

played. The T/S computer cannot perform the serial-to-parallel character conversion itself, in real time at least, because the majority of its computation time is used to generate the display and a portion of nearly every character would therefore be lost Of course, the 8251 chip solves this problem neatly. For more information on the 8251, you should refer to the *Intel Microcomputer Data Book*.

IC6a provides a master clock of about 1 MHz for the 8251, and IC2 is an astable multivibrator acting

Fig. 6. Receive assembly-code listing.

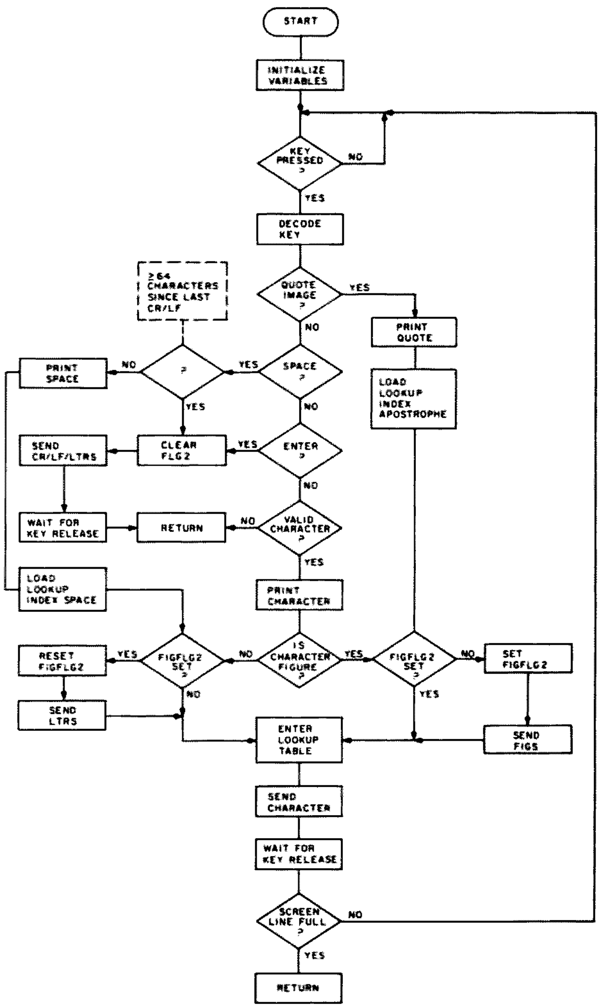

Fig. 7. Flowchart for the transmit portion of the assembly code.

as a baud-rate generator for 60-wpm (45-baud), 66-wpm (50-baud), 75-wpm (57-baud), and 100-wpm (75-baud) data rates. A power-on reset pulse is provided by IC6d. The 8251 chip is selected through IC5a; during this time the internal T/S computer memory is disabled by IC6c and Q3.

FSK Generator

When transmission begins, the 8251 is given a command by the CPU and pin 23 is driven low, causing the optoisolated T/R switch to close and the audio monitor (IC7) to come on. Also, the XR-2206 tone generator (IC3) is activated when Q1 cuts off. The tone generator and monitor do not operate during receive to avoid interference to the tone decoder.

When a valid Baudot character is entered on the computer's keyboard, this character is loaded into the 8251 which clocks the data serially out of pin 19, through the normal/reverse switch, S3, and to pin 9 of IC3. This function-generator chip produces a 2125-Hz mark tone when pin 9 is low and a selectable 2295- or 2975-Hz space tone when pin 9 is high.[5,6] The mark and space tones are inverted when S3 is set to reverse. The selector switch, S2a, is ganged with S2b and S2c to ensure identical receive and transmit shifts.

Hardware Construction

Be sure to build the interface circuit in a metal box (Photo B), and keep the wires to the T/S computer short or you won't believe the RFI you'll get. A 46-pin .100-inch-spaced edge-card connector for the T/S computer back-panel can be made by cutting down a Radio Shack 276-1545. The required computer signals can be tapped off this connector by referring to Fig. 3.

Note the toroid-core chokes on the power and display wires to the computer and on the transmit and receive lines to the rig. These chokes help keep computer noise out of the rig and transmit rf out of the computer. With my system as shown, computer noise in the receiver is virtually nil, and 100 Watts of continuous RTTY-transmit power will not affect computer operation. If you have RFI trouble, try changing equipment positions, ground connections, antenna location (if possible), and the number of turns of wire on the toroid chokes.

The adjustment procedure is straightforward. Set each filter pot (Fig. 1) for the desired response; the 1k and 2k pots adjust center frequency and the 500k pots on the 2085-Hz and 2310-Hz sections adjust the Q. The single-stage filter elements all have their Q fixed at the value shown on the schematic. Set the pots on the 555 (IC2) and the XR-2206 (IC3) for the frequencies shown (Fig. 2). You can activate the XR-2206 by temporarily grounding the base of Q1. Now feed the transceiver mike signal from IC3 to the input of IC4 and adjust the two pots on S2b for reliable switching while using the LEDs as indicators. As an alternative, an audio generator will allow more precise alignment of IC4.

The two pots on S2b should be set so that the data (IC4 pin 7) changes logic level when the input tone frequency is about halfway between the respective mark and space frequencies for the 170-Hz and 850-Hz shifts. Also, ensure that the carrier detect (IC4 pin 6) is pulled high for the mark and space input tones.

Assemble the jumper cables between the interface box and your rig. I used a

DIN socket on the box and a 2-conductor shielded cable between the box and my transceiver mike jack. Be sure to add the toroid choke before soldering the DIN plug onto the interface box end of the cable. A common stereo patch cord with phono plugs on each end carries the receive audio from the rig to the interface box.

ZX81 2K RAM Modification

If you intend to use the ZX81 computer in your RTTY system, you'll need to replace the 1K RAM chips with 2K of RAM to make room for the software and display requirements. (The TS-1000 already has 2K of RAM, so skip this section if you have one of these computers.)

Fig. 8. Transmit assembly-code listing.

First, peel off the four rubber feet on the bottom of the ZX81 and remove the five screws and the back panel. Remove the circuit-board screws and carefully turn the board over. Gently remove the keyboard cables from their sockets. Refer to Fig. 4 for chip placement, and remove both 2114 ICs or the single 4118 IC. Either memory configuration may be used in the ZX81. I recommend using de-soldering braid, and don't force anything; traces are easily broken. Remove the jumper wire at L1, if it exists.

Now solder a 2016 or 6116 2K × 8 RAM chip at position IC4. Notice that the circuit board has 28 holes in this position; use the *lower* 24 holes. Solder a jumper at L2 to connect address line A10 to the RAM chip, and reassemble the computer.

To check memory operation, type:

PRINT PEEK 16388
+ 256 * PEEK 16389

This should give a result of 18432 if the 2K of RAM is working properly.

The Software

Many of you probably have discovered that the T/S computer has a very slow Basic interpreter due, once again, to the large percentage of computation time required for the display. I designed the RTTY software to be somewhat of a hybrid: part Basic for convenience and part Z80 assembly code for speed.

Figs. 5–8 give listings and flowcharts for the receive and transmit portions of the software, both of which are written in assembly language. For the most part, these routines handle the Baudot-to-Sinclair code conversion and character display during receive, and the keyboard input, character display, and Sinclair-to-Baudot conversion during transmit.

Fig. 9 shows a listing of the assembly-stuffer program. Line 1 saves 199 bytes of space in RAM for the actual code and includes the Baudot-Sinclair and Sinclair-Baudot lookup tables. Line 2 contains all of the assembly code in Figs. 6 and 8 as one long string. Lines 3–7 convert this string into actual hexadecimal numbers, then stuff them into the memory reserved in line 1.

Enter this program exactly as shown in Fig. 9, then RUN it. When the run is complete, LIST the program and check that the decimal numeric sequences have been replaced with jumbled code and that the two lookup tables are still intact. The jumbled listing is the display read-only-memory (ROM) interpretation of the actual assembly code located there. Now DELETE all of the program *except* line 1, CLEAR the variables, and you are ready to enter the Basic part of the software.

The listing of Basic commands is shown in Fig. 10. Lines 10–80 will allow for an unshift-on-space routine in the assembly code for receive by POKEing appropriate commands into locations 40AFH and 40B0H (Fig. 6). If the unshift on space is not selected, NOPs are put into these two locations. Lines 90–100 software reset the 8251 chip, and lines 110–190 are the receive portion of the program. This routine sends the receive command to the 8251, scrolls the screen on each line feed (LF) or when 32 characters have been displayed, and monitors the keyboard for SHIFT T (CHR$ 221) for a jump to the transmit routine located at line 200 and beyond. This por-

Fig. 10. Listing of the Basic portion of the program. Line 1 is all that remains of the assembly stuffer, and lines 10–270 control the transmit and receive assembly program code.

tion of the program sends a transmit command to the 8251, scrolls the display, and monitors the keyboard for a SHIFT R (CHR$ 219) for a jump back to receive.

Now key in lines 10–270 and SAVE "RTTY" twice on cassette to ensure at least one good copy.

Assembling and Operating the RTTY Station

Be sure the power is off to the T/S computer before connecting (or disconnecting) the interface box. If you didn't key the connector to the slot in the T/S circuit board, be certain the connector is installed right side up. Connect the cassette recorder and TV monitor to the computer and attach the jumper cables between the interface box and your rig. Turn on the computer and receiver and follow the guidance in the Hardware Construction section (above) if you have RFI trouble.

Now LOAD and RUN the RTTY program. The unshift-on-space routine is a convenience during receive to prevent lockup in the FIGS mode if a LTRS command is missed; the system also will return to LTRS mode upon receiving a space. However, weather broadcasts consist of many strings of numbers separated by spaces, and transmission would be slowed considerably if a new FIGS command had to be sent after each space. Therefore, it would be a good idea to select unshift on space for everything except weather broadcasts.

Set your receiver to the RTTY mode, or adjust the i-f passband, to allow reception of the mark and space tones with minimum attenuation. For amateur reception on the HF bands, select the 170-Hz filter and shift, set 60 wpm, and find a RTTY signal. Your best bet will usually be just below 14100 kHz. Select normal on the NORMAL/REVERSE switches and advance the input-level pot while tuning around the RTTY station until the LEDs illuminate.

Now tune the receiver until the LEDs follow the high and low tones and, if all is well, text should appear on the screen. The system will scroll when a displayed line is full or when a line feed is received. In order to familiarize yourself with operation of the LEDs you may want to tune around an unmodulated carrier or CW signal. As the tone increases in frequency, you'll notice the L LED come on, shift to the H LED, and then both LEDs will extinguish as the tone frequency exceeds the filter/decoder passband.

To receive commercial or VHF amateur RTTY, select the 850-Hz filter and shift and tune in the same manner as above. Since the audio shift is wider here, the tuning will be slightly less critical than in the 170-Hz case. Commercial news broadcasts are usually at 67 wpm and NORMAL, weather is 100 wpm and NORMAL, and some ship-to-shore is 100 wpm, 170 Hz, and REVERSE. Many of the commercial broadcasts seem to be between 16.0 and 16.5 MHz. If you happen to run

Fig. 11. Listing of the Baudot code with appropriate decimal and hexadecimal equivalents. The special Timex/Sinclair FIGS codes for the display and keyboard are shown in the last two columns.

across a non-Baudot station or if you select the wrong system parameters, garbage will print on the screen.

To transmit, simply hit SHIFT T, and if you wired the jumper correctly, your rig should switch to transmit. Adjust the output level and mike-gain controls for a reasonable rf output power. Don't overdo it—my TR7 gets plenty hot with only 60 W continuous output power. RTTY isn't like CW; the rig is putting out full power continuously during transmit, and most manufacturers recommend cooling fans for their solid-state gear when running high power in this mode.

Adjust the monitor-level control until the 2125-Hz tone is audible, then type your message. You should hear the space tones intermittently as you type. You can keep your eyes on the keyboard and simply listen for confirmation of character transmission. The 8251 chip gives you a single character buffer (big deal) so you can type a new character while the previous one is being sent.

Note that the computer automatically will send LTRS and FIGS codes where necessary and also will send a CR/LF/LTRS command when you hit the ENTER key, or on the first space after 64 characters are sent with no intervening ENTER. Your transmission is thus automatically keyed to the 80-column printer found on most mechanical and high-priced electronic systems. Also notice that the SPACE key really produces a space; if you want this key to act as a program BREAK, press the key while in the receive mode. In this way, you can return to the T/S operating system. Typing SHIFT R while in the transmit mode returns the system to receive.

Some Baudot FIGS characters are not present on the T/S keyboard for transmission or in the character set for display. The most logical substitute characters I could think of are listed, along with the Baudot character code, in Fig. 11.

Conclusion

Many amateurs feel that frequency-shift RTTY is the ideal communication mode, and with good reason. It has a 3-dB signal-to-noise advantage over machine-decoded CW signals, and information is sent much faster than most manually-decoded CW. In many cases, when an HF band is nearly useless for CW or voice communications, the RTTYers are still going strong. Indeed, I can get about 90% copy with my system tuned to a signal which is weak and barely audible. There is also much satisfaction to be gained in the construction of a project of this nature, allowing you to experiment with a very useful specialized communication mode at minimal cost.■

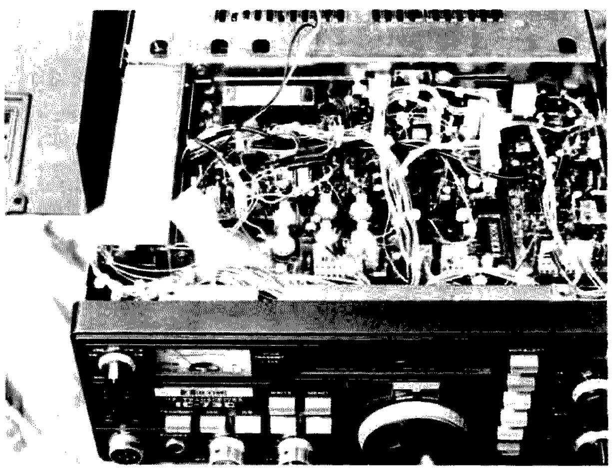
Easy FSK for the IC-730

Don't settle for less than complete.
Four dollars gives you the RTTY the factory left out.

The IC-730.



Top view: The wires for my modification are identified with white tape, here shown going to the pad 1 and pad 2 locations under the calibrate pot on the main board.

Emory D. Young WA4TTO
2403 E. Bolling St.
Savannah GA 31404

Having recently acquired Icom's IC-730, I noticed that it didn't have a RTTY mode. As I wanted to get into RTTY, I had two choices: to build up an AFSK unit or to modify. Being naturally curious, I decided to modify, if possible, and pulled out the schematic.

The PLL has a 13.66-MHz crystal and is calibrated with a 10k pot (R-162) that controls the bias on a varicap diode. By switching a resistance in parallel with the calibrate pot, you can change the frequency of the 13.66-MHz crystal oscillator and the frequency of the rig. See Fig. 1.

First remove the top and bottom covers. In order to gain access to the foil side of the main unit board, you have to remove the 17 plugs that are plugged into the main unit board. Unscrew the four mounting screws. (*Note*: The mounting screws are permanently locked to the main board.)

The coax cable from J14 has to be slid in the wiring harness toward the detector unit in order to have enough slack to turn the main unit board over.

Cut two 15-inch pieces of wire (about 22 gauge) and, referring to Fig. 2, solder one wire to pad 1 and the other wire to pad 2. Be sure to re-

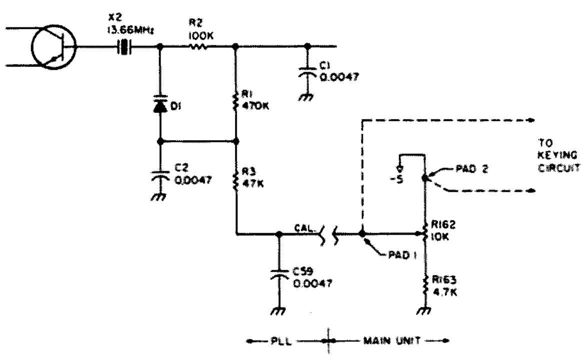


Fig. 1. Schematic.

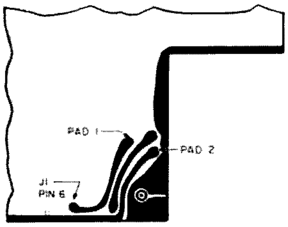

Fig. 2. Foil side of main unit board.

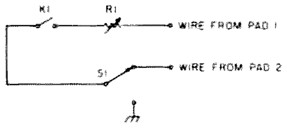

Fig. 3. Keying circuit with shift switch.

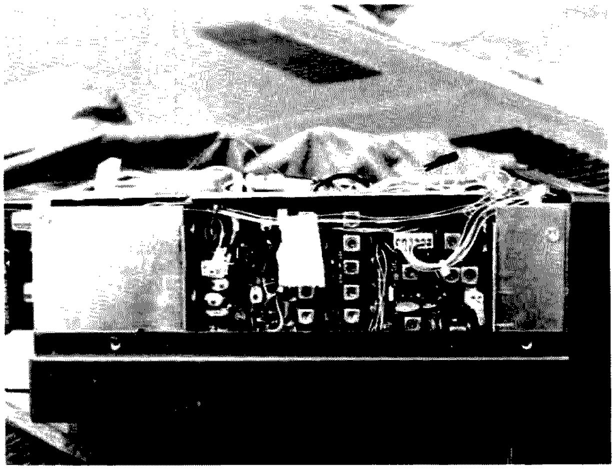

Right-side view showing routing of modification wires to the rear and then straight to molex connector.

member which wire is which, as this is very important. Carefully replace the main unit board and plug the wiring harness back in.

If you don't have the optional marker unit, J15 will be empty, so don't search for the missing plug, as I did.

Remove the 8 screws at each end of the rear panel and unplug the coax cables from J1 and J3 on the low-pass filter board. Run the two wires you soldered back to the accessory socket where you have 13 unused positions just begging to be used. Make up a couple of molex® pins or, if you don't foresee any use for existing accessory connections, cut wire from two of the positions and attach your wires to them. Pin 8 of the existing socket is ground. This done, plug coax cables back in, reassemble the rig, and put the covers back on.

Referring to Fig. 3, K1 is a reed relay and R1 is a 50k pot. S1 is an optional SPDT switch used to select Mark low or Space low. Keying between pad 1 and ground makes Mark low, and keying between pad 1 and pad 2 makes Space low. Adjust R1 for desired shift. Going from Mark low to Space low or vice-versa will require readjustment of R1.

When transmitting, use the AM mode instead of the CW mode, as the 40 Watts in AM are easier on the finals and they can operate for extended periods this way.

I will gladly answer or correspond about any questions you may have if you enclose an SASE. K1 and R1 are stock items at Radio Shack. Molex connectors with their pins also are available at Radio Shack.

So get into RTTY with your IC-730 and this very low-cost modification. It should not cost over $4.00 with all brand-new parts. See you on the bands. ■

73 INTERNATIONAL

Each month, 73 brings you ham-radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73: Amateur Radio's Technical Journal, *Pine Street, Peterborough NH 03458, USA, Attn: Perry Donham KK2Y.*

NEW VK CALLSIGNS

The Department of Communications (DOC) has just released a new block of callsigns for the amateurs in Australia. It is getting as bad as the States, trying to keep up with the suffixes when each means something different. The new suffixes, and what they mean, are as listed below (the space is where the Australian state indicator goes):

Full amateur—VK-FAA to FZZ
Limited amateur—VK-TAA to TSZ
—VK-TUA to TZZ
Novice operator—VK-MAA to MZZ
Combined Limited
and Novice—VK-JAA to JZZ

RECIPROCAL LICENSES

I recently had reason, due to a feedback letter from the States, to check with the DOC on what is required by overseas amateurs when applying for a reciprocal license in Australia.

The main complaint in the letter received was about a clerical error—the wrong form being sent to this gentleman—but some of the points raised by him are worth explaining here, to keep this problem from happening again.

The first thing you must do is to explain fully that you require a reciprocal amateur license to operate in Australia, making sure you state the period you wish to operate. The form to ask for is "RB57 Application Radiocommunication Licence," and you need only to fill in questions No. 4—Name of Applicant, No. 5—Postal Address, and the declaration on the bottom. That's all; forget the rest as this is a multipurpose form. Make sure you apply at least four months prior to leaving for Australia.

After filling in this form, return it with a certified copy of your license, together with Australian $20.00 [about US$21.30—check with your bank] plus a large self-addressed envelope. We know that amateur licenses in the States are free, but we have to pay, at present, A$19.00 per year, and as a reciprocal license is good for a period of one year (whether you stay a year or less), it also costs that. There were questions asked of our DOC by the WIA regarding short-term licenses for overseas amateurs, but it was found that a 3-month license could be even dearer due to administrative costs. At the present time it costs A$1.00 to airmail a large 4½" × 8½" envelope to the States.

The preferred method of payment is by bank check, remembering the difference in currency value plus bank clearance charges. As you are dealing with a government department and not an individual, ten cents over is a lot better than ten cents under when sending over your check! (The right money is preferred.) (Stateside Novice license holders are not able to gain a reciprocal license with Australia.)

Our DOC has a policy of giving all possible aid to overseas amateurs wanting reciprocal licenses, but being a government department, they must abide by government policy.

The preferred method of granting licenses to overseas amateurs is for you to present your current amateur license (or certified copy) at any branch of our capital cities' licensing departments and your VK reciprocal license will be handed over the counter to you with only a five-minute delay.

Another way to go is to get one of your VK on-air friends to get it for you, if he lives near one of our major cities. I am told by the DOC that they will issue one to him for you, providing all the paperwork is correct.

I know that the last thing you want to do is chase after a license when on holiday, but providing it is not the weekend or a local public holiday, the appropriate department will be open during normal working hours and will be only too pleased to issue a reciprocal license over the counter.

There is a good case for an International Amateur License, but with all the different grades plus ever-changing licensing criteria throughout the world, what an administrative headache this would present! I feel that we amateurs would have to pay, in the end, one way or the other, for this privilege.

VK9L—LORD HOWE ISLAND

There have been many requests to our DOC over the years to correct the anomaly that existed with the Lord Howe island callsign, as it had separate country status but still retained the VK2 callsign. You can imagine that this did cause some confusion to overseas stations, unless the station operating signed "Lord Howe Island."

This has now been remedied by our DOC issuing a new block of call letters, VK9LA to VK9LZ. This should make it easier for overseas stations to recognize this call in the future.

The "Down Under DXers' Club" operated last year from Lord Howe Island as VK2LHI with great success. They have stated that they will try to activate this DX spot on a regular basis, at least twice a year during contest operations. As a result, this one should finish very low on the DX Most Wanted List in the near future.

Dick VK2AGT, a permanent resident on Lord Howe Island, is now VK9LH, while the new call for Ken VK2BKE, the other permanent amateur resident, is unknown to me as yet. Ken is well known as a Morse-code instructor for the VK2 division and often takes the on-air slow Morse sessions for this division on 3.550 plus or minus QRM at 09.30 UTC.

MARCONI OR LANDELL DE MOURA?

Guglielmo Marconi is known all around the world as the first man who made a wireless transmission—it happened in 1898. Meanwhile, three years before, in 1893, Roberto Landell de Moura, a Brazilian priest father and a researcher of electrical phenomena, succeeded in transmitting wireless phone signals for about eight kilometers in the city of Sao Paulo. It took him a lot of studying and experimenting without any help and using only poor apparatus he had at home.

Due to his humility, this event was not spread out for the world that time, and it is still unknown except for us Brazilian operators for whom he represents the beginning. You may be sure that it was a Brazilian before Marconi.

CELSO BUSS PY3CB

With deep regret we record the passing of Celso Buss PY3CB (ex PY3APH), one of the most well-known DXers of Brazil. Very young, 44 years old, Celso achieved many awards (one of the first in Brazil to get the Five Bands DXCC, DXCC Honor Roll, etc.), and, above all, was a very kind and charming person.

CECW AWARD

Sponsored by the CW group of the state of Ceara, the CECW award is available to all licensed amateurs for confirmed contacts with five PT7 stations. Among them, three must be CECW members. Contacts must have been made after September 1, 1983, on any amateur band. Only two-way CW mode. No QSLs. Send GCR list of stations worked (call, date, time, band, mode, and report) and 10 IRCs for mailing expenses, to CECW Award, PO Box 546, 60000 Fortaleza, CE, Brazil.

CECW members: PT7s AA, AC, ADC, AI, BTO, CG, EQ, HP, NK, ON, QR, WA, XO, YS, ZD, ZP, and ZZ.

de PY1APS

BRAZILIAN LEAGUE AWARDS

Brazilian Radioamateurs League (LABRE) sponsors four very interesting not-so-easy-to-get awards, encouraging interest in Brazilian areas, American areas, and Atlantic Ocean areas. You can judge yourself and join the fun of them all!

The *WAB (Worked All Brazil) Award*—available to amateurs confirming QSOs with Brazilian stations in all states and Brasilia City, PT2. Special ribbon to confirmed QSOs with Federal Territories of Amapa, PY8 (ex PU8), and Roraima, PV8.

The *WAO (Worked Atlantic Ocean) Award*—available to amateurs confirming QSOs with all 9 Brazilian geographic regions and 21 countries of the Atlantic Ocean. *First Region*: PY1/PP1, *Second Region*: PY2/PP2/PT2, *Third Region*: PY3, *Fourth Region*: PY4, *Fifth Region*: PY5/PP5, *Sixth Region*: PY8/PP6, *Seventh Region*: PY7/PP7/PR7/PS7/PT7, *Eighth Region*: PY8/PP8/PR8/PS8/PT8/PV8/PW8, and *Ninth Region*: PY9/PT9/PY0.

The *WAA (Worked All America) Award*—available to amateurs confirming 45 (forty-five) countries in the American geographic area; one of them must be Brazil.

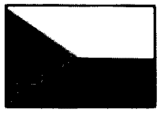
The *DBDX (Brazilian DX Award)*—available to amateurs confirming QSOs with a minimum of 20 (twenty) different countries on the official DXCC list; one of them must be Brazil. Contacts must be on 160, 80, or 40 meters.

Special stickers allowed for additional countries in groups of 10. There are three kinds of certificates: only phone mode, only CW mode, and mixed (phone/CW operation).

All stations must be contacted from the same country. (Only exception when a station moves to another call area or country within a radius of 150 miles from initial location.) Only land stations accepted; no air or maritime mobile accepted.

Contacts are valid over any period of years, with same station license even if with different call letters. Logs with all data as in QSLs, checked by applicant's Award Manager or by two licensed amateurs. All applications must be sent, enclosing 10 IRCs for handling and postage, to LABRE Awards Manager, PO Box 07-0004, 70000 Brasilia, DF, Brazil.

Note: Since March, 1984, PU prefixes identify class-C operators in Brazil, and the PU8 call for Amapa Territory has now changed to PY8. Only PU8 GAA to IZZ calls identify new class-C operators from Amapa. Before then, Amapa's QSLs are considered valid PU8 calls for LABRE's award.



CZECHOSLOVAKIA

Rudolf Karaba (OK3KFO ARC)
Komenskeho 1477

Czechoslovakia

AO-10 IN CZECHOSLOVAKIA

At the beginning of January, 1984, after an operating pause devoted among other things also to the improvement of sets, Ondrej OK3AU resumed his satellite operation which he certainly did not regret being able to do. The number of nice DX contacts with FK8CR, KH6IBA, VK3ZL, W1BIH/PJ2, JR6UPU (Okinawa), VS6HI, and FR7CC was increased in his log. An interesting additional station was LA2PH/MM, with Ken, who had sailed his ship M/T *Thorsholm* for A8X (The United Arab Emirates) and during his contact he found himself not far from C9 (Mozambique). In the second half of January, the expedition LU2A from the South Orkneys was working under the callsign AZ5ZA (SSB). Ondrej also heard the following (operating SSB): VP8NO, JY1, TI2NA, TU2IT, 4U1ITU, EA8JJ, Z25JE, and HL9FZ. The biggest DX was the reception of ZL2 (New Zealand) that is at the very boundary of the communication range AO-10. At the end of January, Ondrej had added up 52 DXCC countries from all six continents.

At AO-10/B another Czechoslovak station appeared, at last. It was Mirek OK1DMS from Marianske Lazne.

* * * * *

New records and new countries in the VHF and UHF band:

• A full use of extraordinary conditions created by a sporadic E layer in June and July last year was made by Jenda OK2BFH, who made contact with more Spanish stations, but also with 9H1CD, CT1AUW (his new country) and especially with EA8XS on the Canary Islands. EA8XS represents not only a new country for OK-land and OK2BFH personally, but also a new Czechoslovak record in the category of propagation by means of a sporadic E layer, 3757 kms, on 16 July 1983.

Jenda was also successful with Perseides contacts; in August, 1983, he had advance non-agreed contacts with SM2ILF, SM3JAW, SM3KJO, and agreed contacts with LA6CU and UA1MC, the last one enduring for 20 minutes with the intensity S9 for up to 3.5 minutes at a time.

• OK1AIY successfully made full use of a license for the 1296-MHz band obtained since 1 July 1983, and as our first station he made contact on the above-mentioned band on 13 September 1983 with Y23FL/P in the German Democratic Republic. Y23FL/P, who is in locator HK14c, made use of a 10-mW and a 15-element yagi. Pavel had a 4 × 15-element loop yagi, 20 Watts, in locator HK28c.

• OK1KHI certainly cannot complain of tropospheric conditions in the second half of October last year. On the 22nd and 23rd the station made 375 contacts from Snezka ranging from EI (Ireland) to UA3 (European USSR) on the 145-MHz band, 78 contacts on the 433-MHz band, the first contact from OK-land with GI4GVS, GU6EFB, and EI6AS—the last one 1525 kms away. Twenty-seven contacts were on the 1296-MHz band, the longest one with G4CWB at a distance of 1257 kms.

• OK1CA had bad luck because he arrived at Snezka on October 26th, but in spite of that he made 16 contacts on the 1296-MHz band, the longest one, 1089 kms, being with G3LTF. On the other hand, on October 28, 1958, he had good luck meeting OK1VR in Snezka who came 25 years earlier after he had broken a long-lasting Czechoslovak record of 1518 kms on the 145-MHz band by contact with GI3GXP.

• Radio club OK1KIR was very successful in the first part of the EME contest that took place on October 29 and 30, 1983. Operators had been working on the 433-MHz band with JA6CZD, OE5JFL, DL9KR, HB9SV, G4EZN, YU1AW, OH6NU, N4GJV, HB9G, W0RRY/5, N9AG, G3LTF, OE9XXI, SM3AKW, K2UYH, I5MSH, DK8MA/P, and on the 1296-MHz band with OE9XXI, K2UYH, OE5JFL, G3LTF, W7GBI, LX1DG, DF0EME, WA8NLC, and YU1AW; even ZL3AAD had been heard.

THE UK SCENE

Most of you probably know that UK amateurs are not allowed to handle third-party traffic. Until recently, the only chink in the authority's armor of anti-third-party traffic handling was in provisions for emergency message origination. Even to do this, though, requires a typically British bureaucratic procedure. An amateur may pass emergency or life-saving traffic only at the request of a designated official.

In theory, then, a public-spirited amateur equipped with, say, 2-meter mobile gear and coming across a serious traffic accident cannot legally request another amateur to QSP a message to the emergency services. In practice, of course, any self-respecting amateur would do everything he could to alleviate the situation he found, and normally the authorities would turn a blind eye (wouldn't they look silly prosecuting in such a case?).

Anyway, there are now some further signs that the days of restrictions on third-party traffic may perhaps be numbered. Non-amateurs may use a licensed station under supervision to pass greeting messages, but only to another station within the UK. The other station may be similarly manned. This provision is aimed at events such as the Jamboree On The Air (JOTA) which is always a popular and well-supported event in the UK. In the 1983 JOTA, some 13,000 Scouts and Guides (Girl Scouts) took part worldwide including no fewer than 455 UK stations.

JOTA contacts from the UK were made with some 50 other countries on HF and via OSCAR 10. There can be no better introduction for youngsters to amateur radio than via their scouting activities. This has been the case for many years but now the Scouts and Guides have the opportunity to use the microphone themselves, albeit for only limited greetings messages.

The Scout headquarters' JOTA station, GB2GP, was officially opened by the chairman of local Epping Forest District Council, who used the greetings message facility to swop felicitations with another civic dignitary, the mayor of Northampton, who opened another JOTA station, GB2NDS, at the same time.

There can be little doubt that being involved in an amateur-radio transmission is far more likely to promote a spark of interest than just watching somebody else. When this interest comes from an elected local representative, the whole amateur movement stands to benefit. Amateur radio is often misunderstood, misquoted, or confused with CB, or just dismissed as boys playing with radios. Any opportunity to demonstrate the finer points of the hobby to others should not be missed.

I was recently the after-dinner speaker guest for a local Round Table (known as Active 20/30 in the US) and I chose to talk about the Amateur Radio Service with the emphasis on service. It never ceases to amaze me how little most people understand of the technology associated with radio and of the part played by amateurs. A demonstration of handie-talkies, pocket-sized HF receivers, OSCARs, and pictures of the space shuttle tends to bring a few glazed looks from the audience but they never again dismiss hams as cranks.

When giving such talks I try to keep away from too much in the way of technicalities and jargon and tend to concentrate on shortwave listening. This is for two reasons—first, it is easier for the uninitiated to follow, and second, it is something the man-in-the-street can easily take up for himself with little outlay and no technical knowledge. How many times, though, do you see demonstration stations at fairs, festivals, and the like, working stations lost in the noise and using nothing but Q-code jargon? We all like to work DX, but when trying to interest the public, a little clarity and plain English will go a long way.

I was in Italy on holiday during World Radio Amateur Day in April. I thought it would be a good idea to take a handie-talkie just to listen to the local 2m traffic (I had no time to apply for a reciprocal license so was not intending to transmit). Despite protests from the XYL about the extra weight, the IC-2E went into the case with a freshly-charged battery pack. When I first decided to use it, 2 days into the trip, I found I had left it switched on! There is a moral to this story, but you must have guessed it by now!

SV1PL inside...

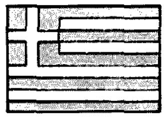
My little vest-pocket stereo FM radio from Toshiba does not cover 2 meters, of course, but the number of band-2 stations around Naples is almost as many as around LA. At least there is the US forces network on 104 MHz which has excellent coverage of the Naples Bay area and is in English (my Italian is rather limited)!

A few days ago I visited Communications 84, the biennial trade exhibition and conference at the National Exhibition Center near Birmingham. It is primarily a showcase for manufacturers of commercial telecommunications gear including switchboards, modems, multiplexers, and so on. This year two particular themes seemed to dominate.

First, a rash of products was aimed at catching the eye of the consumer recently freed to buy his telephone anywhere. Until last year all (legal) telephones and extensions had to be rented from British Telecom. Now, with liberalization, the consumer can buy additional approved instruments from whomever. Needless to say, the UK market is now flooded with telephones from just about everywhere and in just about every shape. (The Mickey Mouse phone I brought back from the US a few years ago has lost its conversational appeal all of a sudden!)

Second, the personal-computer market continues to believe that nobody can survive without communications. Every respectable PC has at least one modem and a local-area-network connection for bulletin boarding or electronic mail. (Or at least that's what the salesmen would have us think.)

Also at the show were a number of exhibitors of specialized or military hardware. They were showing ruggedized HF receivers, backpack radios, Morse decoders, and the like. In every case their demonstrations were tuned to amateur broadcasts. It was most encouraging to see a crowd of professional communicators around a stand watching a CW QSO displayed on a screen.

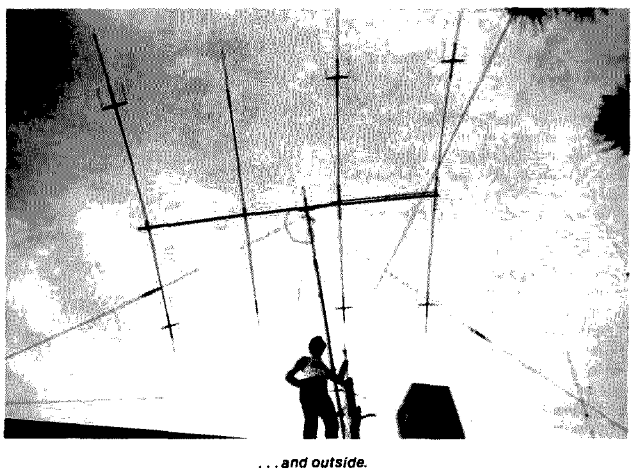


GREECE

Manos Darkadakis SV1IW
Box 23051
Athens 11210
Greece

Continuing the presentation of some SV DXers, this month we have Angelo SV1PL.

But before that, I would like to point out something which I thought of just a few hours after last month's column was traveling to 73 headquarters. What I was trying to say is that HF is not the only place where DXing is taking place. With the tremendous range of AMSAT's new bird, two meters offers a lot of DX now. Besides



...and outside.

that, working with sporadic E openings or meteor scatter or even tropo and aurora can give DX contacts which are equally worth the ones on the HF bands. Therefore I will be more than happy also to present through this column a number of people working above 50 MHz.

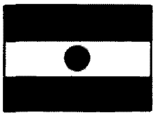
Back to Angelo, now. SV1PL is situated in Marousi in the northeast part of Athens city. Angelo, who is now 34 years old, got his ticket some three years ago, and from the first he was attracted by the HF challenge. Starting with a Kenwood TS-130, he played around for some time with dipoles, verticals, and the like, but after understanding it was a waste of time, he moved to a Hidake three-element beam.

Anyway, he was learning quite fast and after his first year of amateur life, he started to take part in contests and to collect diplomas.

Today, SV1PL has 245 confirmed SSB DXCC contacts and is looking for more. His station consists of the same TS-130, an RF Power Electronics antenna tuner, and an HB443DX-4 four-element, four-band beam antenna from TET. On the low bands Angelo is using an HF5 from Butternut. On the other bands he has the FT-480R and FT-780R from Yaesu (very popular in Greece) for 2m and 70cm respectively. The antennas for those rigs are a 16-element and 19-element F9FT, both of them horizontally polarized.

Finally, there is also a TRS-80 Model I Level II computer equipped with Macrotronics interface and software for RTTY and CW and many other amateur-related programs.

So if you hear SV1PL on the air, do not hesitate to call him; even if you greet him in Spanish or French, he will answer back.



INDIA

Major T. A. Ramakrishnan VU2TN
Manager, Airnet-India
Clara, 5-B, Versova Cross Road
Andheri West
Bombay 400 058
India

GOODNESS IS GRACE!

Whenever you listen to the activity on the 20-meter band, especially around 1530 or so, you will find a regular activity on the DX horizon from India, on 14150 kHz. If you listen carefully and if the few hundred "Ullannas" permit you to listen, you will hear a net in progress. Most of the days, this net would be conducted by a YL. The YL whose voice you will hear is Grace VU2AIG.

Grace and her OM, Dasan VU2AID, are devoted hams in India. They operate from Bombay, and to them hamming is a very important part of their life. Not just working DX or chasing the rare ones, but in being part of the national emergency network, the Airnet-India, which, incidentally, has its own callsign, VU2NET.

With Julia, their only daughter, away at Patna practicing as a doctor, being also a ham (VU2AIJ), this family is a total ham family, with a great determination to carry on the great work of rendering relief to the needy through ham radio.

With only about two years' "driving license" at the mike, you will find Grace a really wonderful person to meet, both on the air and in person. Ever helpful, Grace is goodness itself and goes to any amount of personal troubles to help out the many patients in VU-land who need medicines which are just not available in that country and have to be brought in from outside. Incidentally, the Airnet-India has this unique service offered to the country; there are at least a few hundred families around India who are grateful to Grace for saving the lives of their near and dear.

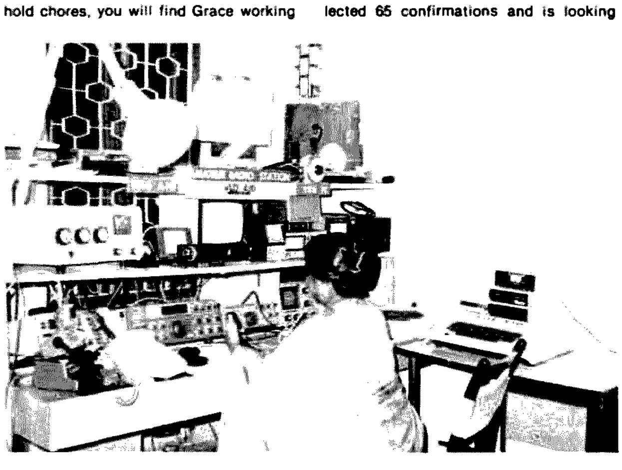
Grace VU2AIG outside...

It works like this—after the net is called, any ham who has a need for medical assistance lists the medicine needed, its source, and the country of origin. Grace then contacts the few sources in DX either by landline or by other means and passes on the requirements to the most likely source. The medicines are procured and put on the next flight to Bombay, and either Grace or OM Dasan collects the same (sometimes even at midnight) and arranges to put the medicines on board the next internal flight. The medicines are collected by the Mr. Needy Ham, who is informed on the air, again through the Airnet-India. Thanks to the wonderful cooperation of the Air India and the Indian Airlines, lives dear to someone are saved.

When she is not busy with her household chores, you will find Grace working DX mostly on the 21- and 28-meter bands. I will bet that you receive her QSLs faster than you post yours, since she QSLs all contacts direct and feels that QSL bureaus are very tardy—so, in case you do want a QSL from Grace, better do it direct!

To keep her active, she has a wonderful shack—HF is covered by a TS-930S, TR-7, TS-430S, and a veritable antenna farm with a three-element beam, a two-element quad, a Butternut vertical, and a number of dipoles which help put a really FB signal out of Bombay. VHF is catered to by a whole lot of equipment with exotic antennas. The shack has minor details like an Apple II computer, a Robot terminal, a word processor, and all the monitoring equipment which would make the shack look like an Indian branch of Radio Shack, indeed!

Unlike many ham families, OM Dasan is a home-brew fiend and thus Grace has all the time to be on the bands. She would like to get her DXCC and has already collected 65 confirmations and is looking forward to the balance. So, in case you have contacted her, do send in your QSL!



...and inside.

While not on the air, Grace, an accomplished pianist, loves to play Chopin and Tchaikovsky. She is also a qualified teacher and thus has endless patience in listening to endless monologues. But most of all, as I said, she loves to help any friend, any ham; thus, as the title reads, goodness is Grace!

THE NEW BANDS IN ISRAEL

In late 1982 the Israeli government ratified the 1979 World Administrative Radio Conference allocations for the new amateur bands. Nearly a year and a half has passed since then, when your faithful reporter made the necessary changes to activate his rig on these bands, loaded his longwire, and gave them a try. The following is a combination of official information, personal experience, and details gleaned from other amateurs.

10 MHz

This is by far the most promising and active of the new bands. As with 24 and 18 MHz, the Class A amateur is allowed 150 Watts peak input while the Class B licensee is limited to 100 Watts. The Class A hams may use 10.100 to 10.150, but the Class B holder is restricted to 10.110 to 10.130 MHz. Both SSB and CW are permitted, not only across the entire band but on 24, 18, and 1.8 MHz as well. Operation must be on a secondary non-interfering basis to the other services that populate this band. There are no further limitations.

You may have raised an eyebrow upon reading that SSB is permitted. The International Amateur Radio Union (IARU) had recommended that only CW be used on this narrow slice of spectrum and indeed most countries permit only Morse operation here.

One Saturday, as our national 40-meter net ended, I suggested that we make a test and requested that everyone with capabilities move up to 30 meters. A dozen stations responded using a variety of rigs and improvised antennas, and we were in the midst of an SSB round table exchanging signal reports and comparing stations. A European station was heard in the background on CW sending "NO SSB," and Vic 4X6GP broke in asking indeed what we were all doing here on SSB. Of course, this was only a test, the band was not crowded, and we were all complying with the terms of our licenses, so Vic was reassured that 10 MHz was not going to be overrun by SSB operations. As it turned out, signals were much better on 40 meters, so we were convinced that this was not the optimum band for local QSOs.

With regard to SSB operation on 10 MHz, Vic told me that during his operations here he had heard only French stations on phone.

How about propagation on 30 meters? An oversimplification is that 10 MHz behaves partly like 20 meters and partly like 40. Actually, skip on this band seems to have a character of its own, but then the fact that most stations here are using low power and unity-gain antennas probably has a bearing on the "feel" of 10 MHz. In a year or so of casual operating, putting out

a hundred Watts of CW into a longwire somewhat directional to Europe and North America, I worked all continents from JA, VK, and ZS to VE and YV with Europeans being commonplace. Vic 4X6GP and Dov 4Z4DX have had similar experiences.

The beauty of 10 MHz is that with the lower maximum usable frequency accompanying the decline in the sunspot cycle, especially in the winter months when 20 meters is as dead as a doornail, one may still hear DX stations coming through. On one such winter night with the higher bands dead and 40 meters choked with European signals and commercial QRM, I could hear both US and Japanese signals, albeit weak, coming through.

On this side, 30 meters is quite full of commercial stations, most on RTTY, no doubt running considerable power as they really push around the S-meter, while at the same time one may have to crank open the gain in order to read amateur signals. My observations are that there are a few "windows" free of commercial QRM and thus useful to amateurs. They are 10.100 to 10.108, 10.120 to 10.126, 10.130 to 10.133 and 10.142 to 10.150. Look for the DK9WCY beacon on 10.144 to check band conditions. At no time here have I experienced overcrowding, in spite of a few kilohertz actually free.

Some of my contacts on 10 MHz have said that 30 meters is what ham radio used to be like. Digging down in the dark depths of my memory, I must agree. Most stations are using low power, simple antennas, and are good CW operators and gentlemen. There is no overcrowding or bad manners. All this has given me the feeling that a lot of the operators here are experienced hams, refugees from what has become routine on the other bands, who are nostalgically looking to capture the spirit of the "good old days."

So far, the voluntary ban on competition on the WARC bands requested by the IARU has been instrumental in preserving the unique character of 10 MHz. Indeed, it was a wise move to keep the band free from contests and certificate-hunting so that the band could be enjoyed for its own qualities alone.

18 and 24 MHz

After the new bands became available, I fired up on 18 and 24 MHz as well, and to the best of my knowledge was the first Israeli to appear on these bands. I'd call CQ, attract a pileup of Europeans, and work everyone calling until I'd dried up the band, as it were. Many of the stations worked were encountered on the other WARC bands, apparently enjoying the novelty of the situation, as was I.

Although I didn't become a frequent user of those two bands, I did notice a gradual dropping off of activity. It got to a point that in spite of good propagation and crowding on the adjacent 21- and 28-MHz "old" bands, these new ones would seem almost dead with occasionally someone putting out a CQ call for ten minutes or more until enticing a reply or giving up. Thus I gradually lost interest in 16 and 24 MHz until I had all but forgotten them.

One day in mid-April this year, Adi 4Z4VG told me that a day previously he had worked VK6RO on 24 MHz. This was probably the first Israel-Australia QSO ever on this band. As they had arranged a sked for the next day, I checked to see that the longwire would still load and immediately worked F9VK on SSB. He was followed by Tom GW3AHN on CW, who told me that using only a dipole he'd already worked 50 countries on this band. VK6RO did show up for his sked, and he was able to read me on CW but not on SSB.

Some countries have imposed tough restrictions on the use of 18 and 24 MHz. Amateurs in the United Kingdom are limited to ten Watts only and are not allowed gain antennas, so they must stick to dipoles or quarter-wavelength verticals.

Here in Israel, power limitations are the same as on 10 MHz. Class A amateurs may use from 18.068 to 18.168 and 24.890 to 24.990 megahertz while B licensees are restricted to 18.109 to 18.130 and 24.910 to 24.950.

It would seem that these two bands are just barely beginning to be explored. No doubt they have great potential; there are few commercial stations in these segments and worldwide propagation is possible, depending on the season.

1.8 MHz (160 Meters)

Although not a new band for most countries, 1.8 MHz was opened in Israel along with the WARC bands. Grade A licensees may use up to 100 Watts input, 1.810 to 1.850, and ten Watts from 1.850 to 2.000 MHz. The class B boys are sadly limited to 10 Watts from 1.810 to 1.850 alone. More details about the "top band" may be found in my column on Riki 4X4NJ's activities here, in the February, 1984, issue of *73*.

At Riki's prompting, in mid-March I finally put up a proper antenna for 160. I chose W1BB's inverted L that I saw in the Canadian *Top Band News* published by Ivan VE3INQ. This simple yet effective antenna certainly proved itself during a band opening when I worked 25 east-coast US stations, "crossing the pond" for the first time on 160.

Dov 4Z4DX did some serious work here in the last season, and along with Riki and myself, we hope that Israeli stations will become less of a rarity on the top band. Antennas are without doubt the biggest obstacle to getting out on 160; however, in the last issue of *HaGal*, the Israel Amateur Radio Club bulletin, Riki has just had published plans for the inverted-L antenna that I just spoke of. Interest here is rising.

When asked what are the advantages of this band, I reply, "Absolutely none!" No doubt this is what makes 160 meters so attractive—the difficulty and the challenge. Today there is not too much required to get a signal around the world on the higher bands, but to span the globe on one-sixty is no mean feat!

These paragraphs sum up the present state of the new bands as experienced here in Israel. As elsewhere, there is only a small percentage of the hams active on these frequencies. These are indeed some of amateur radio's newest frontiers, and there is a lot of exploring to be done.

It would indeed be interesting to read here in the *73* International column the state of the new bands in other countries. This no doubt would provide useful information for those charting out the propagation in these newly available segments of the spectrum.

Via Stradella, 13
20129 Milano
Italy

IARU CONFERENCE AT CEFALU

The IARU Region 1 conference is over and it is now time to have a small inventory of what has happened. The opening speech was made by PA9LOU, chairman of the conference, with thanks to the Italian Ministry of Telecom and welcomes to Mr. R. Baldwin, IARU president, A. Shaio, secretary of IARU Region 2, and to M. Fujioka, secretary of IARU Region 3. The flag of IARU was presented to the participants by the Norwegian delegates, while a station with the special call, IP9IARU, started working and in 6 days made over 10,000 contacts.

Thirty-three nations of Region 1 attended the meeting with delegates while others gave proxy to participants. The meeting was later split into different committees, each one with different duties.

The elections of the Executive Committee resulted in PA9LOU being president for the next three years, following the 10 years he has already been in that position. Also elected was vice president SP5FM. The secretary has always been English: G2MI first, G6CL later, and G2BVN until his death; G5CO filled the vacancy. Elected now was a new but very well-known Englishman, John Allaway G3FKM. Other members now are YU7NQM, EL2BA, and I1RYS.

Here are a few of the results of all the meetings and of all the talks.

1) Emphasis has been given to the situation of 7.0-7.1 MHz. This band is at the present used by many broadcasting stations while it has been assigned to amateur use. A recommendation to all the participants has been made in order to put pressure on the ITU to transfer broadcasting to other sectors of the spectrum.

2) The Region 1 members are committed to give assistance to the countries (mainly in Africa) where the amateur service is jeopardized by the economic situation.

3) A group in charge of a European common license is working on this subject and will continue the study of feasibility.

4) A recommendation to all the countries participating has been made in order to limit the proliferation of special prefixes and contests. (I do not like it!)

5) The 17th of June has been declared QRP day.

6) The automation of the QSL service in many countries will not in the future allow the use of QSLs not in line with the actual size limits of 9 cm × 14 cm.

7) Each participating country will have to work on the local telecom administration in order to have the AMTOR A & B system of RTTY recognized and allowed.

8) The 10-MHz band must not be used to transmit local bulletins and other association news.

9) During worldwide and local contests, a certain portion of the band has to be left free for normal use by amateurs not participating in them.

10) A coordinating committee on propagation and sun activity has been promoted. The coordinator is Alan Taylor of RSGB.

11) The official language of IARU has been confirmed to be English.

12) Where the 50-MHz band is not open to amateurs, it is recommended that the local league start approaching the authorities in order to obtain temporary permission.

13) The R9 144-MHz repeaters have to be deactivated immediately to avoid interferences with OSCAR 10. All local associations are invited to stop the tremendous increase in the number of FM repeaters. The use of FM below 145 MHz has to stop, and the 145,250-145,475 portion of the band will be used for local FM.

14) The beacon band has been extended to 432.8-432.99 MHz.

15) A band plan for 1.3 GHz has been approved.

16) The new WW-Locator has been approved and recommended for immediate implementation.

17) Distance records verified by VHF managers will be coordinated by SM5AGM.

18) The study of propagation above 30 MHz will continue to be made by the RSGB and F8SH.

19) Rules have been established on satellite activities.

* * * * *

April 25, 1874, was the birth date of Guglielmo Marconi, and to commemorate it, a meeting was held near Bologna. In the same room where Marconi made a lot of experiments there is now station IY4FGM, and in a future column I will give a full report of the commemoration.

AMATEUR RADIO IN LIBERIA

Amateurs are confirmed junk collectors. To convert them is hopeless. Their wives have learned to accept this fact and live with it.

The modern age with its transceivers that can do everything has not really changed the amateur. He is innovative and is always trying something. And they are so enthusiastic about their findings that they write about them in *73*. What is more, their articles are read. I am going to build the antenna featured in the February issue, page 10. It promises to be exactly what I need for my club station.

When I came to Africa I found myself without a junk box. The realization crept up on me and developed into a real frustration. Every time I needed something, even a little bolt or nut, I didn't even have a place to dig for it. I wrote to an old friend in the States and asked him to please send me some junk. He did. He sent bolts, nuts, and washers. He sent coils, capacitors, pots, all sorts of things. It was well worth the shipping cost.

It took me two years to get what I would call a working supply of junk. One local company retired an outmoded computer. Another company rebuilt its whole electrical system. Since we are a school, I was invited to salvage whatever I could use. Well, I had a field day! I hauled home relays, meters, transformers, motors, piles of circuit boards, wire of all sizes and shapes, and all sorts of nice things. I am still in the market and looking for whatever I can get but I am reasonably comfortable and happy.

Last week one of my friends here found himself off the air. His power supply had blown two high-Amp voltage-regulating transistors and a high-Amp bridge circuit. The parts store had substitutes for the voltage regulators and my junk box supplied four high-Amp diodes and a heat sink. The radio is back on the air and the radio doesn't even know that its power supply has makeshift parts.

This is the time of the year when I teach budding amateurs, both young and old. To liven the class and bring life to some of the dull theory, I went back to the junk box. I made a spool with two blocks of

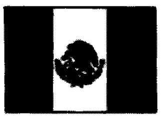
wood and the core form from two rolls of toilet tissue. (These amateurs will find a use for just anything.) I wound on several hundred turns of hook-up wire salvaged from a computer cable. I tested it and added turns until the current from a 120-volt-ac line ran about twenty-seven Amps. When I inserted a solid bar of iron, as shown in the diagram, the current dropped to fifteen Amps. This was not satisfactory at all so I made a laminated core out of some 25 horizontal layers of lengths of steel banding which came to us on shipping crates (sandwiched between more layers, vertically). I taped it together with plastic electrical tape. With this core through the coil, the current was not even measurable with the meters that we have.

I wound a doughnut-shaped coil with about 35 turns and soldered a flashlight bulb across the ends. I then cut a couple of solid-copper and solid-aluminum rings from a piece of pipe (in each case) and with these materials I went to class. The total cost of my "Gee Whiz" show was zero, but the students thoroughly enjoyed it. They saw the laws of physics in action.

The coil with its iron core is a basic transformer primary. The differences in current drawn by the coil with no core, with a solid-iron core, or with a laminated core illustrate one of the factors that affects transformer efficiency. If the core is set so that it extends five or six inches above the coil, it will throw off a copper or an aluminum ring (Lenz's law). If you hold your hand over the core so that the ring cannot escape, it will float in space and get hot. It is now a short-circuited secondary. The coil with its bulb constitutes a secondary with a load. The bulb will glow more and more brightly as the coil is brought nearer to the primary with its core. For an added attraction, drop the whole doughnut coil with its bulb into a beaker of water. The bulb will glow under water if the beaker is set on the primary coil.

This is just a start. With a small iron pan you could fry an egg or boil water in this changing magnetic field.

There are those who say that amateurs, with the advent of the modern integrated circuits, have lost the old spirit. They are wrong. The amateur will always have his junk box and his workshop. Today some amateurs are building an OSCAR and some of the rest of us are building new antennas or fixing power supplies.



MEXICO

Mark K. Toutjian XE1KMT
Apartado Postal 42-048
06470
Mexico, D.F.

I recently got back from a business trip to New York City and was very pleased to have met quite a few colleagues (ham operators). Especially interesting was my visit with the Bridge Radio Club in Brooklyn, at Watchtower Headquarters! Things are really booming for our friends up there in the far north!

Here in Mexico City, rumors are that a new repeater is being (or has been) installed and that a new radio club is being formed. I'll have to get back on the ball and get facts for you, especially if you are planning a trip to Mexico in the near future.

Plans had been made for an expedition to the volcanoes here near Mexico City for the beginning of this year, but my trip to New York got in the way and plans are underway again for our DXpedition through the Paso de Cortez which goes right between the two volcanoes—their names being Popocatepetl (5,452 meters high) and Iztaccihuatl (5,386 meters high). Date of expedition: September 1 and 2, 1984; frequencies: 28.591 (10 meters), 21.375 (15 meters), and 14.307 (20 meters). You probably will find me on frequency (on any of the above settings) all day and all night!

Again I would like to remind our Mexican readers to please rush me any information on current events in their local areas, so as to keep *73* readers informed. To me it's exciting to be able to be part of an expedition or special occasion without even having to leave my home!

It was a pleasure to receive a copy of the Spanish edition of *QSL* right from Spain! Wouldn't it be nice for Wayne Green to entertain our Spanish readers! Imagine *73* in Spanish! I wouldn't mind doing some translating for him myself. It would be worth the effort so as to have top-class technical reading in Mexico and other Spanish-speaking countries! For those who would like information on a Spanish subscription to *QSL*, write to *QSL*, C/. Jerez, 3-Madrid-16, Spain.

I have to apologize to readers for the slight period of no articles due to my recent trip out of the country, and to those who wrote me, such as W9OX, N9FFU, KA0FPJ, and many others. Some asked for information about obtaining a license here in Mexico while on vacation. (Please see my earlier columns with detailed information on this.)

Any of you who would like to contribute ideas for my expedition between the two volcanoes and future expeditions, please contact me immediately. Perhaps you may have ideas for equipment or rare antennas for 2 meters, 10 meters, 15 meters, and 20 meters. Any information will be appreciated.

So, as we say down here south of the border, Hasta pronto amigos! Mucho 73 y DX!

NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

Chatham Islands, ZL7, are composed of two main islands, Chatham and Pitt, and a number of smaller islands. They are located about 850 kilometers from the New Zealand mainland. Chatham Island, the main island, is about 50 kilometers long and has a large lagoon stretching about half its length. Half of the total population of approximately 740 lives in or around the main township of Waitangi. The main industries are farming, fishing, and the associated processing works for these activities.

Amateur-radio activity from Chatham Islands varies, as there are not many permanent resident hams there; most of the amateurs active there are members of the Post Office Radio Station staff who work on the island for specific periods of one or two years' duration. Occasionally an amateur is sent to Chathams for relief purposes, and such a temporary residence is of a shorter period. In this category are Allan ZL2BKM/C (his first trip was in 1983) and ZL7BKM, relieving radio operator for about three months from late May.

The Post Office Radio Station provides varying radio services which include maintaining a 24-hour radio watch on the international distress frequency, 2182 kHz. It routinely broadcasts weather and coastal information and traffic lists to shipping and transmits and accepts telegrams from ships. The station also provides an Aeradio service, air-ground and point-to-point circuits for the Civil Aviation Department. It handles inland telegraph transmitting and receiving, with Gentex offices on the mainland, and Radphone, the radiotelephone link with mainland New Zealand, carrying all the telephone traffic between the islands and the mainland. Radiotelephone messages are "scrambled" en route to maintain confidentiality.

Land mobile, ZLC, the Chatham station's callsign, is the only New Zealand radio station that monitors land-mobile radio circuits, as most of the islanders have radiotelephones in their vehicles for use in case of an emergency. The other service the radio station provides is also unique for a radio station. ZLC provides the night telephone-switched subscriber service which gives the telephone subscribers an emergency facility outside the telephone exchange hours, as the radio station is staffed 24 hours continuously. Anyone requiring assistance can ring in from any one of a number of specified telephones around the islands which are night-connected to the radio station where the watch operator looks after the telephone call.

The Post Office first came to the Chatham Islands in 1856, the mail service being by sea "as opportunity offers." About 1888, when a regular shipping service commenced, this gave a hint of regularity to the mail service. From that time the Post Office offered only a limited service to the residents of the island, until a telephone exchange was opened on the island in 1962.

The radio station was first established at Chathams in September, 1913, with all traffic handled on a radiotelegraph basis. A radiotelephone link was opened between the mainland and Chathams in May, 1953, and in the early days of the radiotelephone link, subscribers had to attend the radio station to make and receive their telephone calls from New Zealand. In August, 1965, the Chathams were linked to the New Zealand Post Office toll system, and subscribers were, from that date, able to make all their toll calls from their homes or offices.

The Chathams group of amateur operators includes Lester ZL7PO, the manager of the N.Z. Post Office Radio Station, Chris ZL7OY, a County Council employee, Ian ZL7TKI, a Works Department employee, and Dave ZL7PA, Tai Rio ZL7TZ, Stephanie ZL7BJE, and George ZL7BSQ, all employees of the Post Office, many of them at the radio station.

BITS 'N' PIECES

Ron Badman ZL1AI, a New Zealand Post Office engineer from Hamilton, has in his spare time designed and built a device to assist visually-impaired amateur operators and listeners. Ron's device is a voice readout which announces the exact frequency on the tuning dial to several decimal places. Similar in principle to a talking clock, the device links a speech-synthesizer chip with the necessary circuitry to convert the visible readout information into sound. The voice chip and the necessary electronics are mounted on a circuit board and installed inside the rig or receiver. The prototype was installed in a Kenwood R600 receiver with a button to activate the readout, which sounds through the same speaker as the audio output.

The device has attracted wide interest in the amateur field, and several of the speech-synthesizer frequency readouts have been made by a Hamilton group for use by some of the estimated 30 or so blind amateur-radio operators in New Zealand.

ROSE CITY CONFERENCE

The 58th Annual NZART Conference and Convention was held at Palmerston North over the weekend of June 3-5 and was called the Rose City Conference because the host city is known as the City of Roses. The host for the weekend conference was a Combined Committee from the Central Districts Branches of NZART consisting of representatives from the Marton, Manawatu, Feilding, Pahiatua, and Dannevirke branches, assisted by members from those branches also.

The Conference was opened on Saturday by ZL1MU, Air Vice-Marshall David M. Crooks, OBE, Chief of Air Staff, Royal New Zealand Air Force, after welcomes were given to delegates and members of NZART from the President Don Mackay ZL3RW and the Palmerston North Mayor, Mr. Brian Elwood.

Amongst the special guests were Dan Wilkenson ZL2AB, who holds amateur license number 2, is the oldest amateur in ZL, and is still active on the air. Dan has been active in amateur radio for 61 years and has held the same callsign for the whole period. Another special guest, Jim Smith KA7APJ from Seattle, Washington, has attended NZART conferences before and is almost a ZL now that he holds the callsign of ZL2BOR. I understand Jim also will be contributing to New Zealand land tax funds now that he has become a landowner "down under."

Amongst the weekend activities, besides the usual domestic conference business sessions on Saturday, were meetings of the various sections of NZART on Sunday. In all there were 320 ZL registrations and one overseas visitor; this would be about 250 amateurs and their partners. Trade displays were featured from the local agents of Yaesu, Kenwood, and Icom, as well as some ZL firms, Southern Cross Electronics, AWA, Tricity House, Ryel Electronics, and Roz Craft Quads.

Amongst the Certificates of Merit awarded by NZART Council before the conclusion of the business sessions was one to Ian Ashley ZL1AOX, an AMSAT member, for his work as an AMSAT Ground Command Station for the Phase III series of craft. The "Stirrers Award" (for the delegate who debates the most contentious points) went to ZL2AUS, the Wanganui delegate.

Next year's NZART Conference, the Garden City Conference, will be held in Christchurch, the Garden City on New Zealand and capitol of ZL3 land in the South Island. All the conference activities will be at the Canterbury University Ilam complex, with displays, technical lectures, discussion groups, and trade displays, besides the usual business sessions of NZART and its associated bodies, the Old-Timers Club, Women Amateur Radio Operators, Amateur Radio Emergency Corps, AMSAT, VHF Forum, etc.

NZART has obtained several pages of *Teletext* free of charge, and amateurs are invited to send in suitable information for inclusion in the *Teletext* pages to *Break-In*, or to Doug Gorman ZL2IY. *Teletext* is reasonably new to New Zealand, and this

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

DARC CORONA 10-METER RTTY CONTEST
1100 to 1700 GMT September 1

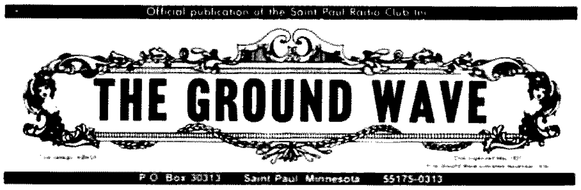
This is the third of four tests during the year sponsored by DARC to promote RTTY activity on the 10-meter band. Each of the four tests is scored separately. Use the recommended portions of the 10-meter band.

EXCHANGE:

RST, QSO number, and name. US stations also give state.

SCORING:

Each station can be contacted only once. Each completed two-way RTTY QSO is worth 1 point. Multipliers include the WAE and DXCC lists, each district in VE/VO and VK, plus each different US



NEWSLETTER OF THE MONTH

How do we pick a monthly winner in our newsletter contest? What are the criteria? Flashy graphics? Length? A flipped coin? Many editors and club members have been asking just what must be done to get their publication chosen out of the hundreds of newsletters we review each month.

Here's the magic formula: consistency. That's it. This month's winner, *THE GROUND WAVE*, is a perfect example. Month after month, Editor Marv Mahre WØMGI and the St. Paul Radio Club, Inc., put out a quality publication. It's not the longest one we see, or the flashiest, but it's always interesting. It's full of news and reports about the club and its members, complete with revealing pictures.

Look at your club's newsletter. Can it stand up next to *THE GROUND WAVE*? Do your members read it cover to cover or consistently toss it onto the rubbish heap?

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

CALENDAR

Sep 1	DARC Corona 10-Meter RTTY Contest #3
Sep 8-9	ARRL VHF QSO Party
Sep 15-16	Ohio QSO Party
Sep 15-16	CAN-AM Contest—Phone
Sep 15-17	Washington State QSO Party
Sep 15-17	Kansas State QSO Party
Sep 21-23	Maine QSO Party
Sep 22-23	Late Summer QRP CW Activity Weekend
Sep 22-23	CAN-AM Contest—CW

Dec 1-2	ARRL 160-Meter Contest
Dec 8-9	ARRL 10-Meter Contest
Dec 26-Jan 1	QRP Winter Sports—CW
Dec 30	Canada Contest

RESULTS

KE5CV, KD7P/KH2, K3TUP, AND I4KDJ: 1984 WORLD 40-METER SSB CHAMPS

"Big signals from Texas," states VE3NVO. "I made 143 QSOs in an hour!" said WC4E, overwhelmed with all the activity. "An excellent contest. . .at 24 hours, the XYL can almost stand it!" comments station K3TUP.

The 1984 40-Meter World Championship event is now history. There were some good times and along with that, bad. For the most part, propagation was spotty at best. From the outset, however, persistence paid off for those who chose to stick it out through the wee morning hours. The later in the evening and the earlier in the morning it got, the better conditions became.

From the looks of the scores, stations in Europe and Asia had a field day working each other and had even greater success increasing their DX totals working within their own continents. Stations in Asia seemed to have had better luck working the USA than their counterparts in Europe. Stateside, the same held true. While the DX countries worked were fewer than in years previous, the QSO counts within the States brought new records for some.

Analyzing the entries, over 85 individual DX countries were logged by those participating in the contest. With that kind of support, it is unfortunate that more DX stations don't send in their contest logs—most would be award winners!

In the single-operator category, only 5210 points separated the first and second place W/VE stations. After all the smoke had settled, KE5CV had risen to become the 1984 World 40-Meter SSB Champion. With 1020 QSOs, 55 states and provinces, and 33 DX countries, a total of 473,000 contest points were accumulated. A fantastic job for such rugged conditions—truly a championship class of operation.

The top three stations, KE5CV, KE5IV, and W1WEF, all surpassed the rest of the field by nearly half again as many QSOs. KE5CV and W1WEF each recorded new World-Championship QSO records. W1WEF had more QSOs in his operating class than anybody. Stations with 500 or more QSOs included: W1WEF (1042), KE5CV (1020), KE5IV (953), KAIGG (676), KQ1F (645), KI2G (643), KB5FU (613), NC2Y (613), K1KJT (594), WD8IVL (593), KI7M (585), KD4TQ (562), and K9MWM/Ø (539).

For DX stations, KD7P/KH2 in Guam captured the World Championship in his single-operator class. Propagation stateside wasn't the best, as only 20 states and provinces were accumulated. A total of 470 QSOs were conducted, however, and 36 DX countries were worked for a total of 228,200 contest points.

How do the record performances of this year's single operators compare with records of prior years? Let's look at contest QSO record totals and see how some fared:

W1WEF	1984	1042	W9RE	1982	851
KE5CV	1984	1020	N3AMK	1982	771
VE5DX	1982	972	KA1XN	1982	761
KE5IV	1984	953	WB8JBM	1982	759
KK9A	1982	856	KC5NQ	1983	756

Many stations in the single-operator class managed to work all states. As before in previous contests, Canadian provinces were at a premium. That apparently holds true in all contests, however.

Stations with 50 or more states and provinces to their credit included: KE5IV (57), NC2Y (56), KE5CV (55), W1WEF (55), KB5FU (55), KQ1F (54), K4JPD (53), KA1GG (53), KD4TQ (52), VE3MFA (52), KA7DLV (51), KI2G (50), W4TMR (50), WD8IVL (50), KT1J (50), KVØI (50), and N8CXX (50).

For W/VE contestants, KE5IV, KE5CV, VE3MFP, VE3MFA, and K9MWM/Ø were the only stations with 30 or more DX countries worked. They tallied 36, 33, 32, 31, and 31 countries respectively. For DX stations in the same category, 4U1ITU worked 44 countries, followed by OK1TN (42), EA3CCN (42), PY5EG (41), ZL1BQD (40), KD7P/KH2 (36), LX1JX (32), and JH3TKM (30).

In the multi-operator class of operation, the new World Champion for W/VE stations is the crew from Pennsylvania station K3TUP. Not only did they tally 538,095 contest points, the next to the largest score in the entire contest (I4KDJ had 545,090 points total), but also they came very close to setting a new World Championship QSO record, falling short of their last year's world record by only 18 QSOs. K3TUP worked 1196 stations, 56 states and provinces, and 31 DX countries—these folks were definitely burning the midnight oil, rotating up to 7 operators at the station. A superb job, to say the least.

Compared to previous contests, K3TUP now holds, in his class, both the world record and the second-highest QSO count in the World Championship contest. The top ten are:

K3TUP	1983	1214	KD4TQ	1982	972
K3TUP	1984	1196	W2ZQ	1984	944
K8ND	1983	1129	NW4B	1984	930
N9NB	1982	1098	KYØS	1984	928
K9EC	1984	1008	NA4L	1984	911

Nearly all the North American multi-operator entries worked all 50 states, with Canadian provinces again being the shortfall. Stations with 50 or more W/VE multipliers included: NW4B (57), K3TUP (56), K9EC (55), WA3SPJ (55), KYØS (54), NA4L (54), W2ZQ (54), KS9O (54), WA6PVA (54), KA4RDG (53), KM8U (53), KBØQA (53), KE6WA (52), and W9ZX (52).

Stations in Europe (as can be expected) managed to work predominately within their own continent to build their contest scores. I4KDJ was the world top multi-operator DX station with 638 QSOs, 25 states and provinces, 68 DX countries, and 545,090 points. Unfortunately, this year propagation to the states was almost nonexistent. Following I4KDJ, with 66 countries worked, were OK1KSO (64), DL8NBE (46), NW4B (32), K3TUP (31), and KYØS (30).

Analyzing the contest logs for this year's event and comparing them to those previous, we find some interesting statistics on antennas which will give you an idea how amateurs are equipping their stations.

ANTENNAS USED (%) IN THE 40-METER CONTEST

	1982	1983	1984
Dipole/inverted vee	39.8	44.6	45.6
1/4-wave vertical	13.9	4.8	2.6
Trap vertical	9.3	11.5	4.4
2-element yagi	7.0	9.6	7.0
1/4-wave sloper	4.6	.9	10.6
1/2-wave sloper	2.3	6.7	1.8
Delta loop	9.3	3.8	1.8
2-el. wire beam	2.3	0	2.6
3- or 4-el. yagi	2.3	9.5	15.7
Longwire	0	4.9	.6
1- or 2-el. quad loop	2.3	0	.9
Bobtail curtain	2.3	0	2.6
Other	4.6	3.7	3.8

Reviewing the antenna survey, one can quickly realize the influence of antenna articles which appeared during the past couple of years in major amateur-radio publications. We see a trend moving from the trap vertical to a 1/4-wave type; 3- and 4-element beams are now more dominant than ever before, and because of recent articles on sloper systems, we see more amateurs home-brewing their own, for contesting purposes especially.

As I talked with many of you on the air, it seemed that many plans were made during the summer to erect that new array. I hope you didn't procrastinate as I did. The 2-element yagi never grew that 3rd element nor the additional boom length. With only months to go before the 4th annual event, we all have time to get our systems ready for greater accomplishments. Then again, maybe that 40-meter dipole will do me another year? Meet me on the band in January and we'll find out how well each other's antenna projects panned out. That's January 14, 1985, for the 4th annual 40-Meter SSB World Championship Contest.

In the meantime, you might send for the 1985 rules and contest summary sheets. Forward an SASE to the 40-meter contest chairman, Dennis Younker NE6I, 43261 Sixth Street East, Lancaster CA 93535. See ya on the band!—*Bill Gosney KE7C.*

40-METER CONTEST SOAPBOX

OE1WWL	No propagation to the States this time!
N2EEC	A newly-discovered, fun contest! One I'll support from now on.
W2ZQ	This multi-op station had 27 operators!
VE3DWE	My first contest attempt.
VE3MFP	Disappointed in the activity at first but it sure picked up later, without doubt! Must have been propagation.
VE3NVO	Big signals from Texas during late night and early morning. Wish I had a beam???
WA3SPJ	Propagation not as good as I hoped. The European opening never came. Still the best of the seven contests I enter each year!
K3TUP	This is an excellent contest. At 24 hours, the XYL can almost stand it.
WC4E	Made 143 QSOs in an hour! Wish this contest didn't conflict with the ARRL QSO party.
W4TMR	An excellent contest—had a great time.
KB5FU	5 new countries and 2 new zones including zone 18. Not bad for a few hours' work.
WA8PVA	Very disappointed I couldn't find a Maine station for WAS. The 4-element beam came down 5 days before the contest.
ZS6WB	Thunderstorms—and QRN level of 20 dB over S9 from 1400–1700Z.
KE7C	Heard nearly 50 countries conversing with one another but few were listening crossband in the US segment.
WD8NHN	Hard to work a contest and run a business. Would like to have spent more time on the air.
KM8U	First time for us to work 48 states, KL7, and KH6 all in one night on this band.
JH9EPA	Good contest.
EA9KQ	Poor conditions to the USA.
KG9O	Only worked 4 hours. Had a great time nevertheless. Next year I hope to spend the entire time contesting.

state. The final score is the total number of QSOs times the total multiplier.

AWARDS:

Awards to the leading stations in each class with a reasonable score present. Operating classes include: Class A for single or multi-op and Class B for SWLs.

ENTRIES:

Official logs are recommended and are available from the contest manager (SASE or IRCs are appreciated). Logs must contain name, call, and full address of participant. Also show class, times in GMT, exchange, and final score. SWLs apply to the rules accordingly. Logs must be received within 30 days after each test. Send all entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee, West Germany.

The remaining contest period is on November 3rd.

WASHINGTON STATE QSO PARTY

0100 to 0700 GMT September 15
1300 GMT September 15 to 0700 GMT September 16
1300 GMT September 16 to 0100 GMT September 17

The nineteenth annual contest sponsored by the Boeing Employees' Amateur Radio Society (BEARS) is divided into 3 operating periods as shown. All amateurs are invited to participate. All bands (except 10.10 to 10.15 MHz) and modes may be used, but no CW QSOs are allowed in the phone bands. Stations may be worked once on each band and mode for contact points and more than once each band/mode if they are additional multipliers.

EXCHANGE:

QSO number, RS(T), and state, province, country, or Washington county.

FREQUENCIES:

Phone—1815, 3925, 7260, 14280, 21380, and 28580; CW—1805, 3560, 7060, 14060, 21060, and 28180; Novice—3725, 7125, 21150, and 28160.

SCORING:

Washington stations score 2 points for each phone contact and 3 points for each CW contact, including contacts with other Washington stations. Multiply QSO points by the total number of different states, Canadian provinces, and other foreign countries worked.

All others score 2 points for each phone contact and 3 points for each CW contact with a Washington station. Multiply QSO points by the total number of different Washington counties worked (39 maximum). There will be an extra multiplier of one for each group of 8 contacts with the same Washington county for all non-Washington stations.

AWARDS:

Certificates will be awarded to the highest-scoring station (both single and multi-operator) in each state, Canadian province, foreign country, and Washington county. Additional certificates may be issued at the discretion of the Contest Committee. Worked Five BEARS Awards are also available to anyone working 5 club members before, during, or after the QSO Party (unless previously issued). All QSO Party entries will be screened by the Contest Committee for possible Worked Five BEARS Awards. Worked Three BEAR Cubs Awards are also available for working 3 Novice members. All BEARS Awards besides OSO Party certificates are handled by Roy Brashear W7RJW, 5711 South 129th Street, Seattle WA 98178. (See page

RESULTS

N4BAA, K1WW, AND ZL1BQD: 1984 WORLD 75-METER SSB CHAMPS

"Great contest," states 4U1ITU. "Sounded like a madhouse over here in Geneva." "The DX was great," says NA4L, who worked some new ones. "Worked all 50 states in one night," crowed W4TMR.

For many, the contest meant getting on for a new state or just adding to DXCC totals. For others, this year's event was nothing short of pure (excuse the expression) blood and guts!

As we compare the scores to those of prior years, you can see, as KI0F stated, the quality of operators—not to mention the quantity of stations heard on the air—is getting better with each and every event. I wonder how many still had the energy to stay up and watch a football game Sunday afternoon? From the looks of the QSO count, it looks like some operators never went to bed at all!

Congratulations to N4BAA, the 1984 World Champion for the single-operator category. I listened to Jose from time to time, and boy, was he ever going to town! You'll note he outperformed Larry N7DF in multipliers, which says he had a definite advantage in working DX countries. Nonetheless, it was a very close race considering that N7DF tallied 1076 QSOs for a new world record for 75-meter QSOs, outdoing N4BAA by 182 Qs! See the stats below. Whew, that's a lot of contacts for 75 meters . . . great job, Larry!

N7DF	1984	1076
N4BAA	1984	894
N5AU (K5ZD op)	1983	777
N8II	1983	730
K0HA	1984	725
KG1E	1983	722
N2NU	1984	722
AD0O	1984	721
N7DF	1982	700
KA1XN	1984	682

W/VE stations this year in the single-operator class with 500 or more QSOs included N7DF (1076), N4BAA (894), K0HA (725), N2NU (722), AD0O (721), KA1XN (682), K0CS (608), KB3A (608), KC8JH (600), KV0I (574), WA1UJU (533), W4TMR (517), and W5VUX (515). The list steadily grows each year as sunspot activity favors 75-meter operation.

In the DX world, hats off to ZL1BQD of New Zealand, who became the 1984 75-meter champion for single-operator DX stations. With nearly 75 multipliers to his credit, Mr. Runciman tallied 137,625 contest points. His score nearly doubled that of second-place finisher EA3CCN of Spain. Like these two fellas, we hope our amateur friends worldwide will continue to support this annual event. We all look forward to meeting you on 75—a lot of us for that first-time contact.

In the multi-operator category, this year's World Champ for 75 meters is Ray K1WW (with KR1V sharing the mike). This New Hampshire station accumulated 675 QSOs and 98 multipliers for a winning contest score of 380,730 points. Only 34 QSOs and 1 multiplier separated Ray and second-place finishers (NA4L and company). While the stats appear close, Ray did manage to work more DX stations, giving him the point advantage he needed to win. Both crews are to be commended!

Not to be forgotten are this year's accomplishments of station K9EC, who finished 3rd place overall. K9EC came within 19 QSOs of setting a new world record for 75-meter multi-operator stations. Refer to the statistics below:

N9NC	1982	793
K9EC	1984	774
K1WW	1984	675
N4TY	1983	655
NA4L	1984	641
KI4DC	1984	629
KS9O	1984	594
KM8U	1984	584
KA4JNC	1983	571
VE2ZP	1982	567

Probably one of the greatest challenges facing all of us each year is our insistence during the summer (some of us wait until it snows) to home-brew still a better antenna than we already have, for next year's event. I'm sure all of us have said it at one time or another. (I guess that's my own guilt coming through since I've been consulting Rush W7RM about a respectable bobtail for 75.)

It seems for this band, however, that the experimenter's instinct has not lost its grasp. From the comparison chart you can see that year after year our contestants favor the inverted vee or dipole, but more and more are putting up various kinds of second 75-meter antennas and giving them a try.

ANTENNAS USED (%) IN THE 75-METER CONTEST

	1982	1983	1984
Inverted vee/dipole	43.8	65.9	38.9
1/4-wave vertical	8.3	11.1	9.6
1/2-wave sloper		2.4	6.3
1/2-wave multi-sloper			5.3
1/4-wave sloper	11.1	5.3	4.2
Phased vertical	5.5	1.1	4.2
2-element wire array	5.5	1.1	9.5
Inverted-L	2.7	2.2	5.3
Full-wave loop	11.1	5.4	5.3
Zepp			4.2
Discage array			3.6
Longwire	7.2	3.3	.9
Bazooka	2.8	1.5	.9
Bobtail	2.0	.7	.9
6-element vertical			.9

Contest certificates have been processed and mailed. Should you have a question regarding the 1984 contest or the issuance of a contest award, contact the 75-meter contest chairman directly. Write Jose Castillo, 1832 Highland Drive, Amelia Island FL 32034.

So it's the end of another World Championship. The 1985 75-Meter SSB Contest is only months away. Mark January 13, 1985, on your calendar. We hope you plan to participate. And please, turn in your contest logs to the contest chairman even if you worked only a few contacts. As you can see from the results, you could be a winner even with a lower-than-average score! Start pruning that sloper; we'll see you in the test!—*Bill Gosney KE7C.*

75-METER CONTEST SOAPBOX

ZL1BQD	Real good contest—keep it up!
WA3SPJ	My best year ever! Hope to get a better antenna up for next year's contest. 86 QSOs the first hour. Would like to see club scores, also.
N4BAA	Looks like the test is catching on. Lot of activity all night.
KD4IC	Extremely good contest!
NA4L	The DX was great.
W4TMR	Excellent contest. Looking forward to next year. Had a great time working all 50 states in one night!
KE5IV	Nothing like getting the 75-meter steerable array up a week after the contest—my normal good planning!
AA6EE	Better activity this year.
EA7ABW	There was no information about the contest in our Spanish magazine. (*Ed. note: We advertised the event in nearly 60 different international publications.*)
KC7PA	Lots of activity. Propagation great all night. Can't wait until next year.
WD8VEN	Hope to do better next year!
KS9O	Biggest thrill was working DL4TL at 1055Z. That's 11:55 am local time in West Germany. There was plenty of DX, especially in the South Pacific and JAs.
KI0F	A very fine contest again this year. Seems the quality of operators is getting better each year of this event. Still one of the better contests going!
4U1ITU	Great contest. Sounded like a madhouse over here with all the stations calling. Keep it up 73, you have a winner!

28 of the August, 1979, issue of *73* for more details.)

ENTRIES:

Logs must show dates/times in GMT, stations worked, exchanges sent and received, bands and modes used, and scores claimed. Include a dupe sheet for entries with more than 200 QSOs. Each entry must include a signed statement that the decision of the Contest Committee will be accepted as final. No logs can be returned. Results of the QSO Party will be mailed to all entrants and an SASE is *not* required. Log sheets and summary sheets must be postmarked no later than October 17th and sent to: Boeing Employees' Amateur Radio Society, c/o Willis D. Propst K7RS, 18415 38th Avenue South, Seattle WA 98188.

KANSAS STATE QSO PARTY

0100 to 0700 GMT September 15
1300 GMT September 15 to 0700 GMT September 16
1300 GMT September 16 to 0100 GMT September 17

This is the third annual contest sponsored by the Boeing Employees' Amateur Radio Society of Wichita (BEARS0) and all amateurs are invited to participate. Use all bands and modes. Stations may be worked once on each band and each mode for contact points, more than once each band/mode if they are additional multipliers.

EXCHANGE:

QSO number; RS(T); and state, Canadian province, foreign country, or Kansas county.

FREQUENCIES:

Phone—1815, 3925, 7260, 14280, 21380, and 28580; CW—1805, 3560, 7060, 14060, 21060, and 28160; Novice—3725, 7125, 21150, and 28160.

SCORING:

Kansas stations score two points for each phone contact and three points for each CW contact, including contacts with other Kansas stations. Multiply contact points by the total number of different states, Canadian provinces, and other foreign countries worked. All others score two points for each phone contact and three points for each CW contact with a Kansas station. Multiply contact points by the total number of different Kansas counties worked (105 maximum). For all stations multipliers are counted only *once*

regardless of how many bands or modes they are worked on. However, there will be an additional multiplier of one for each group of eight contacts with the same Kansas county for all non-Kansas stations.

AWARDS:

Certificates will be awarded to the highest-scoring station (both single and multi-operator) in each state, Canadian province, foreign country, and Kansas county. Additional certificates may be awarded at the discretion of the Contest Committee.

Worked Five Kansas BEARS Awards are also available to anyone working five club members before, during, or after the QSO Party. All QSO Party entries will be screened by the Contest Committee for possible Worked Five Kansas BEARS Awards. All Kansas BEARS Awards are administered by Mike Thornton WAØTAH, contest chairman.

ENTRIES:

Logs must show dates and times in GMT, stations worked, exchanges sent and received, bands and modes used, and scores claimed. Include a dupe sheet for entries with more than 200 QSOs. Each entry must include a signed statement that the decision of the Contest Committee will be accepted as final. No logs can be returned. Log and summary sheets are available for an SASE from the contest chairman. Entries must be postmarked no later than October 22nd and sent to: Boeing Employees' Amateur Radio Society of Wichita, c/o Mike Thornton WAØTAH, 1645 Lexington, Wichita KS 67218.

OHIO QSO PARTY
1400 GMT September 15 to 0500 GMT September 16
1300 to 1900 GMT September 16

Sponsored by the Cuyahoga Falls Amateur Radio Club, the contest is open to all radio amateurs worldwide. Each station may work a maximum of 12 hours during the contest period.

EXCHANGE:

RS(T) and state, VE province, DXCC country, or Ohio county.

SCORING:

Score 2 points for each contact with an Ohio station. Contacts with a Falls member will be worth 5 points and a contact with W8VPV, the club station, will count 25 points. Club members will identify themselves. Outside Ohio, multiply your total QSO points by the number of Ohio counties worked on all bands. Ohio stations will score 5 points for out-of-state contacts plus the member and club station bonuses. Multiply your QSO point total times the sum of states, VE provinces, and DXCC countries on each band. All stations running output power less than 5 Watts, multiply final score by 3; 5 to 200 Watts, multiply by 1.5, and over 200 Watts, by 1.

FREQUENCIES:

Phone—1890, 3900, 7230, 14230, 21360, and 28510; CW—1805, 3530, 7030, 14030, 21030, and 28010; Novice—3715, 7115, 21115, and 28115.

Club station W8VPV will be found on or near these frequencies.

AWARDS:

Plaques to the top station in Ohio and outside Ohio. Certificates to the top station in Ohio county, state, VE province, and DXCC country with two or more entries.

ENTRIES:

Mailing deadline is October 13th. Please include a summary sheet with number of contacts and multipliers, output power and signed declaration, plus total score along with log. Stations with 200 or more contacts should also include dupe sheets. Mail entries to: Anthony Luscre KA8NRC, N. Norman Dr., Stow OH 44224.

Starts: 1800 GMT September 22
Ends: 1800 GMT September 23

Sponsored by the Ontario Contest Club and Canadian Radio Relay League, the contest is held to increase friendships among Canadian and American amateurs and to provide a means of measuring operating skills and equipment performance.

Categories of competition include (1) single operator, allband, single band, and QRP, but must be stations operated by the station licensee; (2) multi-operator, single-transmitter stations operated by more than one operator, or a single operator other than the licensee.

Multi-operator stations can operate the full 24-hour period. Single-operator stations can operate only a maximum of 20 hours with one or two rest periods totaling a minimum of four hours, which must be clearly marked in the log. Any further rest periods do not need to be logged.

Use all bands: 1.8, 3.5, 7, 14, 21, and 28 MHz with the US General portion of the bands recommended. For single-band entries, any band can be selected. All single-band entries will be judged in one category. It is up to the contestant to select the band that can bring him the highest score. For QRP entries, a maximum of 10 Watts input is allowed for use during the entire duration of the contest.

EXCHANGE:

RS(T) signal report, sequential QSO number starting with 001, plus multiplier area abbreviation—in that order. The multiplier abbreviation is the usual two-letter postal abbreviation for the 50 US states, CN for Caribbean (KC4, KG4, KP1, KP2, KS4, KV4, and their A-, N-, and W- prefix equivalents), PC for Pacific (rest of US possessions and Antarctica). Canadians will use NL—VO1 and VO2, NB—New Brunswick, NS—Nova Scotia, PE—Prince

RESULTS

WA2SPL, LC2CJ, EA3CCN, AND K9ZUH: 1984 WORLD 160-METER SSB CHAMPS

This was the year of champions on 160! New world records were set in various categories despite propagation to other parts of the world being at an all-time low. The QSO count has never been greater. Participation was at an all-time high, and the 160 World Championships continue to show steady growth year after year. In 1980 there were 569 participants, and those for the next four years, respectively, were 917, 1482, 1553, and this year, 1741.

For the single-operator class, Joe WA2SPL of New York State is the 160-Meter World Champion for 1984. With a tremendous score of 490,985 contest points, he managed 1098 QSOs, 59 states and provinces, and 24 DX countries. Joe's ability to land the far-off DX contacts made the biggest difference between his score and the well-known second-place finisher, Larry N7DF (now out of Kansas), who set a new world QSO record for the band. Apparently, Joe had a direct line to Europe, working several countries that mid-west and far-west stations couldn't. Super work, WA2SPL—typical of a true champion!

Oh, and speaking of world champions and world records, here's a glance at the QSO tally and how our contestants this year put in a big showing at the top of the list of 12 best.

N7DF	1984	1125
W9RE	1982	1118
WA2SPL	1984	1098
KC8P	1984	1048
VE3CDX	1984	1003
KØHA	1984	991
WØEJ	1984	986
W8LRL	1982	982
KØRF	1984	959
KC8JH	1984	950
WB3CGC	1982	932
KC8JH	1983	900

For the most part, everyone working 200 contacts or more managed to work all states or came within a state or two of accomplishing that. Not all Canadian provinces were represented, so it was a bit difficult to get a total sweep of the United States and Canada. WA2SPL led the pack with 59 states and provinces, followed by KC8P (58), WØEJ (58), VE1YX (58), K4JLD (58), KC8JH (57), KØHA (57), W3TS (57), N9DQS (57), N7DF (58), VE3CDX (56), K9RF (56), K7VIC (56), N8CKG (56), KX4X (56), W1RR (55), W2FCR (55), W4TMR (55), WA1UJU (55), K1LPS (55), KQ1F (55), KD4RI (54), AF1T (53), K8HHZ (53), KØSTF (52), KA7AUH (52), K1KNQ (52), VE5RA (51), WA9TZE (51), KR9G (51), WA5NFC (50), K7IDX (50), KC9FC (50).

WA2SPL amazed us all working 24 DX countries during the contest. Most of us weren't even aware there was DX on the band! Joe was followed by W1RR and VE1YX with 17 countries apiece, KC8JH (13), K8RF (8), VE3CDX (7), K7VIC (6), and N7DF, KC8P, KØHA, W2FCR, KD4NI, KA1YR, K8HHZ, K1LPS, and KA7BRE with 5 DX countries each.

For single-operator DX stations, Jorge EA3CCN of Spain is this year's World DX Champion. Jorge found the conditions to be very poor, to say the least, but his persistence finally paid him dividends. His only outlet was to work other European stations on the band—he heard only one station from the USA. Only 21 QSOs separated the champion and the second-place finisher, SP5INA of Poland.

G3XTT of England led all DX stations, working a total of 38 DX countries while he was followed closely by SP5INA of Poland who recorded 31 countries and World Champion EA3CNN of Spain with 27 DX countries earned.

With extremely poor conditions to the North American continent, Irish station EI4DW managed to lead the multiplier list by working 4 US states and Canadian provinces, while EA3CCN totaled 3.

In the multi-operator class, Jay K9ZUH (assisted by WB9PXR) of Indiana is the new 160-Meter World Champ for the W/VE category. Jay's station had 633 QSOs, 52 states and provinces, and 2 DX countries, giving him a contest total of 171,450 points. There was a difference of only 65 QSOs between Jay and the second-place staff of Kansas contestant W9CEM.

Compared with the results of years past, this year's QSO count was considerably lower. Here is the listing of the top 10 as it currently stands:

K8ND	1983	1001	W4CN	1982	804
WB8JBM	1983	897	AK2E	1982	686
W4CN	1983	690	K9ZUH	1982	677
WA2SPL	1983	879	N7DF	1983	684
W8NGO	1982	877	K9ZUH	1984	633

For DX multi-operator stations, LZ2CJ stands out considerably with 384 contacts. As the new World Champion for this category, this score and QSO count set a new 5-year record. A tip of the hat to LZ2CJ and his SWL assistant, LZ2961—Thank you both for your support.

Many have written often asking what kinds of stations are being operated by the top contenders. This year we thought we would extract that data for you from the top 5 stations (some contestants did list their equipment) and let you see for yourself:

Single Operator Class:

Call	*OTH*	*QSOs*	*St/Pr*	*DX*	*Antenna*
WA2SPL	NY	1098	59	24	Inverted vee, beverage
N7DF	KS	1125	58	5	
KC8JH	OH	950	57	13	Inverted vee
KC8P	MI	1048	58	5	Inverted vee
VE3CDX	ONT	1003	56	7	Full-wave loop, shunt-fed tower

Multi-Operator Class:

K9ZUH	IN	633	52	2	Alpha 1/4-wave vertical
W9CEM	KS	568	55	1	3-phased vertical
LZ2CJ	BU	384		37	Vertical, 4 beverages
WB9SLR	WI	519	53		
NØDKZ	CO	472	52	1	Inverted-L, KLM-160 vertical, longwire, and loop

As we said from the outset, the 5th annual event is now history. The 6th annual contest is just around the corner—scheduled for January 19-20, 1985. Obtain your contest rules and summary sheets today! Do not put it off another minute. Send an SASE to the contest chairman, Harry Arsenault K1PLR, 603 Powell Avenue, Erie PA 18505. Be sure to tell everyone on the band about this big event as it promises to be the biggest and the very best 160 contest going for single sideband. Psssst—tell the DX stations you work that a complete announcement package should appear in the November and December editions of nearly 60 foreign publications. See ya on the air with the new sloper.—*Bill Gosney KE7C.*

160-METER CONTEST SOAPBOX

AA1Q	I prefer CW to phone but this was more fun than I ever thought it would be. The best 160 contest, with lots of activity.
KW2J	To my surprise I found the contest where I expected to find CW and ended up with half the continental US in 6 hours!
WA2SPL	Biggest thrill was working OY8R. Lots of W/VE activity but it still seems DX stations didn't realize there was a contest. Contest was great however—lots of fun! (*Ed. note: we advertised in nearly 60 amateur-radio publications worldwide—most announcements appeared as early as the months of September and October! In the meantime, guess it will take some word-of-mouth info as well—can you help?*)
VE3CDX	This is my first time on 160—got on only 2 days ago.
KC7PA	Where was 1-land? Sure breaks up the winter boredom. I'll definitely be back next year.
KE7C	Lots of activity this year. Met some old friends and made many new ones. My personal thanks to all those who took time out to say hello. Your positive comments about the test are appreciated.
N8AXA/QRP	Anybody who worked me in the contest was doing pretty good. I ran 8 Watts output and had a ball.
N8CGK	There were more hams on 160 this year than I have ever heard before. Hope it stays the "gentlemen's band." Thanks for the contest; it was a blast!
NØDKZ	Best contest ever! Concerned about the DX window, however. Those who choose to observe the window properly are being penalized while those hard-to-get states are being worked between 1.825 and 1.830. By "gentlemen"? (*Ed. note: All we can do is make the window requirement part of our rules. We've done that already. Now let's enforce it. Should we require operators to circle all contacts in their logs which were made in the window? If there were more than 3 US/VE contacts made within the window it would be grounds for disqualification. Should a station fail to list the actual window frequency of a W/VE contact made there and it is found in a cross-checked log, would it be grounds for immediate disqualification? Do we really have to go to this extreme?*)
LZ2CJ	No conditions to the USA. Heard VE1YX and W1FC though!

Edward Island, SI—Sable and St. Paul Islands, PQ—VE2, ON—VE3, MB—VE4, SK—VE5, AT—VE8, BC—VE7, NW—VE8, and YU—Yukon.

SCORING:

American-to-American or Canadian-to-Canadian QSOs count 2 points each, American-to-Canadian (and vice versa) QSOs count 3 points each. The multipliers are the 50 US states, 2 US possessions (Caribbean, Pacific), 10 Canadian provinces, 2 Canadian territories (NWT, YU), and 1 Canadian island (Sable, St. Paul). With 65 multipliers per band, the maximum possible multipliers on all 6 bands is 390.

The final score is the sum of the total QSO points from all bands multiplied by the sum of the multipliers from all bands. Phone and CW sections of the contest are considered separate contests. However, combined score for phone and CW will be used for overall competition. Combined score will be calculated by the contest committee as a result of the addition of phone and CW scores.

AWARDS:

Handsome first-place certificates will be awarded in each multiplier area on both modes in single-operator category. Top five multi-operator stations in each country will receive certificates for high combined phone and CW scores. Where appropriate, the contest committee will

Check log: SP8CC.

award additional awards. All scores will be published in *QST* magazine. Trophies will be awarded the combined single- and multi-operator champions in Canada and the USA.

ENTRIES:

Logs must show all times in GMT. Indicate multipliers the first time only on each band. Log must be checked for duplicate contacts, correct QSO points, and multipliers. Do not use separate logs for each band. Rest periods must be clearly marked in the log. Each entry consists of: log sheets, summary sheet showing all scoring information, category of competition, operator's name and callsign, address of the station, and signed declaration. Entries with over 200 QSOs must include check sheets for each band.

Official logs, check sheets, and summary sheets with multiplier tables are available from the contest chairman; a large SASE with Canadian stamps (or US stamps not glued to the envelope) will bring the samples. Contestants are encouraged to use them; they greatly help with the processing of the entries.

Violation of national amateur-radio regulations or rules of the contest, unsportsmanlike conduct, poor signal quality, taking credit for excessive duplicate contacts, or unverifiable QSOs or multipliers will be deemed sufficient cause for disqualification. Incorrectly logged calls will be counted as unverifiable contacts. Actions and decisions of the CAN-AM Contest Committee are official and final. All entries must be postmarked not later than 30 days after the contest and mailed to: CAN-AM Contest, Box 85, Don Mills, Ontario M3C 2R6, Canada.

MAINE QSO PARTY
Starts: 2300 GMT September 21
Ends: 2359 GMT September 23

Sponsored by the Portland Amateur Radio Association, the contest is open to all. Stations may be worked on phone, CW, and RTTY for each band.

EXCHANGE:

RS(T), serial number, and state, province, country, or Maine county.

FREQUENCIES:

SSB—1870, 3930, 7280, 14280, 21380, and 28580; CW—1810 and 80 kHz up from low end of band; RTTY—3810 and 90 kHz up from low end of band; Novice—3720, 7120, 21120, and 28120.

SCORING:

Complete QSOs count 3 points on CW, 5 on RTTY, and 1 on phone. Out-of-state stations multiply the total number of QSO points by the number of Maine counties contacted (maximum of 16). Maine stations multiply the total number of QSO points by the sum of Maine counties, states, provinces, and countries.

AWARDS:

Certificates will be awarded to top scorers. In addition, this year a trophy will be given to the highest aggregate Maine club score.

ENTRIES:

Mail entries by December 1st to PARA, Box 1805, Portland ME 04104. Applications for the Worked All Maine Counties award may go to the same address.

G-QRP-CLUB CW ACTIVITY WEEKEND
Starts: 0900 GMT September 22
Ends: 2300 GMT September 23

All radio amateurs interested in QRP are invited to take part in the club's activity weekend. No special exchange information was mentioned in the information provided by the club. The operating schedule for this last weekend is as follows:

- 3580 kHz—0900-1000, 1700-1800, and 2200-2300 GMT.
- 7030 kHz—1200-1300, 1500-1600, and 1900-2000 GMT.
- 14060 kHz—1000-1100, 1400-1500, and 2100-2200 GMT.
- 21060/28060—1100-1200, 1600-1700, and 2000-2100 GMT.

Reports on the Activity Weekend are welcomed by Christopher J. Page G4BUE, Alamosa, The Paddocks, Upper Beeding, Steyning, West Sussex BN4 3JW, England.

Full details on membership of G-QRP-Club available from the membership secretary, Fred Garratt G4HOM, 47 Tilshead Close, Druids Heath, Birmingham B14 5LT, England.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

might want to add ten more bits for 1,000 shades of color, too—why be limited to black-and-white pictures?

A full-page picture 10" high might have 130 lines per inch—1300 lines. Each 8" line would be made up of 130 x 8 = 1040 dots. Each dot would require four bits for dot size and ten for color—14 bits. Then we need some housekeeping bits to tell our computers when the information for a dot has started and when it has stopped—16 bits. Shall we add that all up?

1300 x 1040 = 1,352,000 dots for a full-page illustration. Sixteen bits per dot gives us 21,632,000 bits per page. If we send these at 9,600 baud (bits per second), which is very fast these days, we're talking about 2,253 seconds to send that one page—37 minutes. And we gripe at eight seconds for a slow-scan picture!

How would you like to get a magazine over the telephone that way? And 9,600 baud is the very, very top limit of that delivery system. Even a small magazine might take 82 hours. With a dedicated telephone line, you could only get two magazines a week, and think of the line cost!

So we need something with a bit more bandwidth than a telephone wire, which is about the same as a ham voice channel. We need about one thousand times the bandwidth—3 MHz—to get a magazine through in a few minutes. We can do that with microwaves, satellites, cable, or laser and fiber optics. The cable is already in place, so perhaps something can be done to send a magazine via cable. No one has invented a simple system for delivering a magazine by cable or microwave, so that would have to be developed. Someone will probably do that and make a bundle.

A good place to develop something like this is on the UHF ham bands—where 3 MHz isn't a big deal. But we're not bothering to use those bands these days, so they could be blown away soon—just as our 220-MHz band is being blown away because we refused to let the FCC test the no-code-license idea there.

Those microwave channels are desperately needed by the communications industry, and our enormous allocations are sitting there empty, with no real hope of any serious use. Of course, once they're gone, they're gone forever. 160m used to go from 1750 to 2050 kHz; now how much of it do we really have?

Hey, if you'll get hot on 3300 MHz and write some articles, I'll be delighted to print 'em and that, in turn, will get more hams interested in the band. A bit of activity on our now almost unused microwave bands could help save them—if you're game. Are you interested in saving this valuable ham resource?

When you consider the amount of spectrum that is going to be needed for communications in a few years, it's almost too much to grasp. Video conferencing is going to happen, which means that hundreds of thousands of people will be needing several megahertz each for extended periods. That's got to go via laser and fiber optics, for we don't even have enough satellite channels in prospect to handle that kind of volume.

The millions upon millions of computers around the world are going to have to be able to communicate with each other in seconds. This is going to take an elaborate network of repeaters and switching. In the early days, we may be able to make do with satellites, but eventually the volume is going to push the service into a combination of short-range microwaves and fiber optics for the longer hauls.

In the meanwhile, we sit at our ham rigs, trusty key in hand, keeping alive the memory of good old Sam Morse—whose invention was rendered obsolete in 1876 when Bell used his new intercom system to call Watson. I think it is kind of nice to have this living memorial to a quaint old technology—a hundred years old. We're keeping alive some Americana.

In line with that thought, is it really honest to use those newfangled speed keys? I won't even bother to comment on cretins who use electronic keys or those damned typewriter abominations. The old straight key lets the operator's personality come through, right? J-38 forever!

Old timers will remember when hams had a wide range of microwave channels which could be used via satellites. We lost them at the ITU. The League represented us at the conference and you'll find the sorry report in the fine print in *QST*. As Daniels, who was president at the time, said, we didn't do our homework. We lost about 99.99% of our satellite allocations at that time and 100% of our opportunity to ever keep up with technology.

This aggravates me a bit. We're looking at probably a 5% loss of hams this year instead of growth, and our drop in the entry of youngsters is on the order of 80%. The *73* readers who teach school tell me that the kids today are too smart to fall for the Morse-code ploy. Lots of them would like to try ham radio, but their intelligence is offended by the code requirement.

Fortunately for us, the Japanese got rid of the code about twenty years ago, so we'll have the hundreds of thousands of very-well-paid Japanese engineers and technicians it will take to provide our coming communications needs. Their young hams are hard at it, inventing new circuits; you should see their ham magazines—five to six times as thick as anything we have and packed with construction articles every month.

Hey, if you'd like to see for yourself, join me in October (there's just time to get your visas) for a trip to Japan and see their incredible Consumer Electronics Show. The trip, which includes stops at the electronics shows in Taipei, Hong Kong, and Korea, costs about $2,500 and is first class. Drop me a line. I try to get to these shows as well as the two American shows every year so I know what's happening worldwide.

The American shows are

$$ HOME-BREW III $$

Turn your hot solder into cold cash! Once again, *73* is searching for the greatest home-brewer in the land. All projects have a chance to appear in *73*, and the best of the best will be showered with fame and fortune.

Top prize is $250. Second place is worth $100, and three runners-up will each earn $50. Of course, this is in addition to the payment every author receives for publishing in *73*.

Contest Rules

1. Entries must be received by November 1, 1984.
2. To enter, write an article describing your best home-brew construction project and submit it to *73*. If you haven't written for *73* before, please send an SASE for a copy of our author's guide.
3. Here's the catch: The total cost of your project must be $73 or less, even if all parts were bought new. Be sure to include a detailed parts list with prices and sources.
4. Our technical staff will evaluate each project on the basis of originality, usefulness, reproducibility, economy of design, and clarity of presentation. The decision of the judges is final.
5. All projects must be original, that is, not previously published elsewhere. There is no limit to the number of projects you may enter.
6. All rights to articles purchased for publication become the property of *73*.
7. Mail your entries to:

Attn: Home-Brew III

rgely Japanese these days, ne same firms, in all probabil-y, which will be taking over our ommunications: Hitachi, Mat-ushita, Mitsubishi, Toshiba, ony, NEC.

Of course, if there were some vay to get American teenagers nterested in amateur radio ather than popping, snorting, smoking, and sniffing drugs, drinking, watching TV, and other otal wastes of time and money, we might stand a chance. The kids are not going to go for the Morse code—forget that—so do you have any other ideas? I'm stymied.

Kids are not career-oriented enough to spend time doing something or learning something for that reason. They'll work hard at learning if they perceive it as fun and there is an immediate goal which makes sense to them—a goal such as a hobby. None of us who started amateur radio in our teens had any idea of a career; we did it because it was fun and then later found that our hobby just naturally was one hell of a great career bonus. Tomorrow doesn't exist for most kids; why else would so many millions drop out of school? Thus any appeal we may want to make to kids has to be as much on an immediate-reward basis as possible.

You know, if it took two days for pot to work, kids wouldn't bother with it. This immediate-gratification syndrome really has to be reckoned with. We have to understand that kids today just are not brought up to be rewarded next week for work today, so they haven't any patience with taking weeks to learn the code so they can get on the air in an eon or two.

This is a natural response for kids, so we shouldn't be surprised. I suspect that a couple of generations ago, when the radio was blaring fourteen hours a day in homes instead of the TV, perhaps we taught kids the benefits of patience. Now, with the parental eyes and attention on "Dallas" and "Falcon Crest," most kids are brought up with little more than their natural inclinations to guide them, no matter how destructive.

If you had no fear of addiction, mightn't you try cocaine and heroin? Well, when tomorrow isn't real, addiction isn't real, so what's the worry?

Perhaps, as the editor of a ham magazine, I hear a lot more than you do from people who have tried (some for years) to learn the code. Some have dyslexia, some have trouble getting the two sides of their brain to cooperate—and the learning of the code is an incredibly complex use of the brain. Some people can learn the code in a few minutes—it took me less than a half hour to learn the characters and just a few hours of practice to get to 13 per. Things like that are easy for me. Yet I've known several people who wanted ham licenses so bad they would almost have killed for them and yet they never were able to manage the code.

Despite the irrelevancy of amateur radio today, we've managed to hold our low bands pretty well. I'd chalk that up more to bureaucratic bungling and the virtual death of the American consumer electronics industry, which is the group that normally would be fighting for our frequencies. If they were alive, they'd be grabbing for our bands in a minute and we'd have little argument to stop them—and less power. There are less active amateurs today than owners of Timex computers.

So, as I turn on my rig to see if Eva has her list all set for another DXpedition, I know that it's likely that I'll be able to ham for a few more years. Who knows, perhaps satellites and fiber optics will save our low bands and even take the pressure off some microwave bands. But the growing number of mobile services are going to take all of the old television channels and more as TV is moved to fiber-optic cable or direct-broadcasting satellites.

People walking or driving around are going to want to communicate. We know that from the ham use of repeaters. It's rare these days to see a ham without at least one HT on his belt and at Dayton some have a half dozen dangling. Many groups bring their own repeaters to Dayton—heaven forbid they should lose contact with members of the club somewhere out in the flea market.

We see the beginnings of this with cellular radio. If I can talk with someone a hundred miles away while skiing down a mountain in Colorado or New Hampshire (and I've been doing that for 15 years now), you can bet that the businessman is going to make sure that he can do at least that. It'll take a while to organize—it will require a lot of channels and it will sell an incredible amount of Japanese equipment.

Yes, I see this coming and it is frustrating. The League won out on the Morse code, so now I don't know of any way to get ham clubs started in high schools. They have them in every high school in Japan, as you already know. And, yes, I know that a good many hams won't agree with me, but I'll bet none of 'em will be specific about where they disagree.

On the code? We have as clear proof as anyone could ask for in the Japanese example of what happens when you eliminate the code test. They have licensed about one and a quarter million hams so far. Oh, yes, the Japanese are different. Yep, I've heard that. Well, it's true, apparently. IQ tests seem to indicate that they have an intelligence lead on us of about ten points on the average, according to the scientific reports. They sure seem to have done the smart thing in eliminating the code from the ham exams.

I'm writing this editorial on a Radio Shack computer, designed and made in Japan. I print it out on a C. Itoh printer, designed and made in Japan. I am wearing a Seiko UC-2000 computer watch, designed and made in Japan. MY CD player in the corner is by Sony, designed and made in Japan. My hi-fi and TV sets are by Hitachi, designed and made in Japan. My ham rig is a Kenwood, and you know who designs and makes all our ham gear as well as I do. None of these is a copy of an American invention; they are all creative developments and most of them were done by Japanese who started out as hams in high school a few years ago while we were killing ourselves off with the Morse code.

Anyone out there game to petition the FCC to reconsider their mistake with the no-code proposition?

NEW TECHNOLOGY

Let me see some hands: How many of you know about Compact Discs—CDs? These were probably the biggest hit of the recent Summer Consumer Electronics Show in Chicago. These are the first digital audio recording medium and once you hear a CD, you will be all through buying LP records. The difference is that great. I've been enough impressed with the difference to

See List of Advertisers on page 98

get a magazine started to support this new industry—*Digital Audio.*

But the CD has even more prospects than as a whole new start for hi-fi. We'll be seeing these discs used for data storage for computers and even as low-cost interactive video players. The material is stored digitally on the disc and then read with a laser beam, so there's no wear on the record no matter how many times it is played.

Interactive video is the best delivery system we've yet found for reducing the cost and improving the quality of education. I attended a symposium on the subject recently at Dartmouth and enthusiasm is high in the educational community for the interactive video disc potential. Maybe I should start a magazine, eh? Not yet.

If you're an entrepreneur and want to know what technology is going to explode next, I'll tell you. There are opportunities for hundreds of small firms to get started with products in this new field and make millions. This is the briefcase, lap, or kneetop computer. Businessmen all have to do homework. It won't take long before they discover that these small computers will help them enormously to write, do business plans, schedule, work on spread sheets, communicate, and so on. I predict that within two years there will be more of these small computers sold than desktops.

These computers need software, accessories, small printers, and information just like the desktop computers did. In a couple of years, most of the businessmen you know will have one or even two. I already carry around two most of the time—they do slightly different things. I use 'em in the car, on planes, and when I have a few minutes to wait for someone. Most of you have been ignoring my exhortations for you to get into business and make money for years, so I'm used to it. But I do get a lot of pleasure when someone says hello at a hamfest or other show and claims my editorials got them off dead center and helped make them rich. I can put up with an awful lot of old hams (poor hams, I should add) grumbling about not agreeing with me when I hear that now and then.

WAYNE GREEN ALUMNI REUNION

If you know anyone who has worked for me over the last 24 years, have them get in touch. I'm organizing a special dinner meeting at the November Comdex in Las Vegas so we can get together for a reunion. Hey, next year is the 25th anniversary for *73.* Not many magazines survive that long.

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

ON THE ROAD AGAIN

Now that the FUN! poll tabulations are completed, we can get back to the business at hand. Now, where was I? Oh, yeah. EPCOT Center. I visited Walt's final brainstorm last April while in Florida to cover a space-shuttle launch for another magazine.

You would think that Mr. FUN! would have fun at a place like EPCOT, right? Well, I did—in a way. I couldn't stop laughing at all of the stupid exhibits. Experimental Prototype Community of Tomorrow? Only if Kodak, GM, and AT&T decide to rework our neighborhoods. Frankly, the place is nothing but a big trade show glopped with the usual Disney hokum. The food at the various restaurants was good, but the rest of my visit was a waste.

Now, don't get me wrong. I'm not against big business. I like money as much as anyone (perhaps more so), but I just can't see how EPCOT is going to help us change the world. It may show us the glories of a few multinational corporations, but it'll take a lot more than a 3-D movie and some talking dummies to lead us into the third wave. Anyway, how can you take the place seriously when its communications exhibit includes a revolving cover of *CQ Magazine*? Really! Take my word; stay away.

My spring travels also took me to Washington DC and the Smithsonian's revamped Museum of American History. Make a note to hit this place the next time you visit Disney World by the Potomac. The displays of early radio, telegraph, and computer equipment are superb and bound to thrill any red-blooded ham. Sadly, NN3SI, the Smithsonian's ham station, was unattended the day I visited. Quite a pity. It was a Saturday and the place was loaded with spring tourists. C'mon guys, let's get our act together. If I had had my ticket with me, I would have sought someone out for permission to operate.

This month's column is about nothing in particular—just some random quizzes on random topics.

ELEMENT 1 MULTIPLE CHOICE

1) By now we all should know that Hiram Percy Maxim W1AW was a founder of the American Radio Relay League, back in 1914. But who was the League's co-founder?
   1) Herbert Hoover
   2) Clarence Tuska
   3) Franklin Gothic
   4) Urban Hewitt

2) What were the official Conelrad frequencies?
   1) 14.090 and 21.090 MHz
   2) 540 and 880 kHz
   3) 640 and 1240 kHz
   4) 710 and 1600 kHz

3) The word "Conelrad" stands for:
   1) Consolidated emergency limited radio system
   2) Connected electronic radios
   3) Control of electromagnetic radiation
   4) Consolidated electronic radiation network

4) You'll find the "Graveyard" on:
   1) 20 meters
   2) 11 meters
   3) 160 meters
   4) the AM broadcast band

5) Radio Peace and Progress broadcasts from:
   1) The United States
   2) China
   3) The Soviet Union
   4) Taiwan

ELEMENT 2 SCRAMBLED WORDS

Unscramble these terms related to shortwave listening:

tactis	arlye	golrnef
breactila	saeservo	renegein
granpopada	tenrenvomg	gaugelan
tralveni	loseglurl	micus
telnis	gorparm	domsecti
dbna	licensetand	plisrotac
drabsocat	luitities	

ELEMENT 3 TRUE-FALSE

	True	False
1) Howard Hughes was a ham.	____	____
2) Andy Devine was a ham.	____	____
3) Harry Truman was a ham.	____	____
4) The first Dayton Hamvention was held in Columbus.	____	____
5) The FCC allows W1AW to use up to 10,000 Watts of power during code-practice sessions.	____	____
6) The planet Jupiter can be heard on 21 MHz.	____	____
7) SINPO is a system used to determine a received signal's quality.	____	____
8) The Voice of America is operated by a private company.	____	____
9) The electrical term "siemens" used to be known as "mho."	____	____
10) A triode has two elements.	____	____

ELEMENT 4 ALPHABET GAME

Complete the words below by placing letters of the alphabet on each dash. Use each letter only once.

A B C D E F G H I J K L M
N O P Q R S T U V W X Y Z

1) _OULE
2) _O_
3) _IP_LE
4) SC_E_AT_C
5) _I_O_AT_
6) PERM_A_ILIT_
7) _U_ERRE_ENER_TIVE
8) _RE___EN_Y
9) _E_E_

THE ANSWERS

Element 1:
1—2 But HPM got all the publicity.
2—2 So it says on the radio in my '62 Chevy Impala convertible. Nice car. Dated radio.
3—3 In theory, it was supposed to keep enemy aircraft from zeroing in on a town or city.
4—4 At the upper end of the band, where the FCC lumps low-powered broadcasters.
5—3 Yeah, right.

Element 2:
(Reading from left to right): static, relay, foreign; calibrate, overseas, engineer; propaganda, government, language; interval, religious, music; listen, program, domestic; band, clandestine, tropicals; broadcast, utilities.

Element 3:
1—True 6—True
2—True 7—True
3—False 8—False
4—False 9—True
5—False 10—False

Element 4:
1—JOULE
2—VOX
3—DIPOLE
4—SCHEMATIC
5—KILOWATT
6—PERMEABILITY
7—SUPERREGENERATIVE
8—FREQUENCY
9—ZENER

SCORING

Element 1:
Five points for each correct answer.
Element 2:
One point for each unscrambled word.
Element 3:
Two and one-half points for each correct answer.
Element 4:
Two and one-half points for each word completed.

How did you do?
1-20 points—Amazing. You can read!
21-40 points—Not good
41-60 points—Not bad
61-80 points—Pretty good
81-100 points—Want to take over the column?

RCA VOLT-OHMS WV97A $30, WV77C $20. Old HRO coil set $70. Beckman pH

meter $25. K6KZT, 2255 Alexander, Los Osos CA 93402. BNB194

ANTENNAS WANTED: We pay cash for surplus amateur and CB antennas. Must be in original boxes and in reasonably good condition. Send a list or call: H. C. Van Valzah Co., 1140 Hickory Trail, Downers Grove IL 60515. BNB195

SALE—COMPLETE OPERATING STATION —Mint Drake R4B-T4X, power supply, switching console with phone patch, filtered pair 813s 10-80 linear, 3-kV power supply, all cables, relays, manuals: $800. W2ETB; (212)-833-0139. BNB196

NEW HAM-SWL SOCIETY for unity of thought & learning. Open to all. Many topics, awards, free ad space in periodical, society net, museum participation. Shack pics & QSLs welcome. Writers needed. SASE for info to RCSW, 32 Applegate, Bennington VT 05201. BNB197

KT5S SUPER DX SLOPER 80-10m only $59.95. KT5B multiband dipole 160-10m only $59.95. 2-kW roller inductor (28 uH) $47.50. Weather-boot kit (PL-259) $8.95 p.p. Much more! Info available. Kilo-Tec, PO Box 1001, Oak View CA 93022; (805)-646-9645. BNB198

WANTED: E.H. SCOTT RADIO—1935/1940 vintage. Either 23-tube All-Wave or Philharmonic. Must be in excellent condition. Will pay shipping charges. J. Fred Belles, 8563 Peebles Road, Pittsburgh PA 15237. BNB199

COLOR COMPUTER OWNERS—Free software and hardware catalog. Spectrum Projects, PO Box 9866, San Jose CA 95157-0866. BNB200

ROHN TOWERS—wholesale direct to users. 23% to 34% discount from dealer price. All products available. Write or call for price list. Also we are wholesale distributors for Antenna Specialists, Regency, Hy-Gain. Hill Radio, 2503 G.E. Road, PO Box 1405, Bloomington IL 61701-0887; (309)-663-2141. BNB201

FANTASTIC DISCOUNTS—Icom, Kenwood, Yaesu, Sony, MFJ, Panasonic, Uniden, Bearcat, Regency, antennas, coax, CW/RTTY decoders, marine, more!! Free UPS shipping & insurance to 48 states. 25-page picture catalog $1.00 (refundable). Galaxy Electronics, Box 1202 67 Eber Ave., Akron OH 44309; (216)-376-2402 9-5 pm EST. BNB202

SPACE-SHUTTLE COMMENTARY

The Spaceport Amateur Repeater Club (SPARC) has been authorized by AMSAT to transmit space-shuttle-mission commentary for all missions on Special Services Channel H2 (145.963 MHz) of AMSAT-OSCAR 10. SPARC, through the facilities of K4GCC and WB4ZXS, will provide space-shuttle-mission audio for several hours each as time permits. All amateur-radio operators are invited to submit reception reports to: SPARC, PO Box 872, Merritt Island FL 32952. (de Carl AA4MI)

HAM IN SPACE—TAKE 3

Yet another amateur has been chosen by NASA for the space-shuttle program. This time it's Dr. Ron Parise WA4SIR. Ron's contract calls for at least two missions, the first being 61F scheduled to fly in March, 1986. Ron is very active in AMSAT and has been science coordinator for the UO-9 project. Regarding amateur-radio operation from the shuttle, Ron says he is "enthusiastic" and looks forward to bringing some radios aboard. Possible follow-up flights may include missions in November, 1988, and July, 1987.

SPACE TRAFFIC CONTROL

AMSAT may soon need to sponsor a permanent ham in space just to direct traffic. Plans for the next year or so call for several new satellites including Phase IIIC, ARSENNE, JAS-1, PACSAT, and hopefully a parasitic geosynchronous system. Add these to the birds already orbiting (OSCARs 9, 10, 11, and six RS-series) and we've made quite a contribution to the already-present congestion. Any volunteers?

TIMELY INFORMATION

Up-to-date information on all aspects of satellite operation may be obtained by tuning in to one of AMSAT's information nets. Times are in UTC and frequencies are in kHz:
0200 Tuesday on 3850
1900 Sunday on 14282
1800 Sunday on 21280
0300 Wednesday on 3850
0400 Wednesday on 3850

You may also receive late-breaking news by copying the ARRL bulletin. For a complete schedule of ARRL transmissions, send an SASE to the League at 225 Main Street, Newington CT 06111.

Thanks to *Amateur Satellite Report* for this month's information.

AWARDS

SUBMARINERS

The DuPage Amateur Radio Club will be operating a special-event station, W9DUP, in honor of the 30th annual convention of the US Submarine Veterans of World War Two from Wednesday, August 29, through Saturday, September 1, 1984, from the submarine *USS Silversides* which is docked as a War Museum alongside Navy Pier in Chicago.

Hours of operation will be from 1100 to 0300 UTC daily on 10 through 80 meters and also two meters. For a commemorative certificate send $1.00 and a #10 SASE to DARC, PO Box 71, Clarendon Hills IL 80515.

WINO AT WORLD'S FAIR

The Wireless Institute of New Orleans (WINO) will be operating a special-event station at the Louisiana World Exposition on August 31 and September 1. The "Wonderful WINO Weekend at the World's Fair" will enable hams around the world to contact the World's Fair amateur radio station, K5WF, on the Friday and Saturday nights preceding Labor Day, from 10:00 pm CDT until 2:00 am CDT.

Contacts will be on the forty-meter band, LSB, on or near 7.240 MHz. Propagation permitting, K5WF will also be on 75 and 20 meters.

Special commemorative QSL/Certificates confirming contacts will be available for an SASE to: WINO, Box 6541, New Orleans LA 70174.

LAKE COUNTY ARS

The Lake County Amateur Radio Society will have a special-event station, N6GJM, at the Lake County Fairgrounds on August 31 through September 3, 10:00 am to 10:00 pm PDST.

Operating frequencies will be 10 to 20 kHz above the bottom portion of CW and phone bands, 15 through 80 meters.

A special certificate is available for an SASE to KR8G, PO Box 682, Cobb CA 95426.

OK CORRAL, TOMBSTONE, COCHISE COUNTY, ARIZONA

A special-event station will again operate from the heart of the OK Corral, in conjunction with the third annual Rendezvous of The Gunfighters, September 1, 2, and 3, 1984.

The OK Corral was the site of the famous shoot-out between the Earp and Clanton factions in 1881. Operations, cosponsored by KB7KZ and the Old Pueblo Radio Club will begin at 1500 UTC, September 1, and run through 2200 UTC, September 3, on CW and SSB. Frequencies: SSB—28880, 21380, 14280, 7280; CW—21130, 7130.

A certificate will be awarded to all who work us as well as SWLs. Please send a large 8-1/2" × 11" SASE (40 cents postage) to: KB7KZ, PO Box 36032, Tucson AZ 85740.

LOCOMOTIVE MOBILE

The Northern New Mexico Amateur Radio Club will hold its 2nd annual steam-locomotive mobile operation on the Cumbres and Toltec Railroad, September 8, 1984, de 1000 MST to 1630 MST. Frequencies of operation will be 14.225 MHz and 7.225 MHz. The train will travel from Antonito CO to Osier CO and back, crossing the NM and CO border 10 times. If you wish to join us, contact Daryl Grant W7LHO, 1885 Camino Lumbre, Santa Fe NM 87502.

HONORING BEAR BRYANT

The West Alabama Amateur Radio Society (WAARS) will operate the 2nd annual special-event station on Saturday, September 8, in commemoration of the greatest college football coach in history, Paul "Bear" Bryant.

The Bear Bryant special-event station will operate from the campus of the University of Alabama. WAARS will operate using the callsign KE4TN from 1300Z to 2400Z on that date.

Phone frequencies will be the bottom 25 kHz on the General 40-10-meter phone band. The club will also work Novices on the bottom 25 kHz of the Novice band. The club will offer a handsome commemorative certificate of the event to any station worked. Send $1 and a large SASE to the West Alabama ARS, PO Box 1741, Tuscaloosa AL 35403.

MARK TWAIN ARA

The Mark Twain ARA will operate W0KEM from 1400Z to 2300Z on September 8th and 9th to celebrate the dedication of the 20,000-acre Mark Twain Lake and Clarence Cannon Dam in east-central Missouri.

Phone operation will be in the lower 25 kHz of the 40-, 20-, and 15-meter General bands, also Novice operation in the 40-meter band. For certificate send a legal-size SASE to Mark Twain ARA, PO Box 56, Center MO 63436-0056.

OCEAN MONMOUTH ARC

Ocean Monmouth Amateur Radio Club (OMARC) will operate KC2Q from 1600Z on September 22, 1984, until 1600Z September 23, 1984, from the Guglielmo Marconi Memorial Tower which was used during early transoceanic receiving experiments. Frequencies: 3.965, 7.265, 14.265, 21.365, 28.565. For a QSL send an SASE, or for a certificate and a QSL send $1.00 to KN2B, 18 Gardners Lane, Manasquan NJ 08736.

PAUL BUNYAN FESTIVAL

The Paul Bunyan Wireless Association and the Brainerd Area Amateur Radio Club will be sponsoring a special-event station from the site of the Paul Bunyan Festival near Brainerd MN. Operation will be from 1800Z on September 22, until 2100Z on September 23. Operation will be in the lower portions of the General-class phone bands of 40-10 meters. For a commemorative QSL, send QSL and SASE to Rick Paine KC0YG, PO Box 354, Pequot Lakes MN 56472.

MOUNTAIN STATE AWARD

The Logan County ARC will hold its fourth annual Mountain State Award expedition from 1600 UTC on September 22, until 0200 UTC September 23, 1984. The callsign will be W8VEN.

Phone operating frequencies will be approximately 25 kHz from the low end of the General phone 80- and 40-meter bands as propagation allows.

A handsome 8" × 10" certificate will be awarded to all contacts submitting a QSL and legal-size SASE to Robert T. Johnson W8VEN, PO Box 320, Stollings WV 25646.

DR. DIGITAL

Robert Swirsky AF2M
PO Box 122
Cedarhurst NY 11516

MAILBAG

Every so often, I look through the letters I receive. It always amazes me to see all the silly things I am asked to do—debug programs, design hardware, or write software. Today, I got what is by far the most interesting letter. It reads:

Dear Dr. Digital,

I never thought I'd be writing to you, but the problem persists. In the cold of winter, they freeze over and I can't do a thing with them; in the summer, they curl up and wrinkle. Please, Dr. Digital, I need help. My digits bother me so.

Besides all that—other people place *their* digits on top of mine! Really, Doctor, can't anything be done? They, of course say (mumble) "Excuse me," "S'cuse me," or "S'rry," but my digits ache anyway.

HELP!

Unfortunately, the letter had no signature or return address, so I'll have to reply in the column:

Dear Friend,

I think I have a solution to your problem that will reduce your digital problems by twenty percent *and* make you a better computer programmer.

My idea is this: Have two of your fingers removed. This way there will be fewer fingers to give you grief. In addition, you'll be a whiz with octal (base 8) notation. If you program in assembly language, base 8 will come in handy.

Your Friend,
Dr. Digital

REAL PROGRAMMERS

Are you a real programmer? There has been much written on what separates the real hams from the appliance operators, but not on how to tell the real programmers from the hackers. I offer the following guidelines. See how many *you* follow. Real programmers...

- Use FORTRAN II
- Use Intel Mnemonics for Z-80 work
- Never use comments
- Can read paper tape
- Use obscure tricks
- Use DSEGs
- *Understand* the USING directive
- Can get out of Witt's End
- Prefer TECO or CP/M ED
- Know RSX-11M
- Never upgraded their computers from CP/M 1.4
- Don't sign licensing agreements
- Program in uppercase
- Slash the letter "O" and not the number zero
- Use 8" SSSD floppy disks
- Program off the front panel
- Feel PL/M is too high level
- Play TOPS-10 Adventure, Lunar Lander, and nothing else
- Use Dijkstra's picture for a dartboard
- Call by name
- Program for fun
- Have an autographed picture of Knuth
- Take their work home
- Are usually poor

WE INTERRUPT THIS PROGRAM...

For the past few months, I've been discussing some ways computers are interfaced to external equipment, such as amateur-radio hardware. This month, I will continue the discussion with a description of interrupts.

If you've written programs of any sizable length, you have probably divided your code into subroutines. A subroutine is a section of code that is to be executed a number of times during a program's execution. It is invoked by a statement such as CALL, GOSUB, or JSR. For example, in 6502 assembly language, a subroutine call looks like this:

```
JSR SUB1
```

When this statement is executed, a number of things happen. First, the content of the program counter is stored in a special memory location called the stack. The program counter is a special register within the microprocessor that contains the address of the *next* instruction to be executed. After this is done, the address of the subroutine "SUB1" is loaded into the program counter. This causes the computer to branch to the subroutine.

After the subroutine is finished, program execution returns to the statement after the calling JSR. In 6502 assembly language, this is accomplished with the RTS (return from subroutine) statement. For example, subroutine SUB1 might look like this:

```
SUB1  CLC
      LDA #03
      ADC #99
      STA XYZ1
      RTS
```

The RTS essentially "undoes" the JSR statement. It takes the value of the program counter that was stored on the stack by the JSR statement and loads it back into the program counter. This causes the computer to resume program execution at the statement after the JSR Because of the way that the contents of the program counter are stored, the subroutine can be called from any part of the main program and it will be able to return control to the main program.

Now that we have the concept of a subroutine out of the way, we can begin to look at interrupts. An interrupt is similar to a subroutine except that an external event, not a program call, causes it to begin execution.
